This work is provided “as is,” and the publisher disclaims any and all

warranties, express or implied, including any warranties as to accuracy, comprehensiveness, or currency of the content of this work.

This work is no substitute for individual patient assessment based upon healthcare professionals' examination of each patient and consideration of, among other things, age, weight, gender, current or prior medical conditions, medication history, laboratory data and other factors unique to the patient. The publisher does not provide medical advice or guidance and this work is merely a reference tool. Healthcare professionals, and not the publisher, are solely responsible for the use of this work including all medical judgments and for any resulting diagnosis and treatments.

Given continuous, rapid advances in medical science and health information, independent professional verification of medical diagnoses, indications, appropriate pharmaceutical selections and dosages, and treatment options should be made and healthcare professionals should consult a variety of sources. When prescribing medication, healthcare professionals are advised to consult the product information sheet (the manufacturer's package insert) accompanying each drug to verify, among other things, conditions of use, warnings and side effects and identify any changes in dosage schedule or contraindications, particularly if the medication to be administered is new, infrequently used or has a narrow therapeutic range. To the maximum extent permitted under applicable law, no responsibility is assumed by the publisher for any injury and/or damage to persons or property, as a matter of products liability, negligence law or otherwise, or from any reference to or use by any person of this work.

PREFACE

On the last Friday of the nursery rotation at UCSF Benioff Children's Hospital, the third-year medical students are given an assignment which seems simple at first. For this final task, the students are asked to present a talk on any pediatric newborn topic of their choice. One of the parameters is that the presentation can only be 3 minutes in length, at most. Surely, one would think that the brevity of the talk might make the presentation that much easier and quicker to prepare. However, as many students eventually discover, it is actually much more challenging to teach something of substance with so little time. For a short presentation, there is limited time to discuss the key concepts or pathophysiology about the condition as well as the most important diagnostic or therapeutic issues. From large heaps of information, students need to select only the most important information to present on Friday morning. Choices need to be made, and students learn to become connoisseurs of which clinical facts are worthy of presentation. This assignment highlights the difficulty in keeping our explanations concise as well as the art and skill of efficient clinical teaching. Although Mark Twain was not an academic pediatrician, I think he recognized this irony of efficient communication when he once quipped, "I didn't have time to write a short letter, so I wrote a long one instead."

I have always been impressed by my teachers and colleagues who could so easily and so efficiently teach with so little time. These colleagues could punctuate rounds with the most wonderful few minutes of teaching and their consultations have always been the most valuable over time. This book, *The 5-Minute Pediatric Consult*, can be thought of as a collection of all those insightful and efficient consultations all placed into one book. The authors of each chapter strive to provide a comprehensive, but efficient, 5-minute consult for a busy clinician.

It is an honor to continue this tradition of *The 5-Minute Pediatric Consult* with this new seventh edition. M. William Schwartz, MD, at the University of Pennsylvania, Perelman School of Medicine, edited the initial editions of the book and established a comprehensive and

indispensable resource for health care professionals who care for children. The first edition was published in 1997. Throughout the last two decades, the continuing popularity of *The 5-Minute Pediatric Consult* is a testimony to the outstanding work of the previous authors and editors as well as the production staff.

Once again, the seventh edition continues to innovate and build on previous editions. For this new edition, our editorial review now includes an additional pharmacologic review by Carlton K.K. Lee, PharmD, MPH. We have also expanded the content for several topics with additional chapters, including pediatric dental health issues (e.g., Dental Caries, Dental Health and Prevention, Dental Infections) and psychiatric conditions (e.g., Depression, Separation Anxiety Disorder, Trichotillomania) as well as new chapters for a variety of conditions (e.g., Cyclic Vomiting Syndrome; Ankyloglossia; Diabetes Mellitus, Type 2). Some chapters have been reorganized to reflect broader clinical situations that a clinician may face (e.g., Hypercalcemia, Hypocalcemia, Hyperleukocytosis), and other topics reflect new therapies available to clinicians (e.g., Prebiotics).

Several new topics reflect the changing epidemiology of childhood illness and pediatric care, in general. With the growing success of pediatric cancer treatment, four of five children with childhood cancer now achieve long-term survival. In addition, nearly two thirds of survivors develop chronic health issues related to their previous diagnosis and treatment. As a result, we have added a topic on Cancer Therapy Late Effects for primary care and subspecialty clinicians who care for these children. In addition, the care of former premature infants is quite common in pediatric practice. We have added topics such as Meconium Aspiration Syndrome, Neonatal Encephalopathy, Respiratory Distress Syndrome, and Retinopathy of Prematurity. Although these are clinical topics primarily addressed in the neonatal intensive care unit (NICU), many primary care clinicians who care for former “NICU-graduates” may appreciate information and clinical pearls on issues associated with the disease prognosis, follow-up, or ongoing care.

Finally, we realize that many clinicians who use this book also play a key role in the clinical teaching and instruction of trainees at all levels.

With this issue in mind, Terry Kind, MD, MPH, has created and developed “The 5-Minute Educator,” which is also included in this book. The four topics (Precepting, Direct Observation, Feedback, and Clinical Reasoning) are authored by seasoned educators who provide efficient, practical and accessible consultation on how to be a more effective clinical educator in a busy clinical setting.

With all these changes, this edition now includes more than 500 topics and features a group of new as well as returning authors. These authors have demonstrated great skill in distilling large amounts of information into an easily accessible 5-minute synopsis or “consult” on a plethora of clinical topics. Although the topics are a short two pages, each topic represents years of clinical experience as well as countless hours of research, writing, and editing.

To organize this effort, I am also fortunate to have a wonderfully diverse, distinguished, and talented team of associate editors, who have recruited such accomplished authors for each topic. Ronn E. Tanel, MD, has the distinction of serving as an associate editor on previous editions of this book and has provided wonderful continuity for this project. The new associate editors include Paul Brakeman, MD, PhD; Megan L. Curran, MD; Linda A. DiMeglio, MD, MPH; W. Christopher Golden, MD; Robert E. Goldsby, MD; Adam L. Hartman, MD; Terry Kind, MD, MPH; Carlton K.K. Lee, PharmD, MPH; Jenifer R. Lightdale, MD, MPH; and Camille Sabella, MD. This group is a “dream” team of clinicians, educators, editors, and scholars. They have already taught me so much with each comment on each draft of each chapter they edited and reviewed. Finally, I would also like to thank the staff at Absolute Service, Inc., and Wolters Kluwer including Rodel Fariñas, Rebecca Gaertner, Ashley Fischer, and Jamie Elfrank, who have organized and presented this work so beautifully.

In the preface to the sixth edition of *The 5-Minute Pediatric Consult*, Dr. Schwartz wrote,

“Being involved in many ways with educating medical students . . . and visiting many hospitals, I was able to see firsthand how this book was helpful to trainees, primary care pediatricians, and nurses, and thus, justifying the name of *The 5-Minute Pediatric Consult*.”

As one of the many trainees and primary care pediatricians who

benefited from the previous editions of The 5-Minute Pediatric Consult, I hope that this new edition will continue to be a useful clinical companion and continue to help another generation of trainees and health care providers who care for children.

Diva D. De León, MD, MSCE

Associate Professor
Department of Pediatrics
Perelman School of Medicine at the University of Pennsylvania
Director, Congenital Hyperinsulinism Center
Division of Pediatric Endocrinology
The Children's Hospital of Philadelphia
Philadelphia, Pennsylvania

Jeannine Del Pizzo, MD

Assistant Professor of Clinical Pediatrics
Department of Pediatrics
Perelman School of Medicine at the University of Pennsylvania
Division of Emergency Medicine
The Children's Hospital of Philadelphia
Philadelphia, Pennsylvania

Sophia D. Delpe, MD

Resident
Department of Urology
Yale–New Haven Hospital
New Haven, Connecticut

Michelle Denburg, MD, MSCE

Professor of Pediatrics
Department of Pediatrics
Division of Nephrology
The Children's Hospital of Philadelphia
Philadelphia, Pennsylvania

Craig DeWolfe, MD, MEd

Assistant Professor
Department of Pediatrics
The George Washington University School of Medicine & Health
Sciences
Medical Unit Director, Main Pediatric Hospitalist Division
Children's National Health System
Washington, DC

Katherine Deye, MD

Assistant Professor
Department of Pediatrics
The George Washington University School of Medicine & Health
Sciences
Pediatrician

Freddie Mac Child and Adolescent Protection Center
Children's National Medical Center
Washington, DC

Jennifer DiPace, MD

Assistant Professor
Director, Pediatric Graduate Medical Education
Department of Pediatrics
New York-Presbyterian/Weill Cornell
New York, New York

Michael DiSandro, MD

Professor
Department of Urology
University of California, San Francisco
Staff
Department of Urology
UCSF Medical Center
San Francisco, California

Mark F. Ditmar, MD

Clinical Associate Professor of Pediatrics
Jefferson Medical College
Philadelphia, Pennsylvania
Department of Pediatrics
Southern Ocean Medical Center
Manahawkin, New Jersey

Stacy E. Dodt, MD

Pediatric Endocrinology Fellow
Division of Endocrinology and Diabetes
The Children's Hospital of Philadelphia
Philadelphia, Pennsylvania

John P. Dormans, MD

Professor

Department of Orthopaedic Surgery
Perelman School of Medicine at the University of Pennsylvania
Chief
Division of Orthopedic Surgery
The Children's Hospital of Philadelphia
Philadelphia, Pennsylvania

Morna J. Dorsey, MD, MMSc

Associate Professor
Department of Pediatrics
University of California, San Francisco
Clinical Director, Allergy & Immunology
Department of Pediatrics
UCSF Benioff Children's Hospital San Francisco
San Francisco, California

Monica D. Dowling, PhD

Assistant Professor of Clinical Pediatrics
Department of Pediatrics
University of Miami Miller School of Medicine
Miami, Florida

Colleen A. Hughes Driscoll, MD

Assistant Professor
Department of Pediatrics
University of Maryland School of Medicine
Baltimore, Maryland

Nancy Drucker, MD

Associate Professor
Department of Pediatrics
University of Vermont
Pediatric Cardiologist
Department of Pediatrics
Fletcher Allen Health Care
Burlington, Vermont

Steven G. DuBois, MD, MS

Associate Professor

Department of Pediatrics

University of California, San Francisco

Attending Physician

Department of Pediatrics

UCSF Benioff Children's Hospital San Francisco

San Francisco, California

Alcia Edwards-Richards, MD

Fellow

Department of Pediatric

Division of Pediatric Nephrology

University of Miami Miller School of Medicine

Miami, Florida

Deborah B. Ehrenthal, MD, MPH, FACP

Lifecourse Initiative for Healthy Families Endowed Chair

Visiting Associate Professor

Departments of Obstetrics & Gynecology, Population Health Sciences, and
Medicine

School of Medicine and Public Health

University of Wisconsin-Madison

Madison, Wisconsin

Jorina Elbers, MD

Assistant Professor

Departments of Neurology and Neurological Sciences

Stanford University

Stanford, California

Assistant Professor

Child Neurology

Lucile Packard Children's Hospital Stanford

Palo Alto, California

Scott Elisofon, MD

Instructor
Department of Pediatrics
Harvard Medical School
Attending Physician
Division of Gastroenterology, Hepatology, and Nutrition
Boston Children's Hospital
Boston, Massachusetts

Gary A. Emmett, MD

Professor
Director of Hospital
Department of Pediatrics
Thomas Jefferson University Hospital
Philadelphia, Pennsylvania

Heidi Engel, DPT, PT

Assistant Clinical Professor
Department of Physical Health and Science
University of California, San Francisco
Physical Therapist
UCSF Rehabilitative Services
UCSF Medical Center
San Francisco, California

Jessica E. Ericson, MD

Pediatric Infectious Diseases Fellow
Department of Pediatrics
Duke University
Duke Children's Hospital
Durham, North Carolina

Erica A. Eugster, MD

Professor of Pediatrics
Department of Pediatrics
Indiana University School of Medicine
Director, Section of Pediatric Endocrinology

Riley Hospital for Children at Indiana University Health
Indianapolis, Indiana

Stephen J. Falchek, MD

Division Chief
Division of Pediatric Neurology
Department of Pediatrics
Nemours Alfred I. duPont Hospital for Children
Wilmington, Delaware

Marni J. Falk, MD

Assistant Professor of Pediatrics
Department of Pediatrics
The Children's Hospital of Philadelphia
Philadelphia, Pennsylvania

Rima Fawaz, MD

Instructor in Pediatrics
Harvard Medical School
Attending Physician
Medical Director, Intestine and Multivisceral Transplant
Division of Gastroenterology, Hepatology & Nutrition
Boston Children's Hospital
Boston, Massachusetts

Kristen A. Feemster, MD

Assistant Professor
Department of Pediatrics
Perelman School of Medicine at the University of Pennsylvania
Attending Physician
Division of Infectious diseases
The Children's Hospital of Philadelphia
Philadelphia, Pennsylvania

Daniel E. Felten, MD, MPH

Assistant Professor

Department of Pediatrics
Washington University Medical School
Pediatrician
Department of General Pediatrics
Children's National Medical Center
Washington, DC

James Feusner, MD

Medical Director, Oncology
Department of Hematology-Oncology
UCSF Benioff Children's Hospital Oakland
Oakland, California

Amy G. Filbrun, MD, MS

Associate Professor of Pediatrics
Department of Pediatrics, Pulmonary Division
University of Michigan
Attending Faculty
Pediatrics
C.S. Mott Children's Hospital
Ann Arbor, Michigan

Anna B. Fishbein, MD, MS

Assistant Professor
Department of Pediatrics
Northwestern University
Division of Allergy & Immunology
Ann & Robert H. Lurie Children's Hospital of Chicago
Chicago, Illinois

Michael J. Fisher, MD

Associate Professor
Department of Pediatrics
Perelman School of Medicine at the University of Pennsylvania
Attending Physician
Division of Oncology

The Children's Hospital of Philadelphia
Philadelphia, Pennsylvania

Laurie N. Fishman, MD

Assistant Professor
Department of Pediatrics
Harvard Medical School
Director of Medical Education
Department of Pediatric Gastroenterology
Boston Children's Hospital
Boston, Massachusetts

Jonathan Fleenor, MD

Assistant Professor
Department of Pediatrics
Eastern Virginia Medical School
Pediatric Cardiologist
Cardiology
Children's Hospital of King's Daughters
Norfolk, Virginia

Leah Fleming, MD

Medical Genetics Fellow
National Human Genome Research Institute
National Institutes of Health
Bethesda, Maryland

Jay Fong, MD

Assistant Professor of Pediatrics
Department of Pediatrics
University of Massachusetts Medical School
UMass Memorial Medical Center
Boston, Massachusetts

Michelle Forcier, MD, MPH

Associate Professor, Clinical

Department of Pediatrics
The Warren Alpert Medical School of Brown University
Adolescent, Young Adult
Pediatrics
Hasbro Children's Hospital
Providence, Rhode Island

Craig M. Forester, MD, PhD

Fellow
Department of Pediatric Hematology/Oncology
University of California, San Francisco
San Francisco, California

Sara F. Forman, MD

Assistant Professor
Department of Pediatrics
Harvard Medical School
Clinical Director
Division of Adolescent/Young Adult Medicine
Boston Children's Hospital
Boston, Massachusetts

Karen R. Frattantoni, MD, MPH

Children's National Medical Center
Washington, DC

Melissa B. Freizinger, PhD

Instructor
Department of Psychiatry
Harvard Medical School
Associate Director, Eating Order Program
Adolescent Medicine
Boston Children's Hospital
Boston, Massachusetts

Ilona Frieden, MD

Professor
Department of Dermatology
University of California, San Francisco
Chief, Pediatric Dermatology
Vice-Chair, Department of Dermatology
University of California, San Francisco
San Francisco, California

Joel Aaron Friedlander, DO, MA

Assistant Professor
Departments of Pediatrics, Pediatric Gastroenterology
University of Colorado School of Medicine
Assistant Professor
Digestive Health Institute
Children's Hospital Colorado
Aurora, Colorado

Linda Fu, MD, MS

Assistant Professor of Pediatrics
Department of Pediatrics
The George Washington University
Pediatrician
Department of Pediatrics
Children's National Medical Center
Washington, DC

Ramsay L. Fuleihan, MD

Associate Professor of Pediatrics
Division of Allergy & Immunology
Department of Pediatrics
Northwestern University Feinberg School of Medicine
Attending Physician
Division of Allergy & Immunology
Department of Pediatrics
Ann & Robert H. Lurie Children's Hospital of Chicago
Chicago, Illinois

Nora M. Fullington, MD

Resident

Department of Surgery

University of Massachusetts Medical School

UMass Memorial Medical Center

Worcester, Massachusetts

John S. Fuqua, MD

Professor of Clinical Pediatrics

Section of Pediatric Endocrinology

Indiana University School of Medicine

Riley Hospital for Children at Indiana University Health

Indianapolis, Indiana

Susan L. Furth, MD, PhD

Professor

Departments of Pediatrics & Epidemiology

Perelman School of Medicine at the University of Pennsylvania

Chief, Division of Nephrology

Pediatrics

The Children's Hospital of Philadelphia

Philadelphia, Pennsylvania

Payal K. Gala, MD

Assistant Professor of Clinical Pediatrics

Department of Pediatrics

Perelman School of Medicine at the University of Pennsylvania

Attending Physician

Division of Emergency Medicine

The Children's Hospital of Philadelphia

Philadelphia, Pennsylvania

Theodore J. Ganley, MD

Associate Professor of Orthopaedic Surgery

Division of Orthopaedic Surgery

The Children's Hospital of Philadelphia

Philadelphia, Pennsylvania

Matthew Grady, MD

Assistant Professor

Department of Pediatrics

University of Pennsylvania School of Medicine

Primary Core Sports Medicine Fellowship Director

Department of Surgery, Division of Orthopedic

The Children's Hospital of Philadelphia

Philadelphia, Pennsylvania

George D. Gantsoudes, MD

Assistant Clinical Professor

Orthopaedic Surgery

Indiana University School of Medicine

Riley Hospital for Children at Indiana University Health

Indianapolis, Indiana

Ana Catarina Garnecho, MD

Pediatrician

Children's Hospital of Rhode Island

Pawtucket, Rhode Island

Jackie P-D. Garrett, MD

Attending Physician

Pediatrics

University of Pennsylvania

Attending Physician

Allergy and Immunology

Children's Hospital of Philadelphia

Philadelphia, Pennsylvania

Estelle B. Gauda, MD

Professor

Department of Pediatrics

Division of Neonatology

The Johns Hopkins University School of Medicine
Baltimore, Maryland

John P. Gearhart, MD

Robert D. Jeffs Professor of Pediatric Urology
The Johns Hopkins University School of Medicine
Director of Pediatric Urology
The Johns Hopkins Hospital
Baltimore, Maryland

Jeffrey S. Gerber, MD, PhD, MSCE

Assistant Professor of Pediatrics
Department of Pediatrics
The Children's Hospital of Philadelphia
Philadelphia, Pennsylvania

Saskia Gex, MD

Senior Clinical Associate
Chief Resident
Department of Pediatrics
New York-Presbyterian/Weill Cornell
New York, New York

Maureen M. Gilmore, MD

Assistant Professor
Department of Pediatrics
The Johns Hopkins University School of Medicine
Director of Neonatology
Pediatrics
Johns Hopkins Bayview Medical Center
Baltimore, Maryland

Janet Gingold, MD, MPH

Quality Improvement Coach
Goldberg Center for Community Pediatric Health
Children's National Medical Center

Washington, DC

Nicole S. Glaser, MD

Professor

Department of Pediatrics

University of California, Davis School of Medicine

Sacramento, California

Jenifer A. Glatz, MD

Assistant Professor

Department of Pediatrics

Dartmouth College

Lebanon, New Hampshire

Active Clinical Staff

Department of Pediatrics

Mary Hitchcock Memorial Hospital

Manchester, New Hampshire

W. Christopher Golden, MD

Assistant Professor of Pediatrics

Eudowood Neonatal Pulmonary Division

The Johns Hopkins University School of Medicine

Neonatologist and Medical Director

Full-Term Nursery

The Johns Hopkins Hospital

Baltimore, Maryland

Samuel B. Goldfarb, MD

Associate Professor of Clinical Pediatrics

Department of Pediatrics

University of Pennsylvania

Medical Director, Lung and Heart/Lung Transplant Programs

Department of Pediatrics

The Children's Hospital of Philadelphia

Philadelphia, Pennsylvania

Mitchell A. Goldstein, MD, MBA

Assistant Professor
Department of Pediatrics
The Johns Hopkins University School of Medicine
Child Protection Team Medical Director
Department of Pediatrics
Johns Hopkins Children's Center
Baltimore, Maryland

Stuart Goldstein, MD

Professor
Department of Pediatrics
University of Cincinnati College of Medicine
Director
Center for Acute Care Nephrology
Cincinnati Children's Hospital Medical Center
Cincinnati, Ohio

Esteban I. Gomez, MD

Hematology/Oncology Fellow
UCSF Benioff Children's Hospital - Oakland
Oakland, California

Blanca E. Gonzalez, MD

Assistant Professor
Center for Pediatric Infectious Diseases
Cleveland Clinic Lerner College of Medicine of Case Western University
Cleveland Clinic Children's Hospital
Cleveland, Ohio

Zoe M. Gonzalez-Garcia, MD

Pediatric Endocrinology Fellow
Department of Endocrinology
Phoenix Children's Hospital
Phoenix, Arizona

Vani V. Gopalareddy, MD

Associate Professor
Division of Pediatric GI/Hepatology
Department of Pediatrics
Levine Children's Hospital
Charlotte, North Carolina

Marc H. Gorelick, MD, MSCE

President and CEO, Children's Specialty Group
Professor of Pediatrics, Emergency Medicine
Sr. Associate Dean for Clinical Affairs (CSG)
Executive VP, Children's Hospital and Health System
The Medical College of Wisconsin
Children's Specialty Group, Children's Corporate Center
Milwaukee, Wisconsin

Jayaprakash A. Gosalakal, MD

Pediatrician
Children's Medical Center
St. Rita's Medical Center
Dayton, Ohio

Craig H. Gosdin, MD, MSHA

Assistant Professor of Pediatrics
Hospital Medicine
Cincinnati Children's Hospital Medical Center
Cincinnati, Ohio

Swathi Gowtham, MD

Pediatric Infectious Disease Specialist
Geisinger Health System
Janet Weis Children's Hospital
Danville, Pennsylvania

Rose C. Graham, MD, MSCE

Pediatric Gastroenterology

Durham, North Carolina

Cori Green, MD, MSc

Assistant Professor
General Academic Pediatrics
Weill Cornell Medical College
New York-Presbyterian
New York, New York

Adda Grimberg, MD

Associate Professor
Department of Pediatrics
Perelman School of Medicine at the University of Pennsylvania
Scientific Director
Diagnostic and Research Growth Center
The Children's Hospital of Philadelphia
Philadelphia, Pennsylvania

Andrew B. Grossman, MD

Assistant Professor of Clinical Pediatrics
Perelman School of Medicine at the University of Pennsylvania
Attending Physician
Co-Director, Center for Pediatric Inflammatory Bowel Disease
The Children's Hospital of Philadelphia
Philadelphia, Pennsylvania

Amit S. Grover, MD

Clinical Fellow in Pediatrics
Department of Pediatrics
Harvard Medical School
Boston Children's Hospital
Boston, Massachusetts

Roberto Gugig, MD

Gastroenterologist
Department of Gastroenterology

Valley Children's Hospital
Madera, California

Deepti Gupta, MD

Pediatric Dermatology Fellow
Department of Dermatology
University of California, San Francisco
San Francisco, California

Natasha Gupta, BS

Medical Student
Department of Pediatrics
The Johns Hopkins University School of Medicine
Baltimore, Maryland

Blaze Robert Gusic, MD

Pediatrician
West Chester, Pennsylvania

Kathleen Gutierrez, MD

Associate Professor
Pediatrics
Stanford University School of Medicine
Physician
Pediatrics-Infectious Disease
Lucile Packard Children's Hospital, Stanford University Hospital
Stanford, California

Maha N. Haddad, MD

Director of Pediatric Dialysis
Associate Professor
Pediatric Nephrologist
UC Davis Medical Center
University of California, Davis
Sacramento, California

Elizabeth J. Hait, MD, MPH

Instructor
Department of Pediatrics
Harvard Medical School
Attending Physician
Department of Gastroenterology and Nutrition
Boston Children's Hospital
Boston, Massachusetts

Chad R. Haldeman-Englert, MD

Assistant Professor
Department of Pediatrics-Genetics
Wake Forest School of Medicine
Winston-Salem, North Carolina

Mark E. Halstead, MD

Assistant Professor
Pediatrics and Orthopedics
Washington University School of Medicine
Assistant Professor
Pediatrics and Orthopedics
St. Louis Children's Hospital
St. Louis, Missouri

J. Nina Ham, MD

Assistant Professor
Department of Pediatrics
Emory University
Children's Healthcare of Atlanta
Atlanta, Georgia

Ada Hamosh, MD, MPH

Professor
Department of Pediatrics
McKusick-Nathans Institute of Genetic Medicine
Professor
Department of Epidemiology, Bloomberg School of Public Health

The Johns Hopkins University School of Medicine
Baltimore, Maryland

Brian D. Hanna, MD, PhD

Clinical Professor of Pediatrics
University of Pennsylvania School of Medicine
Director, Section of Pulmonary Hypertension
The Children's Hospital of Philadelphia
Philadelphia, Pennsylvania

Zeev Harel, MD

Pediatrician
Division of Adolescent Medicine
Hasbro Children's Hospital
Providence, Rhode Island

Daphne M. Hasbani, MD, PhD

Clinical Neurophysiology and Epilepsy Fellow
Division of Neurology, Department of Pediatrics
The Children's Hospital of Philadelphia
Philadelphia, Pennsylvania

Caroline Hastings, MD

Fellowship Director
Pediatric Hematology/Oncology
Children's Hospital and Research Center Oakland
Oakland, California

Sarah Z. Hatab, MD

Pediatric Endocrinology Fellow
Department of Pediatric, Division of Endocrinology & Metabolism
Emory University School of Medicine
Children's Healthcare of Atlanta
Atlanta, Georgia

David Hehir, MD, MS

Associate Professor

Department of Pediatrics
Sidney Kimmel Medical College of Thomas Jefferson University
Philadelphia, Pennsylvania
Chief
Division of Cardiac Critical Care
Nemours Alfred I. duPont Hospital for Children
Wilmington, Delaware

Mayada A. Helal, MD

Fellow
Department of Pediatrics
The Hospital for Sick Children
Toronto, Ontario, Canada

Michelle L. Hermiston, MD, PhD

Associate Professor
Department of Pediatrics
University of California, San Francisco
UCSF Benioff Children's Hospital San Francisco
San Francisco, California

Eugene R. Hershorin, MD

Professor
Department of Pediatrics
University of Miami Miller School of Medicine
Miami, Florida

Kathryn Hillenbrand, MD, CCC-SLP

Master Clinical Specialist
Department of Speech Pathology and Audiology
Western Michigan University
Kalamazoo, Michigan

Bernadette A. Hillman, MD

Assistant Professor
Department of Pediatrics

University of Connecticut
Farmington, Connecticut
Attending Clinical Instructor
Department of Pediatrics
Yale University
New Haven, Connecticut
Neonatologist
Department of Pediatrics
The Hospital of Central Connecticut
New Britain, Connecticut

Tanya Hinds, MD, MS, FAAP

Assistant Professor
Department of Pediatrics
The George Washington University
Child Abuse Pediatrician
Child and Adolescent Protection Center
Children's National Medical Center
Washington, DC

Gurumurthy Hiremath, MD, MBBS

Pediatric Cardiology Fellow
Department of Pediatrics
University of California, San Francisco
UCSF Benioff Children's Hospital San Francisco
San Francisco, California

Michael P. Hirsh, MD

Professor of Surgery and Pediatrics
University of Massachusetts Medical School
Associate Director
Pediatric Intensive Care Unit
Worcester, Massachusetts

Hiwot Hiruy, MD

Postdoctoral Fellow

Department of Pediatrics
The Johns Hopkins University School of Medicine
Postdoctoral Fellow
Department of Pediatrics
The Johns Hopkins Hospital
Baltimore, Maryland

Adam B. Hittelman, MD, PhD

Assistant Professor
Department of Urology
Yale School of Medicine
Pediatric Urology
Department of Urology
Yale–New Haven Hospital
New Haven, Connecticut

Janice E. Hobbs, MD, MPH

Postdoctoral Fellow
Department of Pediatrics
The Johns Hopkins University School of Medicine
Neonatology Fellow
Pediatrics
The Johns Hopkins Hospital
Baltimore, Maryland

Robert J. Hoffman, MD, MS

Director, Clinical Toxicology
Emergency Medicine
Sidra Medical and Research Center
Doha, Qatar

Paul Hofman, MD

Professor Pediatric Endocrinology
Liggins Institute
University of Auckland
Auckland, New Zealand

David K. Hong, MD

Clinical Assistant Professor, Pediatrics-Infectious Disease
Department of Pediatrics
Stanford University
Palo Alto, California

Stefany B. Honigbaum, MD

Pediatric Gastroenterology and Nutrition Fellow
Department of Pediatrics
The Johns Hopkins University School of Medicine
Division of Pediatric Gastroenterology and Nutrition
Johns Hopkins Children's Center
Baltimore, Maryland

Biljana N. Horn, MD

Clinical Professor
Medical Director Pediatric BMT
Department of Pediatrics
UCSF Benioff Children's Hospital San Francisco
San Francisco, California

Arvind Hoskoppal, MD, MHS

Assistant Professor of Pediatrics and Internal Medicine
University of Utah
Salt Lake City, Utah

Renee Howard, MD

Associate Professor
Department of Dermatology
University of California, San Francisco
San Francisco, California

Jessica Howlett, MD

Neonatologist
Sunflower Neonatology Associates
Overland Park, Kansas

Michael H. Hsieh, MD, PhD

Assistant Professor
Department of Urology
Stanford University School of Medicine
Lucile Packard Children's Hospital Stanford
Stanford, California

Benjamin J. Huang, MD

Clinical Fellow
Department of Pediatrics
Division of Hematology/Oncology
University of California, San Francisco
Clinical Fellow
Department of Pediatrics
Division of Hematology/Oncology
UCSF Benioff Children's Hospital San Francisco
San Francisco, California

James N. Huang, MD

Professor
Department of Pediatrics
University of California, San Francisco
Director of Hematology
Department of Pediatrics
UCSF Benioff Children's Hospital San Francisco
San Francisco, California

Tannie Huang, MD

Assistant Adjunct Professor
Department of Pediatric Hematology Oncology
University of California, San Francisco
San Francisco, California

Jennifer Huffman, MD

Pediatric Neurologist
Department of Pediatrics

Randall Children's Hospital
Portland, Oregon

Erik A. Imel, MD

Assistant Professor of Medicine and Pediatrics
Department of Medicine & Department of Pediatrics
Indiana University School of Medicine
Department of Pediatrics, Section of Pediatric Endocrinology
Riley Hospital for Children at Indiana University Health
Indianapolis, Indiana

Allison M. Jackson, MD, MPH, FAAP

Associate Professor of Pediatrics
School of Medicine and Health Sciences
The George Washington University
Division Chief
The Freddie Mac Foundation Child and Adolescent Protection Center
Children's National Medical Center
Washington, DC

Oksana A. Jackson, MD

Assistant Professor
Division of Plastic Surgery
Perelman School of Medicine at the University of Pennsylvania
Attending Surgeon
Division of Plastic Surgery
The Children's Hospital of Philadelphia
Philadelphia, Pennsylvania

Shonul A. Jain, MD

Assistant Professor
Department of Pediatrics
University of California, San Francisco
Medical Director, Children's Health Center
Department of Pediatrics
San Francisco General Hospital

San Francisco, California

John L. Jefferies, MD, MPH, FACC

Associate Professor, Pediatric Cardiology and Adult Cardiovascular
Diseases

The Heart Institute

Director, Advanced Heart Failure

Pediatrics

Cincinnati Children's Hospital Medical Center

Cincinnati, Ohio

Karen E. Jerardi, MD, MEd

Assistant Professor

Department of Pediatrics

University of Cincinnati School of Medicine

Attending Physician

Division of Hospital Medicine

Cincinnati Children's Hospital Medical Center

Cincinnati, Ohio

Chandy C. John, MD, MS

Professor

Departments of Pediatrics and Medicine

University of Minnesota

Director, Division of Global Pediatrics

Department of Pediatrics

University of Minnesota Amplatz Children's Hospital

Minneapolis, Minnesota

Ray J. Jurado, DDS

Pediatric Dentist

Ann & Robert H. Lurie Children's Hospital of Chicago

Chicago, Illinois

Dylan Kann, MD

Clinical Fellow

Department of Pediatrics
Stanford University School of Medicine
Clinical Fellow
Department of Pediatric Infectious Diseases
Lucile Packard Children's Hospital Stanford
Stanford, California

Chirag R. Kapadia, MD

Clinical Assistant Professor
Department of Pediatrics
University of Arizona College of Medicine Phoenix
Faculty
Endocrinology
Phoenix Children's Hospital
Phoenix, Arizona

Robert D. Karch, MD, MPH

Department of Surgery

University of Maryland School of Medicine
Baltimore, Maryland

Sarah S. Lusman, MD, PhD

Assistant Professor of Pediatrics
Departments of Pediatric Gastroenterology, Hepatology and Nutrition
Columbia University Medical Center
Assistant Attending Pediatrician
Pediatric Gastroenterology, Hepatology and Nutrition
Morgan Stanley Children's Hospital of New York-Presbyterian
New York, New York

Minnelly Luu, MD

Assistant Professor of Dermatology
Department of Dermatology
University of Southern California
Children's Hospital Los Angeles
Los Angeles, California

Ngoc P. Ly, MD, MPH

Associate Professor
Department of Pediatrics
University of California, San Francisco
Pediatric Pulmonologist
Pediatrics
UCSF Benioff Children's Hospital San Francisco
San Francisco, California

Brian M. Inouye, MD

Department of Urology
Division of Pediatric Urology
The Johns Hopkins University School of Medicine
The Johns Hopkins Hospital
Baltimore, Maryland

Sheela N. Magge, MD, MSCE

Assistant Professor of Pediatrics
Department of Pediatrics
The Children's Hospital of Philadelphia
Philadelphia, Pennsylvania

Melanie M. Makhija, MD, MS

Assistant Professor of Pediatrics
Pediatrics
Northwestern University Feinberg School of Medicine
Attending Physician
Allergy & Immunology
Ann & Robert H Lurie Children's Hospital of Chicago
Chicago, Illinois

Michael A. Manfredi, MD

Instructor in Pediatrics
Harvard Medical School
Associate Director, Esophageal Atresia Treatment Program
Associate Director, Gastrointestinal Procedure Unit
Attending Physician
Division of Gastroenterology, Hepatology & Nutrition
Boston Children's Hospital
Boston, Massachusetts

Melissa L. Mannion, MD

Fellow, Pediatric Rheumatology
Department of Pediatrics
University of Alabama at Birmingham
Birmingham, Alabama

Bradley S. Marino, MD, MPP, MSCE

Associate Professor of Pediatrics
Department of Pediatrics
University of Cincinnati College of Medicine
Director, Heart Institute Research Core
Attending Cardiac Intensivist, Cardiac Intensive Care Unit

Divisions of Cardiology and Critical Care Medicine
Cincinnati Children's Hospital Medical Center
Cincinnati, Ohio

Fiona Marion, MB, BCh, BAO

Fellow

Division of Pediatric Pulmonary Medicine
UCSF Benioff Children's Hospital San Francisco
San Francisco, California

Jennifer A. Markowitz, MD

Instructor in Neurology
Department of Pediatric Neurology
Harvard Medical School
Attending in Neurology
Department of Pediatric Neurology
Boston Children's Hospital
Boston, Massachusetts

Andrea Marmor, MD

Associate Professor, Pediatrics
Department of Pediatrics
University of California, San Francisco
San Francisco General Hospital
San Francisco, California

Renée Marquardt, MD

Child & Adolescent Psychiatry
University of California, San Francisco
San Francisco, California

Anne M. Marsh, MD

Associate Hematologist-Oncologist
Department of Pediatric Hematology & Oncology
Children's Hospital & Research Center Oakland
Oakland, California

Holly H. Martin, MD

Assistant Professor
Department of Pediatrics
University of California, San Francisco
San Francisco, California

Zankhana Master, MD

Neonatology Fellow
Department of Pediatrics, Division of Neonatology
The Johns Hopkins University School of Medicine
Baltimore, Maryland

Lucy D. Mastrandrea

Assistant Professor
Department of Pediatrics
University at Buffalo, School of Medicine and Biomedical Sciences
Physician
Division of Pediatric Endocrinology
Women and Children's Hospital of Buffalo
Buffalo, New York

Erin Mathes, MD

Assistant Professor of Dermatology and Pediatrics
Department of Dermatology
University of California, San Francisco
San Francisco, California

Carol A. Mathews, MD

Langley Porter Psychiatric Institute
Associate Professor
Department of Psychiatry
University of California, San Francisco
San Francisco, California

Anubhav Mathur, MD, PhD

Assistant Clinical Professor

Department of Dermatology
University of California, San Francisco
UCSF Benioff Children's Hospital San Francisco
San Francisco, California

Alison T. Matsunaga, MD

Assistant Clinical Instructor
Department of Pediatric Hematology Oncology
University of California, San Francisco
Hematologist/Oncologist
Department of Hematology Oncology
Children's Hospital and Research Institute Oakland
Oakland, California

Oscar H. Mayer, MD

Associate Professor of Clinical Pediatrics
Department of Pediatrics
Perelman School of Medicine at the University of Pennsylvania
Division of Pulmonary Medicine
The Children's Hospital of Philadelphia
Philadelphia, Pennsylvania

Angela Mazur, MD

Department of Pediatric Medicine, Academic Medicine
Texas Children's Hospital
Houston, Texas

Donna M. McDonald-McGinn, MS, CGC

Division of Human Genetics
The Children's Hospital of Philadelphia
Philadelphia, Pennsylvania

Scott McKay, MD

Assistant Professor of Orthopedics
Baylor College of Medicine
Attending Physician

Department of Surgery, Orthopedics
Texas Children's Hospital
Houston, Texas

Tracey A. McLean, MD

Clinical Instructor
Departments of Obstetrics, Gynecology and Reproductive Sciences
University of California, San Francisco
San Francisco, California

Maureen C. McMahon, MD

Assistant Professor
Department of Pediatrics
Jefferson Medical College
Philadelphia, Pennsylvania
General Pediatrician
General Pediatrics
Nemours duPont Pediatrics, Lankenau
Wynnewood, Pennsylvania

Margaret M. McNamara, MD

Associate Clinical Professor of Pediatrics
Department of Pediatrics
Director of Preceptor Outreach, UCSF Office of Medical Education
Co-Director Foundations of Patient Care
University of California, San Francisco
San Francisco, California

Maireade E. McSweeney, MD, MPH

Instructor
Harvard Medical School
Attending Physician
Division of Gastroenterology, Hepatology & Nutrition
Boston Children's Hospital
Boston, Massachusetts

Heather L. Meluskey, CRNP-AC

Pediatric Nurse Practitioner
Section of Pulmonary Hypertension
Division of Cardiology
The Children's Hospital of Philadelphia
Philadelphia, Pennsylvania

Shina Menon, MD

Fellow
Center for Acute Care Nephrology
Cincinnati Children's Hospital Medical Center
Cincinnati, Ohio

Jondavid Menteer, MD

Assistant Professor
Department of Pediatrics
Keck School of Medicine of USC
Director
Heart Failure Program
Division of Cardiology
Children's Hospital Los Angeles
Los Angeles, California

Laura Mercer-Rosa, MD, MSCE

Assistant Professor
Department Pediatrics
University of Pennsylvania
Cardiologist
Pediatrics
The Children's Hospital of Philadelphia
Philadelphia, Pennsylvania

Dan Merenstein, MD

Director, Research Division
Georgetown University Medical Center
Washington, DC

Caitlin Messner, MD

Pediatrician

Cleveland, Ohio

Michele Mietus-Snyder, MD

Associate Professor

Department of Pediatrics

The George Washington University

Co-Director Children's National Obesity Institute

Department of Cardiology

Children's National Health System

Washington, DC

Jane E. Minturn, MD, PhD

Assistant Professor

Department of Pediatrics

Perelman School of Medicine at the University of Pennsylvania

Attending Physician

Division of Oncology

The Children's Hospital of Philadelphia

Philadelphia, Pennsylvania

Hussnain S. Mirza, MD

Assistant Professor

Pediatrics

University of Central Florida College of Medicine

Attending Neonatologist

Neonatal ICU/Pediatrics

Florida Hospital for Children

Orlando, Florida

Nazrat Mirza, MD, ScD

Associate Professor

Department of General Pediatrics and Adolescent Medicine

The George Washington University

Attending Physician

General Pediatrics and Adolescent Medicine
Children's National Medical Center
Washington, DC

Douglas B. Mogul, MD, MPH

Assistant Professor
Department of Pediatrics
The Johns Hopkins University School of Medicine
Baltimore, Maryland

Angela P. Mojica, MD

Pediatric Endocrinologist
Department of Pediatrics
Marshfield Clinic
Marshfield, Wisconsin

Kimberly Molina, MD

Assistant Professor
Department of Pediatrics
University of Utah
Salt Lake City, Utah

Bradley J. Monash, MD

Assistant Clinical Professor
Department of Medicine
Academic Hospitalist
Department of Medicine and Pediatrics
University of California, San Francisco
San Francisco, California

Rachel Moon, MD

Professor
Department of Pediatrics
The George Washington University School of Medicine & Health
Sciences
Director of Academic Development

Goldberg Center for Community Pediatric Health
Children's National Medical Center
Washington, DC

Craig Munns, MBBS, PhD, FRACP

Associate Professor
Department of Pediatrics and Child Health
University of Sydney
Senior Staff Specialist
Department of Endocrinology and Diabetes
The Children's Hospital at Westmead
Sydney, Australia

Krupa R. Mysore, MD

Fellow
Division of Pediatric Gastroenterology and Hepatology
Texas Children's Hospital
Baylor College of Medicine
Houston, Texas

John R. Mytinger, MD

Assistant Professor
Department of Pediatrics
Division of Pediatric Neurology
Ohio State University
Nationwide Children's Hospital
Columbus, Ohio

Zeina M. Nabhan, MD

Associate Professor of Clinical Pediatrics
Department of Pediatric Endocrinology
Indiana University School of Medicine
Associate Professor
Department of Pediatrics
Riley Hospital for Children at Indiana University Health
Indianapolis, Indiana

Frances M. Nadel, MD, MSCE

Professor of Clinic Pediatrics

Department of Pediatrics

Perelman School of Medicine at the University of Pennsylvania

Attending Physician

Division of Emergency Medicine

Children's Hospital of Philadelphia

Philadelphia, Pennsylvania

Jessica Rose Nance, MD, MS

Assistant Professor

Department of Neurology

The Johns Hopkins University School of Medicine

The Johns Hopkins Hospital

Baltimore, Maryland

Jessica Nash, MD

Associate Professor

Department of Pediatrics

The George Washington University

General Pediatrics & Community Health

Children's National Medical Center

Washington, DC

Luz Natal-Hernandez, MD

Pediatric Cardiologist

Pediatric Specialties

Roseville Medical Center

Roseville, California

Avindra Nath, MD

Clinical Director

National Institute of Neurological Disorders and Stroke

National Institutes of Health

Bethesda, Maryland

Pradeep P. Nazarey, MD

Assistant Professor of Surgery
University of Massachusetts Medical School
UMass Memorial Medical Center
Boston, Massachusetts

Kelly L. Neale, RN, MS, CPNP

Pediatric Nurse Practitioner
Department of Pediatric Oncology/Hematology
University of California, San Francisco
San Francisco, California

Todd D. Nebesio, MD

Associate Professor of Clinical Pediatrics
Department of Pediatrics
Indiana University School of Medicine
Riley Hospital for Children at Indiana University Health
Indianapolis, Indiana

Bettina Neumann, PT, LLCC

Consultant
Department of Rehab Services
University of San Francisco
Physical Therapist, CEO
Outpatient Physical Therapy in Private Practice
Rising Sun Physical Therapy
San Francisco, California

Jason Newland, MD, MEd

Associate Professor
Department of Pediatrics
University of Missouri-Kansas City School of Medicine
Faculty
Department of Pediatrics
The Children's Mercy Hospital
Kansas City, Missouri

Jessica Newman, DO

Assistant Professor
Division of Infectious Diseases, Department of Internal Medicine
University of Kansas Medical Center
Kansas City, Kansas

Ross Newman, DO

Associate Program Director, Pediatrics
University of Missouri-Kansas City School of Medicine
Kansas City, Missouri

Peter D. Ngo, MD

Attending Gastroenterologist
Division of Gastroenterology, Hepatology & Nutrition
Boston Children's Hospital
Boston, Massachusetts

Stephanie Nguyen, MD, MAS

Assistant Professor
Department of Pediatrics
Division of Nephrology
University of California, Davis
Assistant Professor
Department of Pediatrics
UC Davis Medical Center
Sacramento, California

Julie M. Noguee, MD

Associate Physician
Department of Pediatrics
University of California, San Francisco
San Francisco, California

Lawrence M. Noguee, MD

Professor
Department of Pediatrics, Eudowood Neonatal Respiratory Division

The Johns Hopkins University School of Medicine
Attending Neonatologist
Department of Pediatrics
Johns Hopkins Children's Center
Baltimore, Maryland

Frances J. Northington, MD

Professor of Neonatal-Perinatal Medicine
The Johns Hopkins University School of Medicine
Department of Pediatrics
Johns Hopkins Children's Center
Baltimore, Maryland

D. David O'Banion, MD

Fellow in Developmental-Behavioral Pediatrics
Department of Pediatrics
University of Oklahoma Health Sciences Center
Oklahoma City, Oklahoma

Christopher B. Oakley, MD

Assistant Professor-Clinical Educator
Neurology
The Johns Hopkins University School of Medicine
The Johns Hopkins Hospital
Baltimore, Maryland

Julie O'Brien, MD, MS

Assistant Clinical Professor
Department of Pediatrics
University of California, San Francisco
San Francisco, California

Heather Olson, MD

Fellow in Epilepsy/Neurogenetics
Department of Neurology, Division of Epilepsy and Clinical
Neurophysiology

Boston Children's Hospital
Boston, Massachusetts

Kent Olson, MD

Clinical Professor, Medicine & Pharmacy
University of California, San Francisco
Medical Director
San Francisco Division
California Poison Control System
Department of Clinical Pharmacy
University of California, San Francisco
San Francisco, California

Oluwakemi B. Badaki-Makun, MD, CM

Assistant Professor
Department of Pediatrics
The Johns Hopkins University School of Medicine
Attending Physician
Division of Pediatric Emergency Medicine
Johns Hopkins Children's Center
Baltimore, Maryland

Bruce A. Ong, MD, MPH

Pediatric Pulmonologist
Department of Pediatrics
Tripler Army Medical Center
Honolulu, Hawaii

Anna E. Ordóñez, MD

Assistant Professor
Department of Psychiatry
University of California, San Francisco
Medical Director
Infant Child and Adolescent Psychiatry
Department of Psychiatry
San Francisco General Hospital

San Francisco, California

Kevin C. Osterhoudt, MD, MS

Professor

Department of Pediatrics

Perelman School of Medicine at the University of Pennsylvania

Medical Director

The Poison Control Center

The Children's Hospital of Philadelphia

Philadelphia, Pennsylvania

Mary Ottolini, MPH

Professor of Pediatrics

Pediatrics

The George Washington University School of Medicine & Health
Sciences

Vice-Chair of Education

Designated Institutional Official

Children's National Medical Center

Washington, DC

Vikash S. Oza, MD

Fellow

Department of Pediatric Dermatology

University of California, San Francisco

San Francisco, California

Erica S. Pan, MD, MPH, FAAP

Associate Clinical Professor

Department of Pediatrics, Division of Infectious Diseases

University of California, San Francisco

San Francisco, California

Deputy Health Officer

Director

Division of Communicable Disease Control & Prevention

Alameda County Public Health Department

Oakland, California

Rita Panoscha, MD

Pediatrician

Oregon Health & Sciences University

Portland, Oregon

Helen Pappa, MD

Assistant Professor of Pediatrics

Cardinal Glennon Children's Medical Center

St. Louis, Missouri

Carolyn A. Paris, MD

Associate Professor

Department of Emergency Medicine

Seattle Children's Hospital

Seattle, Washington

Hee-Jung Park, MD, MPH

Pediatric Ophthalmologist

Virginia Mason Hospital and Seattle Medical Center

Seattle, Washington

Kristen L. Park, MD

Assistant Professor

Departments of Pediatrics and Neurology

University of Colorado

Division of Pediatric Neurology

Children's Hospital Colorado

Aurora, Colorado

Michelle W. Parker, MD

Assistant Professor

University of Cincinnati Department of Pediatrics

Attending Physician

Division of Hospital Medicine

Cincinnati, Ohio

Kiran Patel, MD, MS

Allergy & Immunology Fellow
Department of Pediatrics
University of California, San Francisco
San Francisco Medical Center
San Francisco, California

Irina Pateva, MD

Fellow
Department of Pediatrics
Case Western Reserve University
Fellow
Division of Pediatrics Hematology/Oncology
Rainbow Babies & Children's Hospital
Cleveland, Ohio

Barry Pelz, MD

Allergy-Immunology Fellow
Northwestern University Feinberg School of Medicine
Chicago, Illinois

Elena Elizabeth Perez, MD, PhD

Associate Professor
Department of Pediatrics
University of Miami
Associate Professor
Department of Pediatrics
University of Miami, Jackson Memorial Hospital
Miami, Florida

Farzana Perwad, MD

Assistant Adjunct Professor of Pediatrics
University of California, San Francisco
Department of Nephrology
UCSF Benioff Children's Hospital San Francisco
San Francisco, California

Christopher Petit, MD

Assistant Professor of Pediatrics
Department of Pediatrics
Emory University School of Medicine
Attending Physician
Sibley Heart Center
Children's Healthcare of Atlanta
Atlanta, Georgia

Shabnam Peyvandi, MD

Assistant Professor of Clinical Pediatrics
Department of Pediatrics, Division of Cariology
University of California, San Francisco
UCSF Benioff Children's Hospital San Francisco
San Francisco, California

Joseph A. Picoraro, MD

Postdoctoral Fellow
Department of Pediatric Gastroenterology, Hepatology and Nutrition
Columbia University Medical Center
Morgan Stanley Children's Hospital of New York-Presbyterian
New York, New York

Nelangi Pinto, MD

Associate Professor
Division of Pediatric Cariology
Department of Pediatrics
University of Utah
Salt Lake City, Utah

Pisit Pitukcheewanont, MD

Assistant Professor of Clinical Pediatrics
Department of Pediatrics
Keck School of Medicine of USC
Los Angeles, California

Jonathan R. Pletcher, MD

Associate Professor
Department of Pediatrics
University of Pittsburgh School of Medicine
Clinical Director
Department of Adolescent Medicine
Children's Hospital of Pittsburgh of UPMC
Pittsburgh, Pennsylvania

Annapurna Poduri, MD, MPH

Assistant Professor
Department of Neurology
Harvard Medical School
Attending in Epilepsy
Director, Epilepsy Genetics
Department of Neurology
Boston Children's Hospital
Boston, Massachusetts

Charles A. Pohl, MD

Professor
Department of Pediatrics
Sidney Kimmel Medical Center
Department of Pediatrics
Thomas Jefferson University/Nemours
Philadelphia, Pennsylvania

Anthony A. Portale, MD

Professor in Residence, Pediatrics
Chief, Division of Pediatric Nephrology
Medical Director, Pediatric Renal Transplant Program
Program Director, Pediatric Nephrology Fellowship Training Program
Department of Pediatrics
University of California, San Francisco
San Francisco, California

Evelyn Porter, MD, MS

Assistant Professor

Departments of Emergency Medicine and Pediatrics

University of California, San Francisco

San Francisco, California

Jill C. Posner, MD, MSCE

Associate Professor of Clinical Practice

Department of Pediatrics, Division of Pediatric Emergency Medicine

Perelman School of Medicine at the University of Pennsylvania

Attending Physician

Department of Pediatrics, Division of Pediatric Emergency Medicine

The Children's Hospital of Philadelphia

Philadelphia, Pennsylvania

Madhura Pradhan, MD, DCH

Associate Professor of Clinical Pediatrics

Department of Pediatrics

Perelman School of Medicine at the University of Pennsylvania

The Children's Hospital of Philadelphia

Philadelphia, Pennsylvania

Victoria E. Price

Division of Hematology/Oncology

Department of Pediatrics

IWK Health Centre

Halifax, Nova Scotia, Canada

Benjamin T. Prince, MD

Fellow

Department of Pediatrics

Northwestern University Feinberg School of Medicine

Division of Allergy and Immunology

Ann & Robert H. Lurie Children's Hospital of Chicago

Chicago, Illinois

Manisha Punwani, MD

Director, Child and Adolescent Psychiatry Training
Associate Professor
Department of Psychiatry
University of California, San Francisco
San Francisco, California

Latika Puri, MD

Fellow
Pediatric Hematology/ Oncology
Children's Hospital and Research Center Oakland
Oakland, California

Katherine B. Püttgen, MD

Assistant Professor
Department of Dermatology, Division of Pediatric Dermatology
The Johns Hopkins University School of Medicine
Baltimore, Maryland

Nashmia Qamar, DO

Fellow
Department of Pediatrics, Division of Allergy & Immunology
Northwestern University Feinberg School of Medicine
Ann & Robert H. Lurie Children's Hospital of Chicago
Chicago, Illinois

Keith Quirolo, MD

Clinical Instructor
Department of Pediatrics
UCSF Benioff Children's Hospital San Francisco
San Francisco, California
Director, Apheresis
Hematology
UCSF Benioff Children's Hospital Oakland
Oakland, California

Christopher P. Raab, MD

Assistant Professor

Department of Pediatrics

Sidney Kimmel Medical College of Thomas Jefferson University

Philadelphia, Pennsylvania

Staff Pediatrician

Department of Pediatrics

Nemours Alfred I. duPont Hospital for Children

Wilmington, Delaware

Kacy A. Ramirez, MD

Assistant Professor

Department of Pediatrics

Wake Forest School of Medicine

Assistant Professor

Department of Pediatrics

Brenner Children's Hospital/Wake Forest Baptist Medical Center

Winston-Salem, North Carolina

Daniel Ranch, MD

Assistant Professor

Department of Pediatrics

University of Texas Health Science Center, San Antonio

San Antonio, Texas

Sergio E. Recuenco

Epidemiologist

NCEZID/HCPP/PRB/Rabies Program

U.S. Centers for Disease Control and Prevention

Atlanta, Georgia

Richard J. Redett, MD

Associate Professor

Department of Plastic and Reconstructive Surgery

The Johns Hopkins University School of Medicine

Baltimore, Maryland

Rebecca Reindel, MD

Pediatrician

Children's Memorial Hospital

Chicago, Illinois

Michael X. Repka, MD, MBA

Professor

Wilmer Eye Institute

The Johns Hopkins University School of Medicine

Active Staff

Wilmer Eye Institute

Baltimore, Maryland

David C. Rettew, MD

Associate Professor

Department of Psychiatry

Department of Pediatrics

The University of Vermont School of Medicine

Burlington, Vermont

Leah G. Reznick, MD

Assistant Professor

Department of Ophthalmology

Casey Eye Institute

Oregon Health & Sciences University

Portland, Oregon

Hope Rhodes, MD

General Pediatrician

Assistant Professor

Department of Pediatrics

The George Washington University School of Medicine & Health
Sciences

General Pediatrician

General and Community Pediatrics

Children's National Medical Center

Washington, DC

Alisson Richards, MD

Robert A. Garrett Professor of Pediatric Urologic Research

Professor

Indiana University School of Medicine

Department of Urology

Indianapolis, Indiana

Elizabeth Robbins, MD

Clinical Professor

Department of Pediatrics

University of California, San Francisco

Clinical Professor

Department of Pediatrics

UCSF Benioff Children's Hospital San Francisco

San Francisco, California

Laura Robertson, MD

Associate Clinical Professor

Department of Pediatrics

University of California, San Francisco

UCSF Benioff Children's Hospital San Francisco

San Francisco, California

Rachel G. Robison, MD

Assistant Professor

Department of Pediatrics

Northwestern University Feinberg School of Medicine

Attending Physician
Pediatrics, Division of Allergy & Immunology
Ann & Robert H. Lurie Children's Hospital of Chicago
Chicago, Illinois

Rohini Coorg, MD

Fellow, Pediatric Epilepsy
Department of Neurology
Washington University School of Medicine
St. Louis Children's Hospital
St. Louis, Missouri

Kristina W. Rosbe, MD, FAAP, FACS

Professor
Departments of Otolaryngology and Pediatrics
University of California, San Francisco
Chief of Pediatric Otolaryngology
UCSF Benioff Children's Hospital San Francisco
San Francisco, California

Rebecca Ruebner, MD, MSCE

Assistant Professor
Department of Pediatrics
University of Pennsylvania
Assistant Professor
Department of Pediatrics, Division of Nephrology
The Children's Hospital of Philadelphia
Philadelphia, Pennsylvania

Matthew J. Ryan, MD

Assistant Professor of Pediatrics
Department of Pediatrics
Perelman School of Medicine at the University of Pennsylvania
Attending Physician
Pediatrics
The Children's Hospital of Philadelphia

Philadelphia, Pennsylvania

Thomas G. Saba, MD

Fellow

Department of Pediatrics, Pulmonary Division

University of Michigan

C.S. Mott Children's Hospital

Ann Arbor, Michigan

Camille Sabella, MD

Associate Professor of Pediatrics

Vice-Chair for Education, Pediatric Institute

Director, Center for Pediatric Infectious Diseases

Cleveland Clinic Children's

Cleveland, Ohio

Sabina Sabharwal, MD, MPH

Instructor

Department of Pediatrics

Harvard Medical School

Attending Staff Physician

Department of Pediatric Gastroenterology and Nutrition

Boston Children's Hospital

Boston, Massachusetts

Amit J. Sabnis, MD

Instructor

Department of Hematology-Oncology

UCSF Benioff Children's Hospital San Francisco

San Francisco, California

Denise A. Salerno, MD

Professor of Clinical Pediatrics

Department of Pediatrics

Temple University School of Medicine

Philadelphia, Pennsylvania

Kara N. Saperston, MD

Pediatric Urology Clinical Fellow
Department of Urology
University of California, San Francisco
San Francisco, California

Julia Shaklee Sammons, MD, MSCE

Assistant Professor
Department of Pediatrics, Division of Infectious Diseases
Perelman School of Medicine at the University of Pennsylvania
Medical Director and Hospital Epidemiologist
Department of Infection Prevention and Control
The Children's Hospital of Philadelphia
Philadelphia, Pennsylvania

Pablo J. Sanchez, MD

Professor of Pediatrics
The Ohio State University College of Medicine
Director of Clinical and Translational Research in Neonatology
Nationwide Children's Hospital
Columbus, Ohio

Melissa T. Sanford, MD

Resident Physician
Department of Urology
University of California, San Francisco
San Francisco, California

Emily M. Schaaf, MD

Pediatric Infectious Disease Fellow
Department of Pediatric Infectious Disease
University of Minnesota Amplatz Children's Hospital
Minneapolis, Minnesota

Adrienne M. Scheich, MD

Health Systems Clinician

Department of Pediatrics
Northwestern University Feinberg School of Medicine
Attending Physician
Department of Pediatric Gastroenterology
Ann & Robert H. Lurie Children's Hospital of Chicago
Chicago, Illinois

Rebecca Schein, MD

Assistant Professor
Department of Pediatrics
Case Western Reserve University
Physician-Infectious Disease
Department of Pediatrics
MetroHealth Medical Center
Cleveland, Ohio

Angela Scheuerle, MD

Professor
Department of Pediatrics, Division of Genetics and Metabolism
University of Texas Southwestern Medical Center
Dallas, Texas

Jocelyn H. Schiller, MD

Associate Professor
Department of Pediatrics and Communicable Diseases
University of Michigan Medical School
Pediatric Hospitalist
Department of Pediatrics and Communicable diseases
University of Michigan Health System
Ann Arbor, Michigan

Amanda C. Schondelmeyer, MD

Division of Hospital Medicine
Cincinnati Children's Hospital Medical Center
Cincinnati, Ohio

Director, Pediatric Arrhythmia Service

UCSF Benioff Children's Hospital San Francisco

Department of Pediatrics

University of California, San Francisco

San Francisco, California

Carl Tapia, MD

Assistant Professor

Division of Pediatrics

Baylor College of Medicine

Houston, Texas

Anupama R. Tate, DMD, MHP

Associate Professor

Department of Pediatrics

The George Washington University School of Medicine & Health
Sciences

Director, Advocacy & Research

Division of Oral Care

Children's National Medical Center

Washington, DC

Danna Tauber, MD, MPH

Assistant Professor

Department of Pediatrics

Drexel University College of Medicine

Attending Physician

Section of Pulmonology

St. Christopher's Hospital for Children

Philadelphia, Pennsylvania

Jesse A. Taylor, MD

Assistant Professor

Department of Surgery

Perelman School of Medicine at the University of Pennsylvania

Plastic Surgeon

Department of Plastic Surgery

The Children's Hospital of Philadelphia

Philadelphia, Pennsylvania

David T. Teachey, MD

Assistant Professor

Department of Pediatrics

Perelman School of Medicine at the University of Pennsylvania

Attending Physician

Department of Pediatrics

The Children's Hospital of Philadelphia

Philadelphia, Pennsylvania

Peter J. Tebben, MD

Assistant Professor
Departments of Internal Medicine and Pediatrics
Mayo Clinic
Rochester, Minnesota

Jennifer A. F. Tender, MD, IBCLC

Assistant Professor
Department of General Pediatrics
The George Washington University School of Medicine & Health Services
Attending Physician
General Pediatrics
The Children's National Health System
Washington, DC

M. Elizabeth Tessier, MD

Pediatric GI, Hepatology & Nutrition Fellow
Division of Pediatrics
Baylor College of Medicine
Texas Children's Hospital
Houston, Texas

Sheila Thampi, MD

Clinical Fellow-Hematology & Oncology
Department of Pediatrics
University of California, San Francisco
San Francisco, California

Liu Lin Thio, MD, PhD

Associate Professor of Neurology, Pediatrics and Anatomy &
Neurobiology
Director, Pediatric Epilepsy Center
Washington University School of Medicine
St. Louis Children's Hospital
St. Louis, Missouri

Joanna E. Thomson, MD

Attending Physician
Division of Hospital Medicine
Cincinnati Children's Hospital Medical Center
Cincinnati, Ohio

Shannon Thyne, MD

Professor of Clinical Pediatrics
Department of Pediatrics
University of California, San Francisco
Chief of Medical Staff
San Francisco General Hospital
San Francisco, California

John E. Tis, MD

Assistant Professor
Department of Orthopedic Surgery
The Johns Hopkins Hospital
Baltimore, Maryland

Laura L. Tosi, MD

Orthopaedic Surgeon
Children's National Health System
Washington, DC

James R. Treat, MD

Pediatric Dermatologist
Division of Dermatology
The Children's Hospital of Philadelphia
Philadelphia, Pennsylvania

Maria E. Trent, MD, MPH

Associate Professor
Department of Pediatrics
The Johns Hopkins University School of Medicine
Faculty

Pediatrics
Johns Hopkins Children's Center
Baltimore, Maryland

Nicholas Tsarouhas, MD

Professor of Clinical Pediatrics
Department of Pediatrics
Perelman School of Medicine at the University of Pennsylvania
Medical Director, Emergency Transport Team
Associate Medical Director, Emergency Department
Division of Emergency Medicine
The Children's Hospital of Philadelphia
Philadelphia, Pennsylvania

Shamir Tuchman, MD, MPH

Assistant Professor of Pediatrics
Division of Pediatric Nephrology
The George Washington University School of Medicine & Health
Sciences
Attending Nephrologist
Division of Pediatric Nephrology
Children's National Medical Center
Washington, DC

Krishna K. Upadhyia, MD, MPH

Assistant Professor
Department of Pediatrics
The Johns Hopkins University School of Medicine
Baltimore, Maryland

Susma Vaidya, MD, MPH

Assistant Professor of Pediatrics
Department of General Pediatrics
The George Washington University School of Medicine & Health
Sciences
Children's National Medical Center

Washington, DC

Kristin L. Van Buren, MD

Assistant Professor of Pediatrics

Division of Pediatrics, Gastroenterology, Hepatology & Nutrition

Baylor College of Medicine

Assistant Professor of Pediatrics

Division of Pediatrics, Gastroenterology, Hepatology & Nutrition

Texas Children's Hospital

Houston, Texas

Gigi Veereman, MD, PhD

Professor

Department of Pediatrics

Free University of Brussels (VUB)

Consultant

Department of Pediatric Gastroenterology and Nutrition

University Hospital Brussels

Belgium

Hilary Vernon, MD, PhD

Assistant Professor

McKusick-Nathans Institute of Genetic Medicine and Department of
Medicine

Division of Pediatrics

McKusick-Nathans Institute of Genetic Medicine

The Johns Hopkins University School of Medicine

Baltimore, Maryland

Elliott Vichinsky, MD

Medical Director, CHO Hematology/Oncology Programs

UCSF Benioff Children's Hospital Oakland

Oakland, California

Kieuhoa T. Vo, MD

Clinical Fellow

Department of Pediatrics
University of California, San Francisco
UCSF Benioff Children's Hospital San Francisco
San Francisco, California

Patricia Vuguin, MD, MSc

Associate Professor of Pediatrics
Department of Pediatrics
School of Medicine at Hofstra University
Hempstead, New York
Pediatric Endocrinology Fellowship Director
Pediatric Endocrinology
Cohen Children's Medical Center
New Hyde Park, New York

R. Paul Wadwa, MD

Associate Professor of Pediatrics
Barbara Davis Center for Childhood Diabetes
University of Colorado School of Medicine
Aurora, Colorado

Lars M. Wagner, MD

Professor of Pediatrics
Division of Pediatric Hematology/ Oncology
University of Kentucky
Chief, Pediatric Hematology/Oncology
Department of Pediatrics
Kentucky Children's Hospital
Lexington, Kentucky

Waqar Waheed, MD

Assistant Professor
Department of Neurological Sciences
University of Vermont
Burlington, Vermont

Justin T. Wahlstrom, MD

Assistant Professor
Department of Pediatrics
University of California, San Francisco
UCSF Children's Hospital
San Francisco, California

Elizabeth M. Wallis, MD

Assistant Professor
Department of Pediatrics
Medical University of South Carolina
Charleston, South Carolina

Daniel Walmsley, DO

Clinical Assistant Professor of Pediatrics
Pediatric Clerkship Site Director
Jefferson Medical College/ Nemours
Pediatrician
Nemours Pediatrics, Thomas Jefferson University Hospital
Philadelphia, Pennsylvania

Ming-Hsien Wang, MD

Assistant Professor
Department of Urology
The Johns Hopkins University School of Medicine
Assistant Professor
Department of Pediatric Urology
The Johns Hopkins Hospital
Baltimore, Maryland

Dascha C. Weir, MD

Instructor in Pediatrics
Harvard Medical School
Associate Director
The Celiac Disease Program
Attending Physician

Division of Gastroenterology, Hepatology & Nutrition
Boston Children's Hospital
Boston, Massachusetts

Peter Weiser, MD

Assistant Professor
Division of Rheumatology, Department of Pediatrics
The University of Alabama at Birmingham
Children's of Alabama
Birmingham, Alabama

Marceé J. White, MD

Assistant Professor
Department of General Pediatrics
The George Washington University
Medical Director
Mobile Health Programs
Children's National Medical Center
Washington, DC

Benjamin M. Whittam, MD, MS

Assistant Professor
Department of Urology-Pediatric Urology
Indiana University School of Medicine
Riley Hospital for Children at Indiana University Health
Indianapolis, Indiana

M. Edward Wilson, MD

N. Edgar Miles Professor of Ophthalmology and Pediatrics
Department of Ophthalmology
Storm Eye Institute
Medical University of South Carolina
Charleston, South Carolina

Erica Winnicki, MD

Assistant Professor

Department of Pediatrics
Section of Nephrology
University of California, Davis
Department of Pediatrics,
Section of Nephrology
UC Davis Medical Center
Sacramento, California

Sarah E. Winters, MD

Clinical Assistant Professor of Pediatrics
Department of Pediatrics
Perelman School of Medicine at the University of Pennsylvania
Philadelphia, Pennsylvania

Elaine C. Wirrell, MD

Director of Pediatric Epilepsy
Consultant
Child and Adolescent Neurology and Epilepsy
Mayo Clinic
Rochester, Minnesota

Thomas E. Wiswell, MD

Professor
Department of Pediatrics
University of Central Florida
Attending Neonatologist
Department of Pediatrics
Florida Hospital for Children
Orlando, Florida

Selma Feldman Witchel, MD

Associate Professor of Pediatrics
Department of Pediatrics
University of Pittsburgh
Fellowship Director
Pediatrics

Children's Hospital of Pittsburgh of UPMC
Pittsburgh, Pennsylvania

Char Witmer, MD, MSCE

Assistant Professor
Department of Pediatrics
Perelman School of Medicine at the University of Pennsylvania
Philadelphia, Pennsylvania

Margaret Wolff, MD

Assistant Professor
Departments of Emergency Medicine and Pediatrics
University of Michigan
Faculty
Department of Emergency Medicine
University of Michigan, C.S. Mott Children's Hospital
Ann Arbor, Michigan

Mark Wolraich, MD

Chief of Section of Developmental and Behavioral Pediatrics
Department of Pediatrics
University of Oklahoma Health Sciences Center
Oklahoma City, Oklahoma

Lily C. Wong-Kisiel, MD

Assistant Professor
Department of Neurology
Mayo Clinic
Rochester, Minnesota

George Anthony Woodward, MD, MBA

Professor
Department of Pediatrics
University of Washington School of Medicine
Chief, Medical Director

Pediatric Emergency Medicine
Seattle Children's Hospital
Seattle, Washington

Hsi-Yang Wu, MD

Associate Professor
Department of Urology
Stanford University
Stanford, California
Fellowship Program Director
Pediatric Urology
Lucile Packard Children's Hospital Stanford
Palo Alto, California

Menno Verhave, MD

Lecturer
Harvard Medical School
Attending Physician
Clinical Director, Gastroenterology
Division of Gastroenterology, Hepatology & Nutrition
Boston Children's Hospital
Boston, Massachusetts

Desalegn Yacob, MD

Assistant Professor
Department of Pediatrics
The Ohio State University
Attending Pediatric Gastroenterologist
Pediatric Gastroenterology
Nationwide Children's Hospital
Columbus, Ohio

Jennifer Yang, MD

Assistant Professor
Department of Urology
University of California, Davis

Sacramento, California

Michael Yaron, MD

Professor of Emergency Medicine
Department of Emergency Medicine
University of Colorado School of Medicine
Attending Physician
Emergency Department
University of Colorado Hospital
Aurora, Colorado

Yvette E. Yatchmink, MD, PhD

Associate Professor (Clinical)
Division of Developmental Behavioral Pediatrics
The Warren Alpert Medical School of Brown University
Departmental-Behavioral Pediatrician
Children's NeuroDevelopment Center
Hasbro Children's, Rhode Island Hospital
Providence, Rhode Island

Robert F. Yellon, MD

Professor of Otolaryngology
Department of Otolaryngology
University of Pittsburgh School of Medicine
Director of Clinical Services, and Co-Director
Department of Pediatric Otolaryngology
Children's Hospital of Pittsburgh of UPMC
Pittsburgh, Pennsylvania

Elizabeth H. Yen, MD

Assistant Professor
UCSF Benioff Children's Hospital San Francisco
Department of Pediatrics
Division of Gastroenterology, Hepatology and Nutrition
San Francisco, California

M. Elizabeth M. Younger, CRND, PhD

Assistant Professor

Department of Pediatric Allergy & Immunology
The Johns Hopkins University School of Medicine
Program Coordinator

Department of Pediatric Immunology
The Johns Hopkins Hospital
Baltimore, Maryland

Jenny Yu, MD

Assistant Professor

Division of Neonatology
The Johns Hopkins University School of Medicine
Neonatologist

ABDOMINAL MASS

Maireade E. McSweeney • Rose C. Graham

BASICS

DESCRIPTION

A palpable lesion or fullness in the abdominal cavity which may or may not be related to abdominal viscera; the mass may be abdominal or retroperitoneal in origin

EPIDEMIOLOGY

- Etiologies for abdominal masses are varied and the differential depends on age and anatomic location.
- Majority are nonsurgical in nature; many are associated with constipation.
- Approximately 57% of abdominal masses in children are due to organomegaly (hepatomegaly or splenomegaly).

DIAGNOSIS

- Stomach
 - Gastric distension or gastroparesis
 - Duplication
 - Foreign body or bezoar
 - Gastric torsion
 - Gastric tumor (lymphoma, sarcoma)
- Intestine
 - Feces (constipation)
 - Intestinal distension or toxic megacolon
 - Foreign body
 - Meconium ileus
 - Duplication
 - Volvulus
 - Intussusception

- Intestinal atresia or stenosis
- Malrotation
- Complications of inflammatory bowel disease (abscess, phlegmon)
- Appendiceal inflammation
- Meckel diverticulum or abscess
- Duodenal hematoma (trauma)
- Lymphoma, adenocarcinoma, GI stromal tumor
- Carcinoid (appendiceal)
- Liver
 - Hepatomegaly due to intrinsic liver disease
 - Hepatitis (e.g., infectious, autoimmune)
 - Metabolic or storage disorders (e.g., Wilson disease, glycogen storage disease)
 - Infiltration of liver (cyst, tumors)
 - Biliary obstruction
 - Vascular obstruction/impaired venous congestion (Budd-Chiari syndrome, congestive heart failure)
 - Cystic disease (e.g., Caroli disease)
 - Solid tumor (hepatoblastoma; hepatocellular carcinoma; hepatic adenoma; or other diffuse, systemic, neoplastic process)
 - Vascular tumor (hemangioma or hemangioendothelioma)
 - Other: hamartomas, focal nodular hyperplasia
- Gallbladder/biliary tract
 - Choledochal cyst
 - Hydrops of gallbladder
 - Obstruction (stone, stricture, trauma)
- Spleen
 - Congenital cysts
 - Storage disease (e.g., Gaucher, Niemann-Pick)
 - Langerhans cell histiocytosis
 - Leukemia
 - Hematologic (hemolytic disease [e.g., sickle cell] or other RBC disorders [e.g., hereditary spherocytosis])
 - Portal hypertension
 - Wandering spleen

- Pancreas
 - Congenital cysts
 - Pseudocyst (trauma, pancreatitis)
 - Pancreatoblastoma
 - Neuroendocrine tumors (insulinomas, gastrinomas)
 - Solid and papillary epithelial neoplasms
- Kidney
 - Hydronephrosis or ureteropelvic obstruction
 - Multicystic dysplastic kidney
 - Polycystic disease
 - Tumor (mesoblastic nephroma, Wilms tumor, renal cell carcinoma)
 - Renal vein thrombosis
 - Cystic nephroma
- Bladder
 - Bladder distension
 - Neurogenic bladder
- Adrenal
 - Adrenal hemorrhage
 - Adrenal abscess
 - Neuroblastoma
 - Pheochromocytoma
- Uterus
 - Pregnancy
 - Hematocolpos
 - Hydrocolpos or hydrometrocolpos
- Ovary
 - Cysts (dermoid, follicular)
 - Torsion
 - Germ cell tumor
- Peritoneal
 - Ascites
 - Teratoma
- Abdominal wall
 - Umbilical/inguinal/ventral hernia
 - Omphalocele/gastroschisis

- Urachal cyst
- Trauma (rectus hematoma)
- Tumor (fibroma, lipoma, rhabdomyosarcoma)
- Omentum/mesentery
 - Cysts
 - Mesenteric fibromatosis
 - Mesenteric adenitis
- Other
 - Tumors (liposarcoma, leiomyosarcoma, fibrosarcoma, mesothelioma)
 - Intra-abdominal testicle (torsion)
 - Lymphangioma
 - Fetus in fetu
 - Sacrococcygeal teratoma

APPROACH TO PATIENT

When evaluating a pediatric abdominal mass, an organized approach is critical:

- **Phase 1:** Perform a careful clinical history and abdominal examination in order to help assess clinical symptoms, duration of symptoms, and approximate anatomic location of the mass.
- **Phase 2:** Perform diagnostic tests:
 - Obtain abdominal x-ray to assess for bowel obstruction, fecal load, or mass effect; obtain ultrasound to identify organ of origin and tissue components (e.g., cystic, hemorrhage, etc.).
 - Laboratory testing as indicated
- **Hints for screening problems**
 - Constipation and fecal impaction can present as a large, hard mass extending from the pubis.
 - In neonates, a palpable liver edge can be normal; assess the total liver span.
 - In infants, a full bladder is often mistaken for an abdominal mass.
 - Certain genetic disorders/syndromes are associated with increased risk of tumor development (e.g., Beckwith-Wiedemann syndrome and Wilms tumor).
 - Gastric distention should be considered in all children who present

with a tympanitic epigastric mass.

HISTORY

- **Question:** Weight loss?
- Significance: Malignancy, inflammatory bowel disease
- **Question:** Fever?
- Significance: Infection, malignancy
- **Question:** Jaundice?
- Significance: Hepatobiliary or hematologic disease
- **Question:** Hematuria or dysuria?
- Significance: Renal disease
- **Question:** Vomiting, bilious vomiting, or early satiety?
- Significance: Intestinal obstruction
- **Question:** Abdominal pain?
- Significance: Appendicitis, intussusception, intestinal obstruction
- **Question:** Frequency and quality of bowel movements?
- Significance: Constipation, intussusception, compression of bowel by mass
- **Question:** Bleeding or bruising?
- Significance: Liver disease, coagulopathy
- **Question:** Pallor or weakness?
- Significance: Sign of anemia or blood loss
- **Question:** History of abdominal trauma?
- Significance: Pancreatic pseudocyst, duodenal hematoma
- **Question:** Sexual activity?
- Significance: Pregnancy
- **Question:** Age of patient?
- Significance:
 - In neonates, the most common origin of abdominal masses are genitourinary (cystic kidney disease, hydronephrosis).
 - In adolescent-aged girls, ovarian disorders, hematocolpos, and pregnancy should be considered.
 - Most common malignant abdominal tumors by age: (1) infants: neuroblastoma, Wilms tumor; (2) children: Wilms tumor, sarcomas, germ cell tumors, (3) children >10 years of age: sarcomas, germ cell tumors, and abdominal lymphomas

PHYSICAL EXAM

- **Finding:** General appearance?
- Significance: Ill appearance or cachexia point toward infection or malignancy.
- **Finding:** Location of abdominal mass?
- Significance:
 - Left lower quadrant: feces, ovarian process, ectopic pregnancy
 - Left upper quadrant: splenomegaly, anomaly of the kidney
 - Right lower quadrant: abscess (inflammatory bowel disease), intestinal phlegmon, appendicitis, intussusception, ovarian process, ectopic pregnancy
 - Right upper quadrant: liver, gallbladder, biliary tree, or intestine
 - Epigastric: abnormality of the stomach (bezoar, torsion), pancreas (pseudocyst), or enlarged liver
 - Suprapubic: pregnancy, hydrometrocolpos, hematoocolpos, posterior urethral valves
 - Flank: renal disease (cystic kidney, hydronephrosis, Wilms tumor)
- **Finding:** Characteristics of abdominal mass?
- Significance: Mobility, tenderness, firmness, smoothness, and/or irregularity of the surface of the mass can provide clues to its significance.
- **Finding:** Hard and immobile mass?
- Significance: Tumor
- **Finding:** Extension of mass across midline or into pelvis?
- Significance: Tumor, hepatomegaly, splenomegaly
- **Finding:** Percussion of mass?
- Significance: Dullness indicates a solid mass; tympany indicates a hollow organ.
- **Finding:** Shifting dullness, fluid wave?
- Significance: Ascites
- **Finding:** Skin exam?
- Significance: Bruising and petechiae may occur with coagulopathy related to liver disease and malignant infiltration of bone marrow; café au lait spots are associated with neurofibromas.
- **Finding:** Lymphadenopathy or lymphadenitis?

- Significance: Systemic process either malignant or infectious
- **Finding:** Peritoneal signs?
- Significance: Appendicitis, bowel obstruction or perforation; indication for urgent surgical consultation
- **Finding:** Rectal bleeding?
- Significance: Intestinal inflammation, polyp, or other bleeding lesion

DIAGNOSTIC TESTS & INTERPRETATION

- **Test:** CBC with differential
- Significance: Anemia, hemolysis
- **Test:** Chemistry panel
- Significance:
 - Renal disease: BUN and creatinine levels
 - Liver disease (bilirubin, ALT, AST, alkaline phosphatase, GGT, albumin, PT/PTT)
 - Gallbladder disease (bilirubin, GGT)
 - Pancreatic disease: amylase/lipase levels
 - Intestinal disease: hypoalbuminemia
- **Test:** Uric acid and lactate dehydrogenase levels
- Significance: Elevated in the setting of rapid cell turnover of solid tumors
- **Test:** Serum quantitative beta-human chorionic gonadotropin (hCG)
- Significance: Pregnancy, germ cell tumor

Imaging

- Plain radiographs
 - Evaluate for intestinal obstruction (dilated bowel loops, air fluid levels), bowel gas pattern, calcifications, or fecal impaction; urinary retention
- Ultrasound
 - Can identify the origin of the mass and differentiate between solid and cystic tissue; Doppler ability can help assess vascularity. Disadvantage is operator variability, and visualization may be limited by overlying bowel gas.
- CT scan
 - Can provide more detail when there is overlying gas or bone; if

malignancy is suspected, should also do chest in addition to abdomen and pelvis

- MRI
 - Vascular lesions of liver, major vessels, and tumors
- Nuclear medicine
 - Radioisotope cholescintigraphy (HIDA) scan of liver, gallbladder/biliary tree
 - Meckel scan: can identify gastric mucosa contained within a Meckel diverticulum or intestinal duplication
 - Intravenous urography to assess renal system
- Fluoroscopy
 - Upper GI studies and barium enema studies: may be of benefit when the mass involves the intestine
 - Voiding cystourethrography (VCUG) to assess renal system

TREATMENT

GENERAL MEASURES

- Immediate hospitalization for patients who present with an abdominal mass and/or signs of dehydration, intestinal obstruction, bleeding, feeding intolerance, or clinical decompensation
- In addition to initial diagnostic and laboratory testing, a pediatric surgical or oncologic consultation should be obtained as indicated.
- The remaining causes of abdominal masses require urgent care and timely evaluation and referral to appropriate specialists.

ISSUES FOR REFERRAL

Except for the diagnosis of constipation, the presence of an abdominal mass in children requires immediate attention, and diagnostic studies should be performed expeditiously at a pediatric health care facility.

Admission Criteria

- Immediate hospitalization for patients who present with an abdominal mass and signs and/or symptoms of intestinal obstruction, distension, or peritoneal symptoms (intussusception, volvulus, gastric torsion, bezoar, foreign body, appendicitis)

- Toxic megacolon
- Ovarian torsion
- Ectopic pregnancy
- Biliary obstruction (stone, hydrops)
- Fever
- Anemia, coagulopathy
- Pancreatitis (pseudocyst)
- The remaining causes of abdominal masses require urgent care and timely evaluation and referral to appropriate specialists.

- R16.1 Splenomegaly, not elsewhere classified

ABDOMINAL MIGRAINE

Desalegn Yacob

BASICS

DESCRIPTION

Paroxysmal disorder of an acute onset, severe, noncolicky, periumbilical abdominal pain accompanied variably with nausea, vomiting, anorexia, headache, and pallor

EPIDEMIOLOGY

Incidence

- Occurs mostly in children; mean onset at age 7 years (3–10 years)
- Peak symptoms 10–12 years of age
- More common in girls (3:2)

Prevalence

- May affect as many as 1–4% of children at some point in their lives
- Declining frequency toward adulthood

RISK FACTORS

Genetics

Parents of affected children often have history of migraine headaches and motion sickness.

ETIOLOGY

- May involve neuronal activity originating in the hypothalamus with involvement of the cortex and autonomic nervous system
- Serotonin is implicated, and blockade of serotonin receptors may prevent abdominal migraine.
- Recent studies suggest involvement of local intestinal vasomotor factors

DIAGNOSIS

Rome III criteria—2 episodes within 12 months meeting all of the

following criteria:

- Paroxysmal intense periumbilical pain that lasts >1 hour
- Intervening episodes of health between episodes
- Pain that interferes with activity
- Pain associated with ≥ 2 of the following: anorexia, nausea, vomiting, headache, photophobia, or pallor
- No evidence of inflammatory, anatomic, metabolic, or neoplastic process
- No evidence of elevated intracranial pressure (tumor, hydrocephalus)

HISTORY

- Ask about a family history of migraine headache or unexplained bouts of abdominal pain as children.
- Pain typically lasts <6 hours.
- Generalized abdominal pain; can often be localized to upper quadrants
- No abdominal pain between episodes
- Repetition of identical abdominal crises, anywhere from 1 time per week to several times a year
- Migraine in the history of patient or relatives
- Occasionally, other migraine phenomena such as nausea, vomiting, perspiration, body temperature changes, focal paresthesias, radiation of pain to a limb, visual disturbances, or general malaise
- Associated fatigue, lethargy, or impairment of consciousness

PHYSICAL EXAM

- Physical exam, including complete neurologic and abdominal exam, is usually unremarkable.
- Complete eye exam including funduscopic exam should be done to evaluate for papilledema (elevated intracranial pressure).

DIAGNOSTIC TESTS & INTERPRETATION

- Abdominal migraine is a diagnosis of exclusion.
- Even if a patient meets most or all diagnostic criteria for abdominal migraine, studies as outlined below should be strongly considered to ensure that another serious disorder does not exist.

Lab

- CBC with differential
- ESR and CRP
- Urinalysis
- Pregnancy test
- Amylase and lipase
- Stool Hemocult
- Stool culture
- Lactose breath test for lactose intolerance
- Lead level
- Evaluation for porphyria or familial Mediterranean fever
- Metabolic evaluation (obtain during symptomatic episode, not during quiescence): urine organic acids, plasma amino acids, ammonia, lactate, blood gas, acylcarnitine profile, imaging

Diagnostic Procedures/Other

- Obstruction series to assess for intermittent or partial bowel obstruction
- Upper GI to rule out anatomic abnormalities
- US or CT scan to rule out mass lesion or chronic appendicitis
- Renal US during episodes to rule out ureteropelvic junction (UPJ) obstruction
- Barium enema (during painful crisis) to rule out intussusception
- EEG may help differentiate between abdominal migraine and epilepsy.
- Visual evoked response (VER) to red and white flashlight: Children with abdominal migraine may display a specific fast-wave activity response.
- Rarely, brain imaging with CT or MRI may be useful for evaluating causes of intermittent hydrocephalus.

DIFFERENTIAL DIAGNOSIS

- Infection
 - Giardia
- Environmental
 - Lead intoxication
- Tumors
- Metabolic
 - Porphyria, lactose intolerance, female carriers of (X-linked)

ornithine transcarbamylase (OTC) gene mutation, organic acidemias

- Psychosocial
 - Functional abdominal pain/irritable bowel syndrome
- Surgical
 - Appendicitis, intussusception, biliary colic
- Inflammation
 - Inflammatory bowel disease, peptic ulcer disease, mesenteric adenitis
- GI
 - Irritable bowel syndrome, gastroesophageal reflux, wandering spleen, cyclical vomiting syndrome, recurrent abdominal pain, functional abdominal pain, constipation, superior mesenteric artery (SMA) syndrome, recurrent pancreatitis
- Anatomic
 - Meckel diverticulum, UPJ obstruction
- Neurologic
 - Abdominal epilepsy—but has a shorter duration of pain (minutes), altered consciousness during event, abrupt onset, abnormal discharges in EEG in 80%
 - Temporal lobe epilepsy
 - Intermittent hydrocephalus (possibly secondary to a 3rd ventricle colloid cyst)

ALERT

Because it is usually a diagnosis of exclusion, many patients go through a large workup to rule out other causes of pain, sometimes including laparotomy.

TREATMENT

MEDICATION

- Medications can be used to abort acute attacks or be taken as daily prophylaxis.
- For most patients, risks of side effects and complications from the use of these medications may outweigh the relief of pain, especially in

children who are experiencing infrequent episodes.

- Limited data exist on abortive agents for abdominal migraines; however, several agents have shown benefit in specialty-based clinical practice, including metoclopramide, steroids, intranasal sumatriptan, and NSAIDs (although the latter may be avoided if there are clinical concerns for gastritis or peptic ulcer disease). Consider benzodiazepines (i.e., lorazepam) and antiemetics (i.e., ondansetron) for vomiting-predominant symptoms.
- Suggested prophylactic treatments are similar to those for migraine headaches and include tricyclic antidepressants (e.g., amitriptyline), topiramate, propranolol, cyproheptadine, and valproic acid. If EEG or other data point to possible epilepsy, empiric treatment with anticonvulsants may be considered.

ADDITIONAL TREATMENT

General Measures

- Trigger avoidance
 - An event diary should be kept to identify possible migraine triggers.
 - Avoiding triggers is the most optimal strategy for preventing recurrent attacks:
 - Common triggers include caffeine, nitrites, amines, emotional arousal, travel, prolonged fasting, altered sleep, exercise, and/or flickering lights.
- Cognitive therapies
 - Behavioral therapies and lifestyle modification (regular sleep, hydration, and exercise) may also be of benefit. Biofeedback in conjunction with other cognitive therapies and/or relaxation programs may be helpful. Assistance from a trained pediatric mental health professional may be useful.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Most children outgrow abdominal migraine symptoms (~60%) by early adolescence.

- A substantial percentage of patients (~70%) may develop more typical migraine headaches during adulthood.
- Although nonspecific EEG changes are seen more commonly in this condition, very few children go on to develop epilepsy.
- 10% of children who have a diagnosis of migraine headaches have previously suffered from unexplained recurrent abdominal pain.
- Adult migraine headache sufferers experience abdominal pain more frequently than do tension headache sufferers.

PATIENT EDUCATION

- To help child during bouts of pain, allow the child to do whatever makes him or her comfortable—rest, positioning, being quiet.
- Whether the patient should be excused from school depends on various factors:
 - Frequency, severity, and duration of pain
 - Age, maturity, and coping skills of the child

- G43.D1 Abdominal migraine, intractable

FAQ

- Q: Does this diagnosis mean my child will develop migraine headaches?
- A: There is no accurate way to predict whether your child will develop migraine headaches.
- Q: I have 2 younger children. What chance do they have of developing abdominal migraines?
- A: Although migraine headaches do tend to run in families, there is no known mendelian inheritance pattern.
- Q: What can I do to help my child during bouts of pain?
- A: First, allow the child to do whatever makes him or her comfortable. This may mean resting, positioning, or being quiet. Acetaminophen or NSAID-based pain relievers may help to a certain degree. Whether the patient should be excused from school depends on various factors such as the frequency, severity, and duration of the pain as well as the age, maturity, and coping skills of the child.
- Q: My child is having frequent episodes that are affecting his/her quality of life. What can we do?
- A: It may be appropriate to trial him/her on prophylactic daily medications.

ABDOMINAL PAIN

Adrienne M. Scheich

BASICS

DESCRIPTION

- Abdominal pain is a subjective symptom that can originate from any intra-abdominal organ but also be secondary to non-abdominal sources (e.g., peridiaphragmatic conditions [e.g., pneumonia], referred pain, systemic infection [e.g., strep A or viral pharyngitis], depression).
- Acute abdominal pain is often due to benign and self-limited etiologies but may also be due to potentially life-threatening conditions.
- Chronic abdominal pain, defined as present >2 months, can either be of organic origin (anatomic, infectious, inflammatory, or metabolic) or, more frequently, part of a functional gastrointestinal disorder (FGID) based on specific diagnostic criteria (Rome III).

EPIDEMIOLOGY

- Abdominal pain is one of the most common complaints in pediatric patients.
- Chronic abdominal pain represents 2–4% of general pediatrics office visits and more than 50% of pediatric gastroenterology visits and can be associated with significant morbidity. Thus, chronic pain also warrants careful consideration and management.

PATHOPHYSIOLOGY

- The nature of abdominal pain is multifactorial and may evolve in nature over time (i.e., in acute appendicitis, pain typically migrates from periumbilical to right lower quadrant).
- Visceral pain (particularly from small intestine) is often poorly localized and is described as dull, diffuse, cramping, or burning. Visceral pain may be associated with autonomic reflex responses (diaphoresis, pallor, nausea, and/ or vomiting).
- More localized, sharp somatoparietal pain typically indicates peritoneal involvement (appendicitis, cholecystitis).

- Referred pain is related to the level of spinal cord entry of visceral afferent nerves (e.g., scapular pain in cholecystitis).

ETIOLOGY

- Right upper quadrant
 - Cholelithiasis/cholecystitis
 - Hepatitis/perihepatitis
 - Nephrolithiasis
 - Ureteropelvic junction obstruction
 - Right lower lobe pneumonia
- Epigastric area
 - Gastroesophageal reflux disease (GERD)
 - Esophagitis (GERD, eosinophilic)
 - Gastritis (NSAID, allergic, Helicobacter pylori, Crohn disease)
 - Functional dyspepsia
 - Ulcer disease (NSAID, H. pylori)
 - Pancreatitis
 - Cholecystitis
 - Gastric/small intestinal volvulus
- Left upper quadrant
 - Splenic hematoma
 - Renal disease (see above)
 - Left lower lobe pneumonia
 - Constipation
- Right lower quadrant
 - Appendicitis/perforation/psoas abscess
 - Mesenteric adenitis
 - Intussusception
 - Inflammatory bowel disease (IBD)
 - Infection (tuberculosis, Yersinia)
 - Ovarian/testicular torsion
 - Ectopic pregnancy
 - Inguinal hernia
- Left lower quadrant
 - Constipation
 - Colitis (inflammatory/infectious)

- Sigmoid volvulus
- Genitourinary disease (see above)
- Hypogastric area
 - Constipation
 - Colitis
 - Cystitis
 - Dysmenorrhea/uterine disease
 - Pelvic inflammatory disease
- Periumbilical area
 - FGID
 - Constipation
 - Gastroenteritis (infectious/eosinophilic)
 - Pancreatitis
 - Gastric/small bowel volvulus
 - Appendicitis (early)
 - Incarcerated umbilical hernia
- Diffuse
 - Constipation
 - FGID
 - Giardiasis
 - Carbohydrate malabsorption
 - Celiac disease
 - Streptococcal/viral pharyngitis
 - IBD
 - Allergic/eosinophilic gastroenteritis
 - Ischemic necrotizing enterocolitis (NEC)
 - Perforation/peritonitis
 - Malrotation with volvulus
 - Lead/iron poisoning/pica syndrome
 - Cyclic vomiting syndrome
 - Porphyria
 - Sickle cell crisis
 - Familial Mediterranean fever
 - Diabetic ketoacidosis
 - Henoch-Schönlein purpura (HSP)

- Tumor
- Trauma
- Hemolytic uremic syndrome (HUS)

DIAGNOSIS

APPROACH TO PATIENT

Initial step is to establish the acuity and severity of symptoms and to rule out a potentially life-threatening emergency (e.g., appendicitis, perforation, bowel obstruction associated with volvulus, adhesions, or intussusception).

HISTORY

- Onset and duration of symptoms
 - Acute versus chronic
- Age of patient may be indicative of certain etiologies particularly in acute presentation.
 - NEC (newborn/prematurity), malrotation/volvulus (80% present in first month of life), intussusception (more frequent in infants/toddlers), foreign body ingestion in young child
- Localization and radiation of pain
 - May point to specific organ—see etiologies
- Triggering or relieving factors
 - Meals/spices, specific foods (lactose, sucrose)
 - General position with knees bent can be relieving in acute appendicitis.
 - Pain relieved by defecation (constipation) versus pain worsened by defecation (colitis)
- Bowel pattern and stool appearance
 - Stool frequency and consistency: diarrhea versus constipation
 - Urgency or nocturnal diarrhea (colitis)
 - Presence of bloating and excessive flatulence (giardiasis, carbohydrate malabsorption)
 - Presence of mucus (may be normal but can be associated with colitis)
 - Hematochezia (fissure, hemorrhoid, polyp, colitis, HSP); if bright

- red “currant jelly” appearance, suspect intussusception
 - Melena (upper gastrointestinal bleeding/ulcer)
 - Pale/acholic stools (hepatic or biliary disease)
 - Perirectal disease (IBD)
- Anorexia/nausea/vomiting
 - If postprandial, indicative of upper gastrointestinal condition; nausea may be functional.
 - May indicate extraintestinal disease (urinary tract infection, UPJ obstruction, or pneumonia)
 - Hematemesis suggests esophagitis/gastritis; more significant blood volume suggests ulcer disease, Mallory-Weiss tear (lower esophagus)
 - Bilious emesis indicates intestinal obstruction (volvulus, intussusception, NEC in newborns)
- Dysphagia/food impaction
 - In older children, suspect eosinophilic esophagitis
 - GERD
- Fever
 - Acute infection, acute appendicitis, chronic inflammatory process
- Weight loss/growth failure/delayed puberty
 - Chronic inflammatory process, celiac disease
- Extraintestinal symptoms
 - Dysuria
 - Skin rash (atopy may point to eosinophilic process; purpura: abdominal pain may be first symptom of HSP)
 - Respiratory symptoms (pneumonia)
 - Arthralgias (IBD, HSP)
- Preexisting conditions (infectious diarrhea preceding HUS; hemoglobinopathy or cystic fibrosis risk factors for cholecystitis)
- Exposures
 - Lead/iron in young children
 - Travel/well water/pets (giardiasis)
 - Insect bite (HSP)
 - NSAID use (gastritis)
 - Tetracycline (pill esophagitis)

- Dietary history to assess fiber and fluid intake; excessive use of sugar-free gum (sorbitol malabsorption); intake of sucrose-, fructose-, or lactose-containing foods (various disaccharidase deficiencies, most commonly lactose intolerance)
- Prior abdominal surgical history (adhesions)
- Family history of IBD, H. pylori, celiac disease, atopy, migraine
- Social history and identification of stressors, school attendance, signs of mood disorder

PHYSICAL EXAM

- In an acute setting, an abdominal exam may need to be serially performed, as location of pain may change over time.
- Signs of acute appendicitis:
 - Exquisite pain at McBurney point on percussion or palpation
 - Involuntary guarding
 - Rovsing sign (palpation LLQ), psoas sign, obturator sign
 - Rebound tenderness (peritoneal inflammation)
 - Pain on movement (walking, jumping)
 - Pain may be relieved temporarily if the appendix ruptures followed by signs of peritonitis.
 - Right upper quadrant pain on inspiration (cholecystitis)
 - Flank tenderness (renal pathology)
 - Perianal examination may reveal skin tags/fissures (constipation, IBD), perianal abscess (IBD), hemorrhoids
- Rectal examination done carefully can be indicative of
 - Peritoneal irritation (appendicitis/peritonitis)
 - Hematochezia (IBD, HSP), perianal disease
 - Fecal retention/abnormal sphincter tone (anal stricture, absent relaxation of IAS suggesting anal achalasia)
- Skin rashes (eczema, purpura)
- Other signs of chronic disease include pallor, clubbing, edema

DIAGNOSTIC TESTS & INTERPRETATION

- Laboratory testing, if any, should be carefully guided by the history and clinical picture.
 - If a benign acute condition such as acute viral gastroenteritis is

suspected, any further testing can be delayed with close follow-up (in absence of clinical evidence of dehydration).

- In the presence of “red flags” (see “[Referral](#)”), blood and stool testing should be performed
- CBC/differential
 - Leukocytosis (appendicitis/abscess, acute infectious process); normal white blood cell count may indicate low risk for acute appendicitis
 - Anemia (gastrointestinal blood loss)
 - Microcytosis (chronic inflammation, IBD, celiac disease)
- Elevated ESR or CRP (acute infection, chronic inflammation)
- Hypoalbuminemia and low ferritin (IBD, celiac disease); diarrhea may be absent
- Pancreatic enzymes, hepatic enzymes
- Fecal cultures in the presence of bloody diarrhea (colitis); ova and parasites (giardiasis)
- Fecal calprotectin and lactoferrin (inflammation or infection)
- Urinalysis to rule out urinary tract infection (leukocyturia may be present in acute appendicitis)
- Celiac screening (anti-tissue transglutaminase IgA or anti-endomysial IgA in presence of normal total IgA levels) should be considered if abdominal pain and/or constipation do not respond to bowel regimen or if unexplained diarrhea, weight loss/growth failure; also at risk: type 1 diabetes, autoimmune thyroiditis, Down/Turner syndrome
- Thyroid screen if abdominal pain/chronic constipation unresponsive to therapy

ALERT

H. pylori testing is NOT indicated in the evaluation of chronic abdominal pain, nonulcer dyspepsia, or newly diagnosed GERD unless the patient has endoscopically documented peptic ulcer disease, a family history of gastric cancer, documented mucosa-associated lymphoid tissue (MALT) lymphoma, or unexplained iron deficiency anemia.

- Radiologic evaluation (abdominal decubitus and upright films)
 - Dilatation or air–fluid levels: acute obstruction

- “Double bubble” sign and airless abdomen: midgut volvulus/malrotation
- Air–fluid level or fecalith in right lower quadrant: acute appendicitis if suspected
- Radiopaque renal stones or dilated ureters
- Upper gastrointestinal contrast study to document anatomic anomalies (i.e., malrotation)
- Ultrasound/CT scan in the evaluation of trauma, acute appendicitis, intussusception, suspected abscess in IBD, tumors, pancreatitis/pseudocyst, cholecystitis
- Use of CT scan in suspected acute appendicitis should be carefully considered, as it can both lead to unnecessary appendectomies or be falsely negative. In patients identified as “low risk” for appendicitis (absent leukocytosis with left shift), ultrasound and/or close observation should be considered as alternative to CT scan.

TREATMENT

GENERAL MEASURES

- In the acute setting of abdominal pain suggesting a potential life-threatening condition (acute appendicitis, acute obstruction, volvulus), the patient should be stabilized and referred appropriately for further management including surgery if indicated.
- In the setting of extraintestinal conditions (i.e., pneumonia, pharyngitis, or urinary tract infection), antibiotic therapy should be initiated if indicated.
- In the setting of chronic pain and in the absence of red flags (see “[Referral](#)”), the most likely diagnoses can be categorized as abdominal pain–related FGIDs. These include functional dyspepsia, IBS, abdominal migraine, and functional abdominal pain syndrome. The diagnosis of these entities is based on specific symptom based criteria (Rome III).

SURGERY/OTHER PROCEDURES

- Functional dyspepsia: trial of proton pump inhibitor (PPI) therapy for 4

weeks to rule out postviral dyspepsia. Avoid use of NSAIDs, spicy and fatty foods, and caffeine. If no response or unable to tolerate progressive taper of PPIs, refer to a gastroenterologist for endoscopic evaluation.

- Irritable bowel syndrome: address bowel pattern: diarrhea (antidiarrheals); constipation (nonstimulating laxatives); peppermint oil or antispasmodics may alleviate pain; probiotics
- Functional abdominal pain syndrome: Use biopsychosocial approach; behavioral treatment with or without trial of tricyclic antidepressants (particularly in presence of anxiety)

ALERT

Psychological comorbidities should be addressed in all FGIDs.

REFERRAL

- The presence of clinical red flags, in the setting of acute or chronic abdominal pain, may indicate an underlying mucosal pathology of the gastrointestinal tract (other than infectious), warranting referral to a gastroenterologist for further endoscopic evaluation and management. These include the following:
 - Nocturnal pain: pain that wakes from sleep
 - Persistent vomiting and/or dysphagia
 - GERD non responsive to PPI trial
 - Hematemesis
 - Nocturnal diarrhea
 - Hematochezia
 - Perianal disease
 - Weight loss/delayed growth and/or puberty
 - Family history of PUD or IBD

- R10.31 Right lower quadrant pain

ABNORMAL BLEEDING

Char Witmer

BASICS

DESCRIPTION

Abnormal bleeding may present as

- Frequent or significant mucocutaneous bleeding (epistaxis, bruising, gum bleeding, or menorrhagia)
- Bleeding in unusual sites such as muscles, joints, or internal organs
- Excessive postsurgical bleeding

ETIOLOGY

Abnormal bleeding can be the result of a coagulation factor deficiency, an acquired or congenital disorder of platelet number or function, or inherited or acquired collagen vascular disorders.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Platelet disorders may be quantitative or qualitative, collagen vascular disorders can be acquired or inherited, and disorders of coagulation factors can be congenital or acquired.

- Thrombocytopenia: defective production
 - Congenital/genetic
 - Thrombocytopenia with absent radii syndrome
 - Amegakaryocytic thrombocytopenia
 - Fanconi anemia
 - Metabolic disorders
 - Wiskott-Aldrich syndrome
 - Bernard-Soulier syndrome
 - Other rare familial syndromes (e.g., MYH9-related disorders, RUNX1 mutations)
 - Acquired

- Aplastic anemia
 - Drug-associated marrow suppression
 - Virus-associated marrow suppression
 - Chemotherapy
 - Radiation injury
 - Nutritional deficiencies (e.g., vitamin B₁₂ and folate)
- Marrow infiltration
 - Neoplasia (e.g., leukemia, solid tumor)
 - Histiocytosis
 - Osteopetrosis
 - Myelofibrosis
 - Hemophagocytic syndromes
 - Storage diseases
- Thrombocytopenia: increased destruction
 - Idiopathic thrombocytopenia
 - Neonatal alloimmune thrombocytopenia
 - Maternal autoimmune thrombocytopenia
 - Drug-induced (heparin, sulfonamides, digoxin, chloroquine)
 - Disseminated intravascular coagulation
 - Infection: viral, bacterial, fungal, rickettsial
 - Microangiopathic process (e.g., thrombotic thrombocytopenic purpura or hemolytic uremic syndrome)
 - Kasabach-Merritt syndrome
- Thrombocytopenia: sequestration
 - Hypersplenism
 - Hypothermia
- Platelet function disorders
 - Storage pool disorders (e.g., dense granule deficiency, Hermansky-Pudlak or Chediak-Higashi syndrome)
 - Platelet receptor abnormalities (e.g., Glanzmann thrombasthenia, adenosine 5'-diphosphate receptor defect)
 - Drugs (e.g., aspirin, NSAIDs, guaifenesin, antihistamines, phenothiazines, anticonvulsants)
 - Uremia
 - Paraproteinemia

- Coagulation disorders
 - Prolongation of activated partial thromboplastin time (aPTT)
 - Deficiency of factors VIII, IX, XI, or XII; prekallikrein; or high-molecular-weight kininogen
 - Acquired inhibitor or lupus anticoagulant
 - Prolongation of prothrombin time (PT)
 - Deficiency of factor VII
 - Mild vitamin K deficiency
 - Liver disease, mild to moderate
 - Prolongation of PT and aPTT
 - Liver disease, severe
 - Disseminated intravascular coagulation
 - Severe vitamin K deficiency
 - Hemorrhagic disease of the newborn
 - Deficiency of factors II, V, or X or fibrinogen
 - Dysfibrinogenemia
 - Hypoprothrombinemia associated with a lupus anticoagulant
 - Normal screening (PT, aPTT) laboratory tests
 - Von Willebrand disease
 - Factor XIII deficiency
 - Alpha-2-antiplasmin deficiency
 - Plasminogen activator inhibitor-I deficiency
- Vessel wall disorders
 - Congenital
 - Hereditary hemorrhagic telangiectasia
 - Ehlers-Danlos syndrome
 - Marfan syndrome
 - Acquired
 - Vasculitis (systemic lupus erythematosus, Henoch-Schönlein purpura, and others)
 - Scurvy (vitamin C deficiency)

ALERT

Always consider nonaccidental injury as a cause of increased bruising.

APPROACH TO PATIENT

- **Phase 1**
 - Includes a thorough history and physical exam
 - Familial history specifically of bleeding or consanguinity
 - Standard screening laboratory tests include PT, aPTT, and platelet count.
- **Phase 2**
 - If a bleeding disorder is suspected but the initial screening tests are negative, testing for von Willebrand disease, qualitative platelet disorders, dysfibrinogenemia, or factor XIII deficiency is warranted.
- **Phase 3**
 - Any abnormal screening tests need further evaluation with additional testing to define the specific disorder (e.g., factor assays).

HISTORY

By taking into account the patient's age, sex, clinical presentation, past medical history, and family history, the most likely cause of bleeding can be usually determined.

- Hemophilia is X-linked, most common in males.
- A family history of bleeding suggests an inherited bleeding disorder.
- Bleeding in unusual places without significant trauma (intracranial, joints) indicates a significant bleeding disorder.
- Persistent palpable bruising is highly suggestive of a bleeding disorder.
- Several surgeries without bleeding makes an inherited bleeding disorder less likely.
- Mucocutaneous bleeding (gum bleeding, bruises, epistaxis, recurrent petechiae, menorrhagia) may indicate thrombocytopenia, a platelet disorder, or von Willebrand disease.
- The use of aspirin and NSAIDs (e.g., ibuprofen) negatively affect platelet function and result in an acquired bleeding disorder.

PHYSICAL EXAM

- Children with bleeding disorders are more likely to have large bruises (>5 cm), palpable bruises, and bruises on more than one body part.
- Uncommon sites for bruising for all ages include the back, buttocks, arms, and abdomen.
- **Finding:** Petechiae in skin and mucous membranes?

- Significance: Disorder of platelet number or function, von Willebrand disease, or vasculitis
- **Finding:** Bruises in unusual places?
- Significance: Possible platelet disorder or von Willebrand disease
- **Finding:** Large bruises or palpable bruises?
- Significance: Coagulation deficiencies, severe platelet disorders, or von Willebrand disease
- **Finding:** Delayed wound healing?
- Significance: Factor XIII deficiency or dysfibrinogenemia
- **Finding:** Purpura localized to lower body (buttocks, legs, ankles)?
- Significance: Henoch-Schönlein purpura

DIAGNOSTIC TESTS & INTERPRETATION

- The aPTT may be extremely prolonged in patients with deficiencies of the contact factors (prekallikrein, high molecular weight kininogen, factor XII). These deficiencies do not result in bleeding.
- Improper specimen collection including heparin contamination or underfilling of the specimen tube can result in artificially prolonged clotting times.
- **Test:** Phase 1: initial laboratory screening
 - Platelet count
 - PT and aPTT
- **Test:** Phase 2
- Test for von Willebrand disease
 - Factor VIII:C
 - Von Willebrand factor antigen (VIIR:Ag)
 - Von Willebrand factor activity (ristocetin cofactor)
 - Von Willebrand factor multimeric analysis—only send after the diagnosis of von Willebrand disease has been established
 - Thrombin time and fibrinogen assay to screen for afibrinogenemia and dysfibrinogenemia
 - Definitive platelet testing includes platelet aggregation and secretion studies with specific agonists.
 - Factor XIII deficiency suspected: factor XIII assay (Urea clot lysis study is a screening test.)
- **Test:** Phase 3: discriminating laboratory studies for abnormal phase 1

or 2 tests

- When thrombocytopenia is present:
 - Inspection of blood smear
 - Mean platelet volume (may be normal or elevated in destructive causes, elevated in congenital macrothrombocytopenias, low in Wiskott-Aldrich syndrome)
 - Bone marrow aspiration (rarely necessary)
- Prolonged aPTT
 - Inhibitor screen (50:50 mixing study of patient's and normal plasma)
 - If aPTT fully corrects with mixing, this is consistent with a factor deficiency:
 - Assess for specific factor deficiencies: factors VIII, IX, XI, or XII; prekallikrein; and high-molecular-weight kininogen
 - If partial or no correction after mixing study:
 - Inhibitor is present.
 - Confirmatory test for the presence of a lupus anticoagulant with a platelet-neutralizing procedure or dilute Russel viper venom time (DRVVT)
- Prolonged PT
 - Inhibitor screen should also be considered for prolonged PT.
 - Specific factor level (VII)
- Prolonged PT and aPTT
 - Factor assays: II (prothrombin), V, X, and fibrinogen
 - Potential other causes: disseminated intravascular coagulation, liver disease, and fibrinogen disorders, as described previously
 - Vitamin K deficiency, moderate to severe

ALERT

Pitfalls of testing:

- **PFA-100**
 - Low specificity and sensitivity
 - Affected by medications (NSAIDs)
 - Not recommended as a screening test
- **Bleeding time**
 - Prolonged when platelets $<100,000/\text{mm}^3$

- Affected by medications such as aspirin, NSAIDs, antihistamines
- Does not correlate with bleeding risk
- Highly operator dependent
- Not recommended as a screening test
- **PT and aPTT**
 - Normal ranges are age-dependent.
 - Polycythemia (hematocrit 65%) or underfilling of the specimen tube may result in a spuriously prolonged result.
 - Heparin contamination results in a spuriously prolonged result.
- **Von Willebrand disease studies**
 - Values fluctuate over time and may be periodically normal in affected individuals.
 - May require repeated testing to make diagnosis

EMERGENCY CARE

- Pressure, elevation, and ice are generally helpful for most bleeding disorders when active bleeding is present.
- More definitive care is dictated by the nature of the underlying hemostatic defect:
 - Platelet transfusions are useful in disorders of thrombocytopenia owing to decreased production and for intrinsic qualitative platelet disorders but not for immune platelet disorders.
 - Frozen plasma should be used only in severe cases when the exact diagnosis is not readily available but a defect in coagulation is suspected.
- Head injuries in patients with thrombocytopenia or hemophilia require immediate medical attention.

TREATMENT

GENERAL MEASURES

- Pressure on wound
- Elevation
- Topical application of thrombin
- Topical application of clot-activating polymers

CODES

ICD10

- D68.9 Coagulation defect, unspecified
- R04.0 Epistaxis
- T14.8 Other injury of unspecified body region

FAQ

- Q: What are the proper preoperative screening tests for bleeding disorders prior to elective surgery such as tonsillectomy?
- A: A thorough personal history, familial history, and physical exam are by far the most important screening tests. A bleeding time or PFA-100 is not recommended. A CBC, PT, and aPTT are often requested by the surgeon, but normal results do not ensure that a bleeding complication will not occur. Overall, the sensitivity and specificity of these screening tests is poor.
- Q: Bruising is a normal part of childhood. How does one know when bruising is “too much”?
- A: Small bruises on bony prominences on the front of the body are common in children and probably reflect trauma rather than a bleeding disorder. Children with bleeding disorders are more likely to have

large bruises (>5 cm), palpable (raised) bruises, and bruises on more than one body part. Uncommon sites for bruising for all ages include the back, buttocks, arms, and abdomen

ACETAMINOPHEN POISONING

Kevin C. Osterhoudt

BASICS

DESCRIPTION

- Acetaminophen poisoning may occur after acute or chronic overdose.
- Acetaminophen is sold under many brand names and is often an ingredient in combination pain reliever preparations.
- Acetaminophen poisoning may be clinically occult until frank hepatic or renal injury become evident.
- After acute overdose, a serum acetaminophen level above the treatment line of the Rumack-Matthew acetaminophen poisoning nomogram should be considered possibly hepatotoxic.
- Serious hepatotoxicity after a single acute exploratory ingestion by young children is rare compared with that from intentional overdose by adolescents.
- Most toddlers with acetaminophen hepatotoxicity suffer repeated supratherapeutic dosing.

EPIDEMIOLOGY

- Analgesics are the most common drugs implicated in poisoning exposures reported to U.S. poison control centers.
- Acetaminophen preparations make up ~45% of all analgesic poisoning exposures reported to poison control centers.

Incidence

Acetaminophen poisoning is the most common cause of acute liver failure in the United States.

RISK FACTORS

- Depression
- Pain syndromes
- Glutathione depletion: prolonged vomiting, alcoholism, etc.
- CYP2E1 induction: alcoholism, isoniazid therapy, etc.

GENERAL PREVENTION

- Acetaminophen should be stored with child-resistant caps, out of sight of young children.
- Proper use of acetaminophen products should be taught to patients with pain or fever.

PATHOPHYSIOLOGY

- Most absorbed acetaminophen is metabolized through formation of hepatic glucuronide and sulfate conjugates.
- Some acetaminophen is metabolized by the CYP450 mixed-function oxidase system, leading to the formation of the toxic N-acetyl-p-benzoquinoneimine (NAPQI).
- NAPQI is quickly detoxified by glutathione under usual circumstances.
- After overdose, metabolic detoxification can become saturated:
 - Drug elimination half-life becomes prolonged.
 - Proportionately more NAPQI is produced.
 - Glutathione supply cannot meet detoxification demand.
 - Hepatic or renal toxicity may ensue.

ETIOLOGY

- Single acute overdose of >150 mg/kg or 10 g
- Repeated overdose of >100 mg/kg/day or 6 g/day, for >2 days

COMMONLY ASSOCIATED CONDITIONS

- Acetaminophen is often marketed in combination with other pharmaceuticals, which may complicate a drug overdose situation.
- Adolescents frequently overdose on more than 1 drug preparation.

DIAGNOSIS

HISTORY

- Medical history of pain or fever
 - Acetaminophen ingestion should be explored in any patient being treated for pain or fever.
- Amount of acetaminophen ingested
 - A single, acute ingestion of <150 mg/kg (\leq 10 g in adolescents) is

unlikely to cause significant toxicity among otherwise healthy individuals.

- Timing of ingestion
 - Allows application of the Rumack-Matthew nomogram
- Sustained-release preparation
 - Acetaminophen is now available in sustained-release form.
- Medication list
 - Use of isoniazid or other CYP2E1 hepatic enzyme inducers may increase risk for toxicity.
- Signs and symptoms
 - Initially may be clinically silent
 - Vomiting
 - Anorexia

PHYSICAL EXAM

Right upper quadrant tenderness may suggest acetaminophen-induced hepatitis.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Serum acetaminophen level
 - Allows application of the Rumack-Matthew nomogram after acute overdose
 - Rumack-Matthew nomogram applies only to single, acute acetaminophen overdose scenarios.
- Hepatic transaminases
 - Aspartate aminotransferase (AST) is the most sensitive of the widely available measures to assess acetaminophen hepatotoxicity and begins to rise 12–24 hours after significant overdose.
- Liver and kidney function tests
 - As the AST rises, it is important to follow liver and kidney function with tests such as serum glucose, prothrombin (PT) and partial thromboplastin (PTT) times, serum creatinine, plasma pH, and serum albumin.
 - The PT and PTT may be slightly elevated owing to direct effect of elevated blood acetaminophen concentrations or N-acetylcysteine

therapy, without signifying liver injury.

- The decline of an elevated serum AST may indicate either liver recovery or profound liver failure and must be interpreted in context.
- Salicylate level
 - May be a coingestant in the setting of analgesic drug overdose

Pathologic Findings

Hepatic zone III (centrilobular) necrosis

DIFFERENTIAL DIAGNOSIS

- Infectious hepatitis
- Other drug-induced hepatitis

TREATMENT

MEDICATION

First Line

- Single acute overdose
 - Activated charcoal, 1–2 g/kg (maximum 75 g), may be administered if acetaminophen is judged to be present in the stomach or proximal intestine (usually within 1 hour of ingestion).
 - N-acetylcysteine should be administered if a serum acetaminophen level obtained >4 hours after overdose falls above the treatment line of the Rumack-Matthew nomogram (see [Appendix, Figure 4](#)).
 - Patients presenting to medical care >7 hours after overdose should be given a loading dose of N-acetylcysteine while waiting for the serum acetaminophen level result.
 - Oral N-acetylcysteine dose: 140 mg/kg loading dose, followed by 70 mg/kg maintenance doses q4h (see “[FAQ](#)”)
 - Intravenous N-acetylcysteine dose: 150 mg/kg loading dose over 1 hour, then 12.5 mg/kg/h for 4 hours, then 6.25 mg/kg/h (see “[FAQ](#)”)

ALERT

Some toxicologists suggest higher dosing for very large acetaminophen

overdoses.

- Repeated supratherapeutic ingestion
 - Consider N-acetylcysteine therapy if
 - Ingestion of >100 mg/kg or 6 g/day for consecutive days
 - Patient is symptomatic
 - AST level is elevated
 - Acetaminophen level is higher than would be expected given dosing, and AST level is normal
- Once started, N-acetylcysteine therapy should be continued until
 - The serum acetaminophen level is nondetectable
 - A simultaneous serum AST has not risen or, if elevated, liver enzymes and liver function are clearly improving

Second Line

- Acetaminophen poisoning and oral N-acetylcysteine therapy are emetogenic: chill and cover the N-acetylcysteine. Consider antiemetic therapy with drugs such as metoclopramide and/or ondansetron. Enteral N-acetylcysteine may be given slowly via nasogastric or nasoduodenal tube.
- Intravenous N-acetylcysteine has been associated with anaphylactoid reactions, which may require cessation or slowing of infusion, antihistamines, corticosteroids, and/or epinephrine.

ADDITIONAL TREATMENT

General Measures

Evaluate for possible polypharmacy overdose.

ISSUES FOR REFERRAL

- Patients with AST approaching 1,000 IU/L should be considered for transfer to a liver transplant center.
- Mental health services should be provided to victims of intentional overdose.

SURGERY/OTHER PROCEDURES

Liver transplant should be considered per transplant center protocols. The King's College Hospital Criteria include the following:

- pH <7.30 after resuscitation, or

- PT >1.8 times control, plus
- Serum creatinine >3.3 mg/dL, plus
- Encephalopathy

INPATIENT CONSIDERATIONS

Admission Criteria

- N-acetylcysteine therapy
- Psychiatric evaluation warranted

Discharge Criteria

- N-acetylcysteine therapy concluded
- No concern for developing liver injury

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Cardiorespiratory monitoring is warranted during intravenous N-acetylcysteine therapy.
- Intensive care monitoring is warranted during fulminant hepatic failure.

PATIENT EDUCATION

- Drug administration education should be offered to victims of chronic overdose.
- Home safety education should be provided after pediatric exploratory ingestions.

PROGNOSIS

- Among previously healthy children, hepatotoxicity is rare with single doses <150–200 mg/kg.
- After single acute acetaminophen overdose, likelihood of hepatotoxicity may be determined by using the Rumack-Matthew nomogram.
- N-acetylcysteine therapy prevents hepatic failure in >99% of acetaminophen-poisoned patients if administered within 8 hours of overdose.

- N-acetylcysteine therapy is less efficacious when administered >8 hours after overdose but should still be offered.
- Repetitive dosing of acetaminophen >75 mg/kg/day should be evaluated cautiously, especially in the presence of the following:
 - Febrile illness
 - Vomiting or malnourishment
 - Anticonvulsant or isoniazid therapy

COMPLICATIONS

- Hepatic failure
- Renal insufficiency
- Anaphylactoid shock may complicate intravenous N-acetylcysteine therapy.

CODES

ICD10

- T39.1X4A Poisoning by 4-Aminophenol derivatives, undetermined, init
- K71.9 Toxic liver disease, unspecified
- T39.1X1A Poisoning by 4-Aminophenol derivatives, accidental, init

FAQ

- Q: What is “patient-tailored” N-acetylcysteine (NAC) therapy?
- A: The duration of N-acetylcysteine therapy used to depend on the pharmaceutical form administered but is now tailored to the patient based on serum acetaminophen level and liver function.
- Q: Should NAC be given PO or IV?
- A: Both seem to be similarly efficacious. Oral administration of NAC is complicated by taste aversion and vomiting. IV NAC may lead to anaphylactoid shock. Few cost–benefit studies are available for direct comparison of patient-tailored courses of oral NAC and IV NAC.

ACNE

Deepti Gupta • Renee Howard

BASICS

DESCRIPTION

Acne vulgaris is one of the most common skin conditions in children and adolescents. It is a disorder of pilosebaceous units (PSUs). PSUs are found predominantly on the face, chest, back, and upper arms. Acne presents as comedonal or inflammatory lesions and can cause depressed scars and hyperpigmentation. Presentation, treatment, and associated systemic manifestations differ by age of presentation, pubertal status, and severity of disease.

- Classification of acne by age:
 - Neonatal (birth to 6 weeks): affects up to 20% of neonates. Also known as neonatal cephalic pustulosis. Presents with a papulopustular eruption predominantly on face. Thought to be due to *Malassezia* colonization. No treatment necessary. For severe cases can use ketoconazole cream 2%.
 - Infantile acne (6 weeks to 1 year): presents with comedonal and inflammatory lesions on face. Some evidence that it may predispose to severe adolescent acne. Often, no underlying endocrine abnormality. Self-limited but in severe cases can use topical acne treatments
 - Midchildhood acne (1–6 years): uncommon. Presents with comedonal and inflammatory lesions on face. Suspect an underlying endocrinopathy.
 - Preadolescent (7–11 years): presents with predominantly comedonal lesions in “T-zone,” central face. Can be first sign of onset of puberty
 - Adolescent (12–19 years): very common presentation, affects 85% of adolescents

RISK FACTORS

Genetics

Familial patterns exist, but no inheritance pattern has been demonstrated.

GENERAL PREVENTION

- Effective and early treatment limits scarring, postinflammatory pigment alteration, and minimizes psychosocial impact.
- Use of noncomedogenic moisturizers and sunscreens

PATHOPHYSIOLOGY

Pathogenesis of acne is multifactorial and involves 4 different components:

- Increased sebum production: stimulated by an increase in androgen levels. The adrenal gland is active during the 1st year of life and then reawakens in preadolescent time period. Production peaks in teens and decreases in the 20s.
- Alteration in follicular growth and differentiation leading to the creation of a microcomedone, a precursor of inflammatory and comedonal acne lesions
- Follicular colonization with *Propionibacterium acnes*, an anaerobic, gram-positive diphtheroid bacteria. *P. acnes* produces free fatty acids (FFAs) leading to inflammation.
 - Inflammation and immune response through the innate immune system

ETIOLOGY

- Androgen excess (physiologic vs. pathologic)
- Medication-induced (corticosteroids, anticonvulsants, lithium, etc.)
- Occlusion (from topical- or oil-based products)
- Friction from athletic helmets, shoulder pads, chin straps, or bra straps may worsen acne.

COMMONLY ASSOCIATED CONDITIONS

- Polycystic ovarian syndrome (PCOS)
- SAPHO syndrome: synovitis, acne, pustulosis, hyperostosis, and osteitis
- Adrenal or gonadal/ovarian tumors
- Late-onset congenital adrenal hyperplasia

DIAGNOSIS

HISTORY

- Age of onset: Early or late onset of acne may indicate androgen excess.
- Medications and supplement use (including some OCPs, progestin implants, depot medroxyprogesterone, steroids (topical, inhaled, or oral), anticonvulsants, lithium, isoniazid, nicotine products) may worsen acne.
- Menstrual history: Premenstrual flares may occur due to androgenic effects of progesterone.
- Androgen excess (history of or current)
 - Prepubertal: early-onset acne or body odor, increased linear growth, axillary or pubic hair, genital maturation, or clitoromegaly
 - Postpubertal: alopecia, hirsutism, truncal obesity, acanthosis nigricans, irregular menses, increased muscle mass
- Previous treatments tried and reason failed (cost, adherence, tolerability, ease of use).

ALERT

Psychological impact: Ask patients about self-esteem, depression, and suicidal ideations.

PHYSICAL EXAM

- Skin
 - Distribution of lesions
 - Type of acne lesions: comedonal (open: blackhead, due to oxidation of lipids and not dirt; closed: whitehead), inflammatory (erythematous papule, pustule, nodule, pseudocyst)
 - Scarring and hyperpigmentation
- Global assessment of acne severity (number, size, extent, and scarring)
- Note signs of androgen excess (see “[History](#)”).
- Height, weight, growth curve
- Blood pressure

DIAGNOSTIC TESTS & INTERPRETATION

Lab/Imaging

- Consider for patients with signs of androgen excess, midchildhood acne, or acne unresponsive to traditional therapy.
 - Serologic testing (LH, FSH, testosterone total and free, DHEA-S, androstenedione prolactin, 17-hydroxyprogesterone)
 - Bone age
 - Referral to pediatric endocrinology
 - Imaging for adrenal or gonadal tumor
- Lab monitoring while using isotretinoin should include baseline and monthly complete blood count, fasting lipid panel (triglycerides and cholesterol), transaminases, and pregnancy test for females. Prior to starting females need two negative pregnancy tests 1 month apart.

DIFFERENTIAL DIAGNOSIS

- Adenoma sebaceum (facial angiofibromas)
- Keratosis pilaris
- Flat warts
- Molluscum contagiosum
- Periorificial dermatitis
- Milia
- Miliaria
- Syringomas
- Demodex folliculitis
- Malassezia (Pityrosporum) folliculitis
- Gram-negative folliculitis
- Staphylococcal folliculitis
- Chloracne (exposure to chlorinated aromatic hydrocarbons)
- Papular sarcoidosis

TREATMENT

- Choose regimen based on previous therapies, cost, vehicle selection, regimen complexity, active scarring, and psychosocial impact.
- Vehicle selection:
 - Creams and lotions less drying than gels and solutions
 - Creams better for sensitive skin/eczema

- Gels and solutions may be better for oily skin or for make-up application.
- Manage patient expectations.
- Treatment may take 2–3 months to be effective.
- Acne may initially flare prior to improving.
- Counsel about medication side effects.

GENERAL APPROACH

Categorized by acne severity and age of patient.

- Mild acne: comedonal, inflammatory, or mixed
 - Initial:
 - Topical monotherapy:
 - Benzoyl peroxide (BP)
 - Topical retinoid
 - Topical combination therapy:
 - BP + antibiotic
 - Retinoid + BP
 - Retinoid + BP + antibiotic
 - Inadequate response:
 - Assess adherence.
 - Add BP or retinoid if not already prescribed.
 - Change:
 - Topical retinoid concentration, type, or formulation
 - Change topical combination therapy.
- Moderate acne: comedonal, inflammatory, or mixed
 - Initial:
 - Topical combination therapy:
 - Retinoid + BP
 - Retinoid + BP + antibiotic
 - Oral antibiotic + topical retinoid + BP
 - Inadequate response:
 - Assess adherence.
 - Change topical retinoid concentration, type, or formulation.
 - Add or change oral antibiotic.
 - Females: consider hormonal therapy.
 - Consider oral isotretinoin.

- Consider dermatology referral.
- Severe acne: inflammatory, mixed, and/or nodular lesions. Extensive involvement often with significant scarring
 - Initial:
 - Oral antibiotic + topical retinoid + BP ± topical antibiotic
 - Consider dermatology referral.
 - Inadequate response:
 - Assess adherence.
 - Change topical retinoid concentration, type, or formulation.
 - Change oral antibiotic
 - Females: Consider hormonal therapy.
 - Consider oral isotretinoin.
 - Scars warrant aggressive treatment targeting inflammation.

MEDICATION (DRUGS)

- Topical agents/over the counter
 - Gentle cleansers:
 - Use gentle soap free, pH-balanced cleansers are recommended for everyday washing.
 - Benzoyl peroxide (BP):
 - Bactericidal, mild comedolytic, and anti-inflammatory properties.
 - Limits antibiotic resistance and provides increased efficacy in combination with retinoids
 - Available as lotion, cream, wash, and gel in 2.5–10%
 - Increased concentration does not increase efficacy but can cause more irritation.
 - 5% concentration generally effective. Can start with lower concentration or decrease number of days of use if too irritating
 - Side effects: drying, erythema, burning, peeling, stinging, and rarely contact dermatitis
 - Cautions: can cause bleaching of hair, clothing, and linen; increased risk of photosensitivity. Rare but serious and potentially life-threatening allergic reactions or severe irritation have been reported.
 - Salicylic acid (SA):
 - Promotes comedolysis with drying and peeling

- Not as effective as BP
- Sulfur/sulfacetamide:
 - Mild antibacterial and keratolytic properties
 - Very well-tolerated
 - Distinctive odor

ALERT

Avoid vigorous cleansing of the skin or harsh facial astringents and toners that may irritate the skin.

- Prescription topical medications
 - Topical antibiotics (erythromycin, clindamycin):
 - Reduce *P. acnes* concentration and inflammatory mediators
 - Available in combination products to increase compliance, but these products are often more expensive
 - Combine with BP to decrease antibiotic resistance.
 - Combine with retinoids to help yield faster results.
 - Side effects: well-tolerated but may include drying or irritation
 - Topical retinoids:
 - Prevent formation of microcomedones, clear existing microcomedones, anti-inflammatory
 - Available in 3 forms
 - Adapalene
 - Available as cream, gel, lotion. Also as a combination product with BP
 - Pregnancy class C (see [Appendix 4; Table 10](#))
 - Photostable
 - Better tolerability than tretinoin
 - Tretinoin
 - Available as cream, gel, microsphere gel of various strengths
 - Pregnancy class C (see [Appendix 4; Table 10](#))
 - Apply to dry skin.
 - Can be very irritating and drying
 - Start with 0.025%, low strength only a few times a week, and titrate up.
 - Inactivated by sunlight, use at nighttime.

ALERT

BP inactivates tretinoin when used together. Apply BP in the morning and tretinoin at night.

- Tazarotene
 - Available in cream and gel
 - Pregnancy class X; contraindicated in pregnancy
 - Apply to dry skin.
 - More irritating than other retinoids
 - Inactivated by sunlight, use at nighttime.
- 1st-line therapy for most patients
- Side effects: erythema, dryness, irritation, initially acne flares, and photosensitivity (advise use of daily noncomedogenic sunscreen with SPF 30+ and facial moisturizer applied before tazarotene).
- Apply at night, as medication is inactivated by sunlight.
- Apply pea-sized amount to entire face.
- Start with lowest strength three times a week, and increase frequency slowly to every night as tolerated. Some patients may not tolerate medication every night. Increase concentration of medication if patient still with oily skin or getting new acne lesions.
- Azelaic acid:
 - Comedolytic and antibacterial; decreases hyperpigmentation
 - 15% gel or 20% cream, applied twice daily.
 - Pregnancy class B (see [Appendix 4; Table 10](#))
 - Side effects include itching, burning, tingling, stinging, and erythema.
 - Consider for patients with comedonal acne who cannot use retinoids.
- Topical dapsone:
 - Synthetic sulfone has antimicrobial and anti-inflammatory effects.
 - Available in 5% gel, twice daily application recommended
 - Most effective against inflammatory acne lesions
 - Safe in patients with G6PD deficiency and with sulfonamide

allergy

- ▢ Enhanced efficacy when combined with retinoids
- ▢ Side effects: erythema and dryness
- ▢ Caution: When used with BP, a temporary orange staining of skin can occur.

ALERT

Do not use antibiotics as monotherapy due to slow onset of action and development of antibiotic resistance. Use with BP.

- Oral antibiotics: reduce *P. acnes* concentration and inflammatory mediators
 - Tetracyclines (doxycycline, minocycline, tetracycline): pregnancy class D. Must be >8 years of age due to staining of tooth enamel
 - ▢ Doxycycline and minocycline are preferred due to 1–2×/day dosing and greater follicular penetration.
 - Dosing: 50–100 mg daily or b.i.d.
 - ▢ Tetracycline is cheap but has least efficacy.
 - ▢ Increasing antibiotic resistance. Limit treatment length and do not use as monotherapy. Use with BP or topical retinoid.
 - ▢ Taper or switch to topical retinoid monotherapy after 12 weeks and when patient is no longer getting new acne lesions.
 - ▢ Systemic side effects and cautions:
 - Doxycycline: GI upset, vaginal candidiasis, pill esophagitis, photosensitivity (phototoxicity), benign intracranial hypertension. Take with food and large glass of water, stay upright 1 hour after taking medication, photoprotection, can use enteric-coated form.
 - Minocycline: acute vestibular reaction (vertigo, dizziness), vaginal candidiasis, hyperpigmentation, drug hypersensitivity reaction 2–8 weeks after starting medication, lupuslike syndrome, Stevens-Johnson syndrome (SJS), benign intracranial hypertension
 - Sulfa (trimethoprim-sulfamethoxazole):
 - ▢ Dosing: 160–800 mg PO b.i.d.
 - ▢ Used judiciously, refractory cases

- Systemic side effects: severe cutaneous reactions (SJS, toxic epidermal necrolysis, drug hypersensitivity reaction, fixed drug eruption), bone marrow suppression
 - Check baseline CBC and periodically thereafter.
- Cephalosporins (cephalexin, cefadroxil):
 - Dosing: 500 mg PO b.i.d.
 - Well-tolerated
 - Systemic side effects: GI upset
- Penicillins (amoxicillin):
 - Well-tolerated
 - Systemic side effects: GI upset
- Macrolides (erythromycin, azithromycin)
 - High prevalence of *P. acnes* resistance to erythromycin
 - Systemic side effects: erythromycin: GI upset, drug–drug interaction
- Oral retinoids (isotretinoin): decreases sebum production, is anti-inflammatory, and reduces *P. acnes*.
 - Used as monotherapy
 - Used for recalcitrant acne or with significant scarring, given side effects
 - Dosing:
 - Start with 0.5 mg/kg/day for first 4 weeks and then advance to 1 mg/kg/day.
 - Goal cumulative treatment course is 120–150 mg/kg.
 - For patients with severely inflamed acne, start at lower dose to prevent initial acne flares or pretreat with oral corticosteroids.
 - Need baseline and monthly labs (see “[Lab/Imaging](#)”)
 - Side effects:
 - Common: dry skin, dry eyes, cheilitis, myalgias
 - Teratogen
 - 2 forms of birth control need to be used while on medication.
 - FDA-mandated registry (iPledge: see <https://www.ipledgeprogram.com/>). Prescribed only by registered users
 - Depression and suicide have been reported in patients on

isotretinoin (causality not established, but counsel about this risk).

- ▣ IBD: conflicting data. Association may exist, but rare, and there are many confounding factors.
- ▣ Bone effects: conflicting data regarding increased risk of fractures and demineralization. Hyperostoses and premature epiphyseal closure are rare and uncommon side effects.
- ▣ Rare, sporadic reports of serious skin infections including erythema multiforme, Stevens-Johnson syndrome, and toxic epidermal necrolysis

ALERT

Do not use tetracycline antibiotics with oral retinoids due to risk of pseudotumor cerebri.

- Hormonal therapy: 2nd-line therapy for women. Usually used in combination with other acne treatments
 - OCPs (for women): Suppress ovarian androgen production.
 - Can be used as an adjunct for females with moderate to severe acne not responding to topical retinoids
 - 3 OCPs are FDA-approved for acne:
 - ▣ Ethinyl estradiol (35 mcg) and norgestimate (≥ 15 years of age)
 - ▣ Ethinyl estradiol (20–30–35 mcg) and norethindrone (≥ 15 years of age)
 - ▣ Ethinyl estradiol (30 mcg) and drospirenone (3 mg) (≥ 14 years of age)
 - Screen for personal tobacco use and family history of thromboembolic event.
 - ▣ Use caution in girls who smoke tobacco.
 - May need 3–6 months to see improvement
 - Side effects include nausea, breast tenderness, headache, weight gain, breakthrough menstrual bleeding, myocardial infarction, ischemic stroke, and DVTs.
 - Controversial effect on bone density and growth. Recommendation to start at least 1 year after onset of menstruation
- Spironolactone (for women): Blocks androgen receptor in sebaceous

gland

- Give 50–150 mg daily.
- Off-label use can be used in combination with OCP.
- Teratogenic effect must be on oral contraceptive.

COMPLEMENTARY & ALTERNATIVE THERAPIES

- Limited empiric studies on CAM and acne.
- RCTs of the following showed that they were not as effective as 5% BP but resulted in less skin irritation:
 - Tea tree oil: a mixture of terpenes and alcohols with antibiotic and antifungal properties; 5% solution may be effective in treating comedonal and inflammatory acne; may be associated with male gynecomastia
 - Gluconolactone 14% solution may be effective on comedonal and inflammatory acne.

ONGOING CARE

PATIENT EDUCATION

- <http://www.aad.org/dermatology-a-to-z/diseases-and-treatments/a-d/acne>
- <http://www.nlm.nih.gov/medlineplus/acne.html> (handout in Spanish also available)

COMPLICATIONS

- Scarring may be permanent.
- Hyperpigmentation: occurs more in dark-skinned individuals. Self resolves but may take months to years
- Self-esteem: Acne severity correlated to social variables including embarrassment and lack of enjoyment in social activities among teenagers.
- Patients with mild to moderate acne showed clinical depression and >5% suicidal ideation. Depression scores improve in correlation with response to acne treatment.

CODES

ICD10

- L70.9 Acne, unspecified
- L70.4 Infantile acne
- L70.0 Acne vulgaris

FAQ

- Q: Can I modify my diet to improve my acne?
- A: No. Specific dietary modifications are recommended, but there has been limited data that low glycemic diets may be correlated with improvement in acne.
- Q: Does poor hygiene cause acne?
- A: No. Use of harsh astringents, exfoliating scrubs, and vigorous scrubbing can worsen acne by causing more inflammation and scarring. They also can be more irritating and drying, decreasing tolerability of acne treatments. Recommend use of a gentle, soap free,

pH-balanced cleanser for daily use in addition to noncomedogenic moisturizers and sunscreen in conjunction with acne treatments.

- Q: Do cosmetics worsen acne?
- A: Recommend use of oil free, noncomedogenic make-up, which have been proven not to delay treatment response or worsen acne severity.

ACQUIRED HYPOTHYROIDISM

Adda Grimberg

BASICS

DESCRIPTION

Hypothyroidism that occurs after the neonatal period

EPIDEMIOLOGY

- May develop at any age
- Autoimmune thyroid disorders occur more frequently in children and adolescents with type 1 diabetes and other autoimmune conditions.
- Chronic lymphocytic thyroiditis prevalence correlates with iodine intake; countries with the highest dietary iodine also have the highest prevalence.

RISK FACTORS

Genetics

- Family history of thyroid disease or other autoimmune endocrinopathies increases risk.
- Genetic predisposition in patients with chronic lymphocytic thyroiditis; 30–40% of patients have a family history of thyroid disease, and up to 50% of their 1st-degree relatives have thyroid antibodies.
- Weak associations of chronic lymphocytic thyroiditis with certain human leukocyte antigen haplotypes; also associated with genotypes of cytotoxic T lymphocyte–associated 4 (CTLA4) and interleukin-18 (IL-18) genes.
- Autoimmune thyroid disease may be part of Schmidt syndrome (type II polyglandular autoimmune disease).
- Genetic syndromes associated with higher incidence of autoimmune thyroiditis:
 - Down syndrome
 - Turner syndrome (especially those with isochromosome Xq)

ETIOLOGY

- Myriad causes (see “[Differential Diagnosis](#)”)
- Can result from thyroid gland dysfunction (primary hypothyroidism) or from pituitary/hypothalamic dysfunction leading to understimulation of the thyroid gland (secondary and tertiary hypothyroidism)

COMMONLY ASSOCIATED CONDITIONS

- Vitiligo
- Alopecia areata
- Pernicious anemia
- Other autoimmune conditions

DIAGNOSIS

HISTORY

- Linear growth failure can be the first sign of thyroid dysfunction.
- Declining school performance is a sensitive marker for lethargy and reduced focus.
- Radiation exposure, history of type 1 diabetes, family history of other autoimmune disorders
- Signs and symptoms:
 - Early primary hypothyroidism can be asymptomatic.
 - Hypothyroid-related symptoms indicate progression from compensated to uncompensated hypothyroidism.
 - Hypothyroidism may be preceded in some cases by temporary hyperthyroidism (Hashitoxicosis).
 - Goiter may be the presenting sign of acquired hypothyroidism; tenderness suggests an infectious process.

PHYSICAL EXAM

- Bradycardia: Thyroid hormone has cardiac effects.
- Short stature (or fall-off on growth curve) and increased upper/lower segment ratio: Euthyroidism is required to maintain normal growth.
- Goiter: Note consistency, symmetry, nodularity, signs of inflammation:
 - May give a clue regarding cause of hypothyroidism
 - May provide a clinical marker to follow during therapy
- Myxedema (water retention) is not limited to subcutaneous tissue; it

may also lead to cardiac failure, pleural effusions, and coma.

- Muscle hypertrophy, yet muscle weakness
 - Most obvious in arms, legs, and tongue
 - Hypothyroidism causes disordered muscle function.
- Delayed relaxation phase of deep tendon reflexes due to slowed muscle contraction
- Pale, cool, dry, carotenemic (yellow-colored) skin due to decreased cell turnover
- Increase in lanugo hair in children; can be reversed with treatment
- Sexual development is an important factor. Hypothyroidism may be associated with either
 - Delayed puberty (due to low thyroid hormone level)
 - Precocious puberty and galactorrhea (due to elevated TSH)

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- T_4 (low) and TSH (elevated): Elevated TSH with normal T_4 indicates compensated (subclinical) primary hypothyroidism.
- Free T_4 : The most sensitive marker for secondary/tertiary hypothyroidism (TSH elevation lost; total T_4 may still be low normal)
- Thyroglobulin antibodies and thyroid peroxidase (microsomal) antibodies are markers for chronic lymphocytic thyroiditis.
- The following conditions may test false-positive for acquired hypothyroidism:
 - Thyroid-binding globulin deficiency: low total T_4 but normal free T_4 and TSH
 - Peripheral resistance to thyroid hormone: normal/high total T_4
 - “Euthyroid sick” syndrome: low T_4 and T_3 ; normal/low TSH; increased shunting to reverse T_3
- The following tests may be affected in acquired hypothyroidism:
 - Serum creatinine: elevated due to reduced glomerular filtration rate
 - LDL cholesterol level: elevated due to decreased LDL receptor expression
 - Creatine kinase: increased; hypothyroidism is a rare cause of rhabdomyolysis.

Imaging

Head MRI for cases of suspected secondary/tertiary hypothyroidism or pituitary or hypothalamic lesion

DIFFERENTIAL DIAGNOSIS

- Immunologic
 - Chronic lymphocytic thyroiditis (Hashimoto thyroiditis)
 - Polyglandular autoimmune syndrome (Schmidt syndrome)
- Infectious
 - Postviral subacute thyroiditis
 - Associated with congenital infections
 - Rubella
 - Toxoplasmosis
- Environmental
 - Goitrogen ingestion
 - Iodides
 - Expectorants
 - Thioureas
- Iatrogenic
 - Following surgical thyroidectomy for thyroid cancer, hyperthyroidism, or extensive neck tumors
 - Following radioiodine ablative therapy for hyperthyroidism or thyroid cancer
 - Following head or neck irradiation for cancer treatment
 - Medications: lithium, amiodarone, iodine contrast dyes, tiratricol (an OTC fat-loss supplement)
- Metabolic
 - Cystinosis
 - Histiocytosis X
- Congenital
 - Late-onset congenital, large ectopic gland
- Genetic syndromes
 - Down syndrome
 - Turner syndrome
- Secondary or tertiary hypothyroidism
 - Hypothalamic or pituitary disease

- Consumptive hypothyroidism
 - Due to increased type 3 iodothyronine deiodinase activity in hemangiomas

TREATMENT

MEDICATION

L-Thyroxine (synthetic thyroid hormone) replacement

- Indicated for the treatment of overt or compensated hypothyroidism
- 2–5 mcg/kg PO once daily
- Monitor T₄ and TSH and titrate dose to maintain normalized thyroid function tests.
- Duration of therapy:
 - Lifetime
 - In 30% of the cases, children with chronic lymphocytic thyroiditis will undergo spontaneous remission.
 - Need for treatment can be reassessed after growth is completed.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Whenever starting medication or adjusting dose, check T₄ and TSH at 4–6-week intervals to assess adequacy of the new dose.
- Once dose established, 6-monthly monitoring until linear growth completed
- Monitor response to treatment by measuring T₄ and TSH levels to ensure compliance.

PATIENT EDUCATION

Pharmacies in recent years have been recommending that L-thyroxine be administered on an empty stomach. The Drugs and Therapeutics Committee of the Pediatric Endocrine Society recommended that consistency in administration, coupled with regular dose titration based on

thyroid function laboratory tests, is more important than improving absorption by restricting intake to only times of empty stomach.

PROGNOSIS

- If patients are adherent, prognosis is excellent.
- Treated patients often resume growth at a rate greater than normal (catch-up growth).
- In children in whom treatment has been delayed, catch-up growth may not fully normalize height to predicted values.
- Other signs and symptoms resolve at a variable rate.
- Goiters in chronic lymphocytic thyroiditis may not completely regress with treatment (enlargement due to persistent inflammation does not correct, although TSH-mediated hypertrophy will).

COMPLICATIONS

- Most significant complication is impaired linear growth.
- Puberty can also be affected.
- Myxedema coma may occur.
- Encephalopathy of varied clinical presentation has been associated with high titers of thyroid antibodies, especially antimicrosomal; this condition responds well to corticosteroid treatment.

CODES

ICD10

- E03.9 Hypothyroidism, unspecified
- E03.8 Other specified hypothyroidism
- E06.3 Autoimmune thyroiditis

FAQ

- Q: What happens if my child forgets a dose?
- A: Give the dose as soon as you remember. If it is the next day, give 2

doses.

- Q: How long will my child have to take these pills?
- A: Probably for life.
- Q: Are there any side effects from the medication?
- A: No. The medication contains only the hormone that your child's thyroid gland is not making. The hormone is made synthetically, so there is also no infectious risk.
- Q: If my child takes twice the dose, will his or her growth catch up faster?
- A: Your child may grow a little faster but will also have adverse effects from having too much thyroid hormone.
- Q: Does the medication have to be taken at any particular time of day?
- A: No, but consistently choosing the same time of day helps to remember to take it. Do not take simultaneously with soy products, iron-containing medication, calcium supplements, or raloxifene (an antiestrogen medication) because they can cause malabsorption of levothyroxine.
- Q: What if my child needs surgery?
- A: Treatment of hypothyroidism such that the patient is euthyroid (normal thyroid status) prior to surgery is preferable whenever possible (only exception is ischemic heart disease requiring surgery). Euthyroid sick syndrome, which is common in very ill patients, should not be treated.

ACUTE DRUG WITHDRAWAL

Robert J. Hoffman

BASICS

DESCRIPTION

- Drug withdrawal is a physiologic response to an effectively lowered drug concentration in a patient with tolerance to that drug.
- Withdrawal results in a predictable pattern of symptoms that are reversible if the drug in question or another appropriate substitute is reintroduced.
- Sedative-hypnotic withdrawal is the most common life-threatening withdrawal syndrome in children. This includes withdrawal from barbiturates, benzodiazepines, as well as gamma-hydroxybutyrate and similar substances.
- Other substances that are associated with withdrawal syndromes include opioids, selective serotonin reuptake inhibitors (SSRIs), and caffeine.

EPIDEMIOLOGY

- The most common life-threatening withdrawal syndrome, alcohol withdrawal, rarely occurs in children.
- Neonates born to alcohol-dependent mothers are at risk.

RISK FACTORS

Patients receiving sedatives or analgesics capable of causing tolerance are at risk. This is particularly true with infusions or high doses of such substances in previously naïve patients.

GENERAL PREVENTION

- Clinician familiarity with tolerance and withdrawal associated with prescribed medications allows appropriate drug tapering.
- Drug abuse prevention is appropriate for all children.

PATHOPHYSIOLOGY

- Altered CNS neurochemistry is the most important and clinically

relevant aspect of withdrawal pathophysiology.

- Under normal conditions, the CNS maintains a balance between excitation and inhibition. Although there are several ways to achieve this balance, excitation is constant and actions occur through removal of inhibitory tone.
- Relative to adults and younger children, adolescents are more prone to develop dependence and withdrawal syndrome due to immaturity of their prefrontal cortex.

ETIOLOGY

- Neonates
 - Maternal alcohol, caffeine, opioid, sedative-hypnotic, or SSRI use may result in a neonatal abstinence syndrome.
 - Treatment with caffeine, opioids, or sedative-hypnotics may result in subsequent development of an abstinence syndrome.
- Older children
 - Subsequent to treatment with opioids, or sedative-hypnotics, an abstinence syndrome may result.
 - Substance abuse, particularly opioids, gamma-hydroxybutyrate, or other sedative-hypnotics, may result in an abstinence syndrome.
 - Frequent caffeine or nicotine use may lead to an abstinence syndrome.
- Use of opioid antagonists such as naloxone, naltrexone, and nalmeferone is associated with opioid withdrawal.

DIAGNOSIS

- Drug withdrawal is a clinical diagnosis.
- Patients should be evaluated for associated diagnoses such as traumatic injury, pneumonia, etc.

HISTORY

- Typically, a history of substance exposure, either direct exposure or maternal use, will be elicited.
 - Exposure may be to prescribed medication or abusable substances.
 - Substance use by the mother or child might intentionally be

concealed.

- The timing of withdrawal varies depending on the half-life of the substance involved.
 - The shorter the half-life, the sooner the onset of withdrawal and typically the more severe withdrawal symptoms.
- Alcohol or sedative-hypnotics
 - Withdrawal from these may result in tremulousness, diaphoresis, agitation, insomnia, altered mental status, or withdrawal seizures.
 - Baclofen withdrawal is more frequently severe or life threatening relative to benzodiazepine withdrawal. History of pump manipulation or malfunction should be sought.
- Caffeine
 - Withdrawal may result in dysphoria, headache, behavioral changes, or agitation.
- Opioids
 - Nausea, vomiting, diarrhea, irritability, yawning, sleeplessness, diaphoresis, lacrimation, tremor, and hypertonicity may result.
 - Neonates can also have seizures, a high-pitched cry, skin mottling, and excoriation. These latter signs and symptoms are more typical of opioid withdrawal and rarely occur with neonatal alcohol withdrawal.
- Nicotine
 - Dysphoria, agitation, behavioral changes, and increased appetite may all occur.
- SSRIs
 - Neonatal withdrawal from SSRIs may result in jitteriness, agitation, crying, shivering, increased muscle tone, breathing and sucking problems, as well as seizure.
 - Children withdrawing from SSRIs may have jitteriness, agitation, dysphoria, behavioral changes, shivering, increased muscle tone, and seizure.

PHYSICAL EXAM

- Vital signs including temperature should be evaluated regularly. Vital sign changes such as tachycardia and hypertension may occur concomitantly with acute drug withdrawal.

- Technology-dependent patients, such as children with an intrathecal baclofen pump, should have evaluation of the machine to determine if it is working properly.
- Most cases of substance withdrawal only result in behavioral changes.
- Opioid withdrawal may be accompanied by diaphoresis, mydriasis, yawning, and lacrimation.
- Sedative-hypnotic withdrawal may result in hypertension, tachycardia, hyperthermia, agitation, hallucinations, and seizure.

DIAGNOSTIC TESTS & INTERPRETATION

Imaging

Neuroimaging to rule out intracranial pathology may rarely be indicated.

Diagnostic Procedures/Other

- No routine lab tests are indicated for patients with substance withdrawal.
- Tests necessary to rule out differential diagnoses should be obtained when appropriate.

DIFFERENTIAL DIAGNOSIS

- Hypoglycemia
- Intoxication with sympathomimetics, anticholinergics, theophylline, caffeine, aspirin, or lithium
- Thyroid storm
- Serotonin syndrome
- Neuroleptic malignant syndrome
- Encephalitis
- Meningitis
- Sepsis

TREATMENT

MEDICATION

- Symptom-triggered treatment has been demonstrated to be superior to fixed-regimen treatment in terms of patient outcome as well as length of stay.

- Patients experiencing withdrawal from benzodiazepines or barbiturates after treatment in a chronic or intensive care setting may be treated by reinstituting the drug and then tapering.
- Iatrogenic withdrawal induced by use of opioid antagonists should not be treated by opioid administration.
 - Withdrawal induced by naloxone should abate rapidly due to the brief half-life of naloxone.
 - Withdrawal induced by naltrexone or nalmefene will be much longer lasting. Symptomatic treatment may be indicated.
- There is no fixed quantity of drug to use for any withdrawal syndrome. Each patient requires a unique quantity of drug.
 - Repeated dosing should continue until the symptoms are controlled, at which point maintenance and then tapering can occur.
- Sedative-hypnotic withdrawal
 - Ideally, withdrawal is treated with the same class of substance, such as benzodiazepine or barbiturate, if not the precise same drug.
 - Benzodiazepines are particularly useful due to the rapid onset of effect.
 - Diazepam has active metabolites that assist in tapering the drug.
 - Propofol is an outstanding medication for treatment of severe alcohol or sedative-hypnotic withdrawal in adults.
 - Propofol may be used in pediatric cases refractory to benzodiazepines and barbiturates.
 - Use is associated with respiratory depression.
 - Clinicians must be capable of airway management and expect airway support to be necessary when propofol is used.
 - Propofol use is safe in children, but rare cases of metabolic acidemia have occurred when prolonged infusions are used. Prolonged use of propofol infusion should be accompanied by close observation for acidemia.
- Opioid withdrawal
 - Heroin (as well as other opioids) withdrawal is best treated with an opioid of similar potency and equal or longer duration of action.
 - Methadone is a preferred treatment for withdrawal in adolescents and adults, but most neonatologists have limited or no experience

with this drug.

- Patients who experience opioid withdrawal in the setting of chronic or intensive care may be treated by reinstituting infusion or dosing of the drug they were on before withdrawal symptoms and then tapering this, typically by 10% daily.
- Caffeine withdrawal
 - Caffeine as soft drink or tea taken to treat headache or agitation
 - Neonatal caffeine abstinence symptoms may be treated by reinstituting 75–100% of the caffeine dosage that was discontinued. This amount is then tapered, typically by 10% daily.
- Nicotine withdrawal is not typically treated in children.
- Use of nicotine patch, gum, or other delivery methods is used to increase success rate of abstinence rather than for medical management of the withdrawal syndrome.

ADDITIONAL TREATMENT

General Measures

- Initial stabilization
 - Initial management is aimed at evaluating and supporting airway, breathing, circulation, serum glucose, and ECG (“A, B, C, D, E”).
- Supportive care is the most important general principle.
- The illness is managed with intent of close monitoring and addressing issues as they arise.

ISSUES FOR REFERRAL

- Any patient with substance abuse issues should be referred for appropriate psychiatric or drug counseling.
- Most cases of substance withdrawal are best handled by an addiction specialist, medical toxicologist, intensivist, or other clinician experienced with management of withdrawal.

INPATIENT CONSIDERATIONS

Admission Criteria

- Inpatient treatment for alcohol or sedative-hypnotic withdrawal is mandatory.
- Although withdrawal from opioids and SSRIs is not life threatening, admission with initial management as an inpatient is preferable.

IV Fluids

- Maintenance IV fluid may be required in patients who are unable to take PO.
- Dehydration was once a leading cause of death among patients with alcohol withdrawal.

Discharge Criteria

- Inpatients who have been converted from parenteral to oral medications and are controlled with oral medications may be discharged for home tapering.
- Patients who never require parenteral therapy may be discharged with oral replacement medication after consultation with the appropriate specialist.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- If disposition will be discharge, it is crucial to ensure that the patient's condition is stable before discharge.
- If there is any question regarding whether the patient can be appropriately managed as an outpatient, initial inpatient management is preferable.

Patient Monitoring

- Sedative-hypnotic withdrawal or any other withdrawal syndrome with severe symptoms is best cared for with initial cardiopulmonary monitoring until vital sign abnormalities are controlled with appropriate replacement therapy.
- Patients should be closely monitored until vital signs are within acceptable limits.
- Vigilance for agitation or delirium with sedative-hypnotic withdrawal is necessary.
- Vigilance to detect oversedation and respiratory depression is necessary.

PATIENT EDUCATION

Patients or parents should be aware of withdrawal symptoms to be vigilant

for detecting future events.

PROGNOSIS

- With appropriate therapy, withdrawal is well tolerated.
- Poor prognostic factors are primarily related to comorbidities.

COMPLICATIONS

Complications of hypertension, tachycardia, hyperthermia, and CNS agitation or seizure may occur with sedative-hypnotic withdrawal.

ACUTE KIDNEY INJURY

Shina Menon • Stuart Goldstein

BASICS

DESCRIPTION

- Acute kidney injury (AKI) is defined as an abrupt (within 48 hours) reduction in kidney function with an absolute increase in serum creatinine of more than or equal to 0.3 mg/dL, or a 1.5-fold increase from baseline or a reduction in urine output (documented oliguria of less than 0.5 mL/kg per hour for more than 6 hours).
- The pediatric modified RIFLE (risk, injury, failure, loss, and end-stage renal disease) system classifies the degree of renal insult by changes in serum creatinine and/or the duration of oliguria.
- In AKI, the urine output is variable: anuria, oliguria and, in some cases, polyuria can all be observed at presentation.

EPIDEMIOLOGY

- The epidemiology of AKI has changed over the recent years from primary kidney disease to a syndrome secondary to other systemic illness.
- AKI may be seen in up to 10% of all hospitalized children. The incidence is higher in ICU admissions and with increasing multiorgan disease severity.

PATHOPHYSIOLOGY

The pathogenesis of AKI is multifactorial. It may be initiated by ischemia or toxins, and the subsequent injury involves a complex interplay between vasoconstriction, leukostasis, vascular congestion, cell death, and abnormal immune modulators.

ETIOLOGY

Previously, AKI was subcategorized into 3 groups: prerenal, renal, and postrenal. The differentiation between “prerenal” and “renal” causes can be difficult because renal hypoperfusion may coexist with any stage of

AKI.

- Prerenal azotemia (functional)
 - Decreased glomerular filtration rate (GFR) resulting from renal hypoperfusion in a structurally intact kidney
 - Often rapidly reversible when the underlying cause is corrected
- Intrinsic (structural)
 - Disorders that directly affect the kidney
 - Acute tubular necrosis (ATN) was used in the past to describe a form of intrinsic AKI from severe and persistent hypoperfusion of the kidneys. However, the histologic diagnosis of tubular necrosis is rarely confirmed by biopsy.
 - Glomerular disorders include the various forms of acute glomerulonephritis (AGN) (e.g., postinfectious, rapidly progressive [crescentic]).
 - Vascular lesions compromise glomerular blood flow. Hemolytic uremic syndrome (HUS) is the most common vascular disorder that causes intrinsic AKI in children.
 - Acute interstitial nephritis (AIN) most often occurs as a result of exposure to medications such as NSAIDs. It may also be associated with infections (e.g., pyelonephritis), systemic diseases, or tumor infiltrates.
- Postrenal
 - Obstructive process (either structural or functional)
 - Obstruction can be in the lower tract or bilaterally in the upper tracts (unless the patient has a single kidney).
 - More common in newborns

DIAGNOSIS

HISTORY

- Previous infection, neurogenic bladder, single kidney
- Exposure to nonsteroidal anti-inflammatory agents, β -lactam antibiotics, acyclovir, aminoglycosides, amphotericin B, cisplatin
- Gross hematuria: AGN (tea colored), renal calculi (bright red blood)
- Trauma: crush injury

- Signs and symptoms: fever, rash bloody diarrhea, pallor, severe vomiting or diarrhea, abdominal pain hemorrhage, shock, anuria, polyuria

PHYSICAL EXAM

- General: weight and hydration status; shock, edema (calculation of percent fluid overload), jaundice
- Lungs: rales
- Heart: gallop
- Abdomen/pelvis: mass
- Skin: rash, petechiae
- Joints: arthritis

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- All patients with AKI should have a urinalysis with microscopic exam, serum chemistries, and a CBC:
 - Urinalysis: specific gravity (>1.020 suggests prerenal AKI), proteinuria (>3+ intrinsic, glomerular AKI), eosinophiluria (AIN), pyuria (pyelonephritis), granular casts (prerenal, ATN), pigmenturia (ATN), erythrocyte casts (glomerulonephritis, AIN, ATN)
 - Serum chemistries: hyponatremia, acidosis, hyperkalemia, hypocalcemia, hyperphosphatemia
 - CBC: microangiopathic hemolytic anemia, thrombocytopenia (i.e., HUS), eosinophilia (i.e., AIN)
 - Selected patients require further studies, including serologies, urine electrolytes, imaging, and renal biopsy:
 - Serologies: hypocomplementemia, antineutrophil cytoplasmic antibodies, antinuclear antibodies (AGN)
- The fractional excretion of sodium (FENa)
 - Can be useful to assess tubular function. $FENa = [(UNa/PNa)/(Ucreat/Pcreat)] \times 100$.
 - The FENa should not be obtained after diuretics are administered. FENa >2: ATN; FENa <1: AGN, prerenal
 - FENa can be <1% despite ATN in case of radiocontrast nephropathy or pigment nephropathy.

- Fractional excretion of urea (FEUrea)
 - Less affected by diuretics
 - $FEUrea = [(U_{urea}/P_{urea})/(U_{creat}/P_{creat})] \times 100$
 - FEUrea <35: prerenal AKI; FEUrea >50: ATN

Imaging

- Chest radiograph: cardiomegaly or pulmonary edema (fluid overload)
- Renal US: hydronephrosis, trabeculated bladder (i.e., obstruction), increased echogenicity (i.e., ATN, AIN, AGN, HUS), abnormal Doppler study (renal venous thrombosis)

Diagnostic Procedures/Other

Renal biopsy: indicated in patients with prolonged, unexplained AKI or suspicion for crescentic glomerulonephritis

DIFFERENTIAL DIAGNOSIS

- Chronic kidney disease: insidious, associated with poor growth, normocytic anemia, hyperparathyroidism
- Azotemia (elevated BUN): hypercatabolic states including corticosteroid therapy or upper GI bleeding
- Elevated creatinine: caused by rhabdomyolysis, drugs (trimethoprim-sulfamethoxazole, cimetidine)

TREATMENT

MEDICATION

- Clearance of many medications is impaired in AKI. Careful monitoring of drug dosing and levels can minimize toxicity.
- Low-dose (renal dose) dopamine is ineffective in improving kidney function in AKI. Loop diuretics (furosemide) and osmotic diuretics (mannitol) do not affect the progression or outcome of AKI and may be harmful.
- Bicarbonate may be useful to treat AKI in rhabdomyolysis.
- N-acetylcysteine and bicarbonate, used prophylactically, may prevent contrast nephropathy.

ADDITIONAL THERAPIES

- Supportive
 - Avoid nephrotoxic medications when possible.
 - Monitor electrolytes closely. Avoid drugs, fluids, or foods containing potassium in patients with oliguria or anuria.
 - Hyponatremia is usually due to free water excess and should be managed with fluid restriction. Hypertonic saline should be used only if CNS symptoms are present.
- Fluid management
 - Can be divided into 3 phases based on the clinical status
 - Fluid resuscitation/repletion: The goal is to restore end-organ perfusion.
 - Fluid balance maintenance: After initial resuscitation, the patient's ongoing fluid needs (blood products, medications, nutrition) should be balanced with the output (urine and insensible losses). Fluid restriction may be needed to avoid worsening fluid overload. Increasing degrees of fluid overload (%FO) at initiation of renal replacement therapy (RRT) are independently associated with mortality.
 - Fluid overload may be calculated as:
 - $\%FO = (\text{Fluid Input [L]} - \text{Fluid Output [L]}) / \text{Patient ICU admission weight (kg)} \times 100$
 - Fluid removal/recovery: If the fluid conservative strategy does not work, RRT may be needed to remove the volumes associated with patient needs.
- RRT is indicated for fluid overload, refractory acidosis, severe hyperkalemia, and uremic symptoms (e.g., pericarditis, lethargy, bleeding diathesis). The modality of RRT (hemodialysis or continuous RRT) depends on the hemodynamic status of the patient.
- Provision of adequate nutrition is essential due to the high prevalence of malnutrition in this group and the associated morbidity and mortality. Protein restriction with the aim of delaying RRT is not recommended.
- Specific treatment based on etiology: Each cause of AKI may necessitate specific treatment, such as fluid resuscitation (i.e., prerenal), urologic intervention (i.e., obstruction), and corticosteroids

(i.e., AIN, some forms of AGN).

INPATIENT CONSIDERATIONS

Initial Stabilization

- If hypovolemic, rapidly establish euvoemia with 0.9% NS or balanced solution boluses.
- If urine output remains low after euvoemia is established, begin fluid restriction (insensible losses and urine output).
- In severe hyperkalemia (>6.5 mEq/L), consider the following:
 - Calcium gluconate (100 mg Ca gluconate salt/kg IV) over 5–10 minutes if symptomatic
 - Glucose (0.5 g/kg) and insulin (0.1 U/kg) IV over 30 minutes
 - Sodium bicarbonate (1–2 mEq/kg) IV over 10–30 minutes if acidotic
 - When administering sodium bicarbonate, monitor serum calcium carefully because the hypocalcemia may worsen.
 - Kayexalate (1 g/kg) PO or PR in sorbitol
 - Furosemide (1–2 mg/kg) if renal function is adequate
 - RRT

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- The likelihood of recovery from AKI depends on the underlying cause.
- AKI may result in full recovery or incomplete recovery leading to chronic kidney disease. In severe cases, nonrecovery may lead to end-stage renal disease.
- Long-term follow-up to monitor renal function is recommended.

PROGNOSIS

The mortality rate increases in patients with multisystem organ failure despite good supportive care. AKI is independently associated with increased mortality in ICU patients.

COMPLICATIONS

- A significant postobstructive diuresis can be seen after treatment for

obstructive AKI.

- Fluid overload, resulting in congestive heart failure, hypertension, or hyponatremia
- Hyperkalemia, affecting cardiac function by causing arrhythmias
- Uremia, manifest by mental status changes, increased risk of bleeding, and infection
- Metabolic acidosis
- Hypocalcemia, causing tetany

CODES

ICD10

- N17.9 Acute kidney failure, unspecified
- N17.0 Acute kidney failure with tubular necrosis
- N00.9 Acute nephritic syndrome with unsp morphologic changes

FAQ

- Q: What is the expected recovery time in patients with AKI who present with anuria?
- A: Recovery time depends on the etiology of the AKI. Children with HUS may recover in days to weeks. In severe HUS or AKI requiring RRT, ongoing recovery to new, baseline renal function occurs over several months. Those with ATN recover days after treatment for the

cause. Children with AKI secondary to an obstructive process usually recover as soon as the obstruction is removed.

- Q: When should renal function return to normal?
- A: Renal function may never return to normal in patients with long-standing anuria. In other cases, after recovery occurs, serum creatinine levels return to normal within weeks.
- Q: Which indices should be observed after a patient recovers from AKI?
- A: Patients recovering from AKI should have renal function (serum creatinine and cystatin C), BP, and urinalysis for proteinuria monitored regularly.

ACUTE LIVER FAILURE

Krupa R. Mysore • Kristin L. Van Buren • Eric H. Chiou

BASICS

DESCRIPTION

- A set of criteria has been proposed to diagnose pediatric acute liver failure (ALF).
 - Biochemical evidence of liver injury due to rapid loss of hepatocyte function
 - No previous history of chronic liver disease
 - Coagulopathy not responsive to vitamin K administration
 - International normalized ratio (INR) >1.5 in presence of encephalopathy or INR >2 without encephalopathy
- In older children, in whom hepatic encephalopathy can be more easily assessed, ALF may more simply be defined as follows:
 - Onset of encephalopathy <8 weeks after the onset of symptoms referable to liver dysfunction in a patient without preexisting liver disease

EPIDEMIOLOGY

- Exact frequency of ALF in children is unknown but accounts for 10–15% of pediatric liver transplants in the United States annually.
- In infants and children <3 years of age, indeterminate and metabolic etiologies predominate.
- In older children, drug-induced toxicity (especially acetaminophen), autoimmune hepatitis become more common.
- Infectious etiologies, (e.g., viral hepatitis) vary in prevalence based on geographic region.

PATHOPHYSIOLOGY

- Hepatocellular necrosis leads to release of growth factors that promote hepatic regeneration.
- Hepatic failure may become irreversible if:
 - The initial insult overcomes the liver's regenerative capacity.

- The offending agent or derangement is not eliminated or corrected.
- Secondary complications, such as shock or disseminated intravascular coagulation, lead to further injury.

ETIOLOGY

The major causes of ALF can be grouped into the following broad categories:

- Indeterminate
- Drug-induced/toxin
- Metabolic/genetic
- Infectious
- Vascular/ischemic
- Malignancy
- Immune dysregulation

DIAGNOSIS

HISTORY

- Age: may suggest possible etiologic subgroup
- Toxin exposure: prescription, over-the-counter, herbal, or supplemental medications
- Symptoms of viral prodrome
- Travel history, exposure history
- Length of symptoms, acuity of onset
- Associated symptoms/ROS:
 - Jaundice, bleeding, bruising
 - Weakness, fatigue
 - Abdominal distension, pain, diarrhea
 - Pruritus secondary to cholestasis

PHYSICAL EXAM

- Skin: jaundice, bruising
- Eyes: scleral icterus
- Abdomen: hepatomegaly, ascites with dullness to percussion or fluid wave, splenomegaly
- Neurologic

- Sequential mental status exams are paramount to monitor for change and should include age-appropriate questions.
- Assess for presence of encephalopathy:
 - Grade I: confused, altered sleep; reflexes normal, may have tremor or apraxia
 - Grade II: drowsy, inappropriate behavior; hyperreflexic or asterixis; dysarthria or ataxia
 - Grade III: stupor but may obey simple commands, sleepy; hyperreflexic, asterixis, Babinski-positive; increased general tone
 - Grade IV: comatose; reflexes absent; decerebrate or decorticate posturing

DIAGNOSTIC TESTS & INTERPRETATION

Imaging

- Abdominal ultrasound with Doppler: visualization of both hepatic parenchyma and vasculature (direction of portal flow, presence of thrombosis)
- Head CT scan without IV contrast in presence of encephalopathy or neurologic signs to rule out intracranial hemorrhage or cerebral edema

Diagnostic Procedures/Other

- Initial laboratory testing
 - Hepatocellular injury: aminotransferases (AST, ALT) often markedly elevated; degree of elevation may depend on mechanism and time frame of injury.
 - Biliary injury/obstruction: elevated alkaline phosphatase, γ -glutamyl transpeptidase (GGT), total/conjugated bilirubin
 - General labs: CBC with differential, electrolytes, glucose, blood urea nitrogen and creatinine, amylase/lipase
- Assessment of synthetic function
 - Prolonged PT/INR (with adequate supply of vitamin K)
 - Depressed factors V, VII levels
 - Hypoalbuminemia
 - Hypoglycemia: Frequent glucose measurements should be followed during initial evaluation and with any mental status or neurologic change.

- Encephalopathy: ammonia level (has not been proven to correlate directly to presence or grade of encephalopathy)
- Tests to determine etiology
 - Testing priority should be guided by the age group and population, and for conditions amenable to specific therapies.
 - Toxin: urine or serum drug screen, serum acetaminophen and aspirin levels
 - Infectious: hepatitis virus serologic testing, comprehensive viral cultures; PCR testing for EBV, CMV, HSV, and other viruses; antibody tests
 - Autoimmune hepatitis: antinuclear, anti-smooth muscle/F-actin, anti-LKM antibodies, total IgG
 - Wilson disease: decreased serum ceruloplasmin (may not be reliable in setting of ALF), increased serum or urinary copper, Coombs-negative hemolytic anemia
 - Pregnancy test in adolescent females
 - Metabolic: urine succinylacetone, reducing substances, and organic acids; plasma amino acids, acylcarnitine profile, lactate/pyruvate, creatinine kinase; newborn screen
 - Hemophagocytic lymphohistiocytosis: ≥ 2 cytopenias, elevated ferritin, elevated triglycerides, and low fibrinogen
 - Gestational alloimmune liver disease (neonatal hemochromatosis): severe hypoglycemia and coagulopathy, elevated ferritin with near-normal aminotransferase. Evidence of iron deposition on buccal biopsy or abdominal MRI
- Liver biopsy: Generally, not considered critical for management or diagnosis due to substantial risks of hemorrhage. Transjugular approach may reduce risks. May be appropriate to attempt to identify a specific etiology that may influence treatment strategy (e.g., Wilson disease). Severity of necrosis may not predict potential liver recovery.

DIFFERENTIAL DIAGNOSIS

The cause of ALF can be indeterminate in up to 50% of cases across all age groups. Etiologic subgroups include the following:

- Drug-induced/toxin
 - Acetaminophen: most common in older children and adolescents

- Salicylates, iron compounds, anticonvulsants, antibiotics
- Recreational drugs
- Amanita species (mushrooms)
- Metabolic/genetic/misc: early infancy
 - Galactosemia, tyrosinemia
 - Gestational alloimmune liver disease
 - Storage diseases
 - Mitochondrial disorders
 - Fatty acid oxidation disorders
 - Hereditary fructose intolerance
- Metabolic/genetic/misc: older children
 - Autoimmune hepatitis
 - Wilson disease
 - Pregnancy (HELLP syndrome, AFL)
 - Reye syndrome
- Infectious
 - Hepatitis virus: A, B, E; less commonly C
 - Herpes virus: HSV, EBV, CMV, VZV, HHV6
 - Echovirus, especially in neonates
 - Parvovirus, adenovirus
- Vascular/ischemic
 - Congestive heart failure
 - Hypotensive shock
 - Budd-Chiari syndrome: hepatic venous outflow obstruction
 - Veno-occlusive disease: Nonthrombotic occlusion of hepatic venules, typically occurs following stem cell transplantation.
- Malignancy
 - Primary: hepatoblastoma, hepatocellular carcinoma
 - Other: leukemia, lymphoma, hemophagocytic lymphohistiocytosis
- Heatstroke, hyperthermia, rhabdomyolysis

TREATMENT

MEDICATION

- Hematologic

- Vitamin K: Administer IV or SQ/IM for prolonged PT/INR, and monitor response with repeat PT/INR 4–6 hours afterward.
- FFP and cryoprecipitate should be reserved for acute severe bleeding or prior to invasive procedure; their use prohibits subsequent monitoring of PT/INR or specific factor levels.
- Recombinant factor VIIa can be used in cases of acute severe bleeding.
- Neurologic/hepatic encephalopathy
 - Sedatives, especially benzodiazepines, should be avoided, as they may worsen encephalopathy.
 - Lactulose (oral, enema forms) should be used if encephalopathy present; goal is to acidify stool (pH <6) and increase frequency of stool but not cause diarrhea.
 - Oral or rectal administration of antibiotics (neomycin, rifaximin) may be effective by reducing ammonia production in the gut.
 - Elevated arterial ammonia levels may help predict development of encephalopathy and intracranial hypertension.
- Infectious disease
 - Prophylactic antibiotics and antifungal medications if febrile, after obtaining cultures from any central venous access or catheterization.
- Renal
 - Nephrotoxic drugs should be avoided when possible. Diuretics should be used with caution; renal dose medications if renal compromise present
 - Renal replacement therapy as indicated
- Other:
 - N-acetylcysteine is the treatment for acetaminophen-induced hepatic toxicity.
 - IV acid suppression should be considered.
 - Removal of offending agent when identified

ADDITIONAL TREATMENT

General Measures

- Close monitoring, preferably in an ICU setting with a liver transplant program
- General supportive care

- Fluid restriction: 75–95% of maintenance requirements to prevent worsening of portal hypertension, ascites, and pulmonary edema
- Sodium restriction: Patients should typically not receive >0.25 NS as maintenance fluids. A total sodium intake of 1 mEq/kg/24 h is usually adequate. Hyponatremia should not be corrected with hypertonic saline, as this can worsen fluid overload and encephalopathy.
- Glucose infusion: Maintenance fluid typically should include 10% dextrose; glucose infusion may need to be increased, as patients are at risk for hypoglycemia.
- Nutrition: Adequate nutrition should be maintained either via enteral route or TPN.
- Blood products should be given slowly to avoid rapid expansion of intravascular space.
- Minimize invasive catheterization when possible due to infection risk.

SURGERY/OTHER PROCEDURES

- Those more likely to require liver transplantation include children with ALF secondary to indeterminate cause, idiosyncratic drug toxicity, hepatic vein thrombosis, or Wilson disease.
- Transplant-free survival >50% for ALF due to acetaminophen, hepatitis A, shock liver or pregnancy-related disease, whereas all other etiologies have <25% transplant free survival.
- Currently, available liver support systems are not recommended outside of clinical trials.

INPATIENT CONSIDERATIONS

Initial Stabilization

- Initial evaluation should include assessment of neurologic status.
- Elective intubation as well as ICP monitoring should be considered in grade III or IV encephalopathy with somnolence.
- Aggressive initial fluid resuscitation should be avoided unless there is evidence of hemodynamic compromise.
- Central venous access should be considered to allow for higher glucose infusion rates and for central nutrition.

ONGOING CARE

PROGNOSIS

- Etiology of ALF provides good indicator of prognosis and also dictates management.
- Existing liver failure scoring systems based on biochemical markers (e.g., INR) and/or clinical features, including the Kings College Hospital Criteria, have not been shown to be useful for predicting survival or death in pediatric ALF.
- Decisions for liver transplantation in pediatric ALF often challenging due to uncertainty of diagnosis and possibility of spontaneous recovery, potential morbidity/mortality of the transplant procedure itself, and the limited number of organs available.
- Overall 1-year survival following liver transplant is lower in patients transplanted for ALF compared to chronic liver failure; however, after the 1st year this trend is reversed and ALF patients have better long-term survival.

COMPLICATIONS

- Complications are a direct consequence of loss of hepatic metabolic function:
 - Hepatic encephalopathy: decreased elimination of neurotoxins or depressants
 - Cerebral edema: pathogenesis incompletely understood
 - Coagulopathy: failure of hepatic synthesis of clotting and fibrinolytic factors
 - Hypoglycemia: impaired glucose synthesis and release, decreased degradation of insulin
 - Acidosis: failure to eliminate lactic acid or free fatty acids
 - Hepatorenal syndrome: typically low urine sodium and no improvement with volume expansion; continuous venovenous hemofiltration or dialysis may be necessary.
- In cases of suspected hepatic encephalopathy, consider other etiologies of neurologic change including hypoglycemia, intracranial hemorrhage, acute infection, or sepsis.

- There is often rapid progression through the stages of encephalopathy. Increased intracranial pressure can develop quickly and can lead to irreversible neurologic sequelae.

CODES

ICD10

- K72.00 Acute and subacute hepatic failure without coma
- K71.10 Toxic liver disease with hepatic necrosis, without coma

FAQ

- Q: What are the most common causes of ALF in infants?
- A: Up to 40–50% of cases are indeterminate, followed by neonatal

hemochromatosis, viral infection, and metabolic disorders.

- Q: What is the risk of bleeding in ALF-associated coagulopathy?
- A: Spontaneous, clinically significant bleeding in ALF is generally rare, despite abnormal INR. Thromboelastography (TEG), which assesses overall hemostasis including the cumulative effects of procoagulant and anticoagulant proteins, fibrinogen, platelets, and red blood cells, may be a better guide for administration of blood products in ALF than INR.
- Q: Is the initial level of elevation of transaminases is directly correlated to the prognosis of patient?
- A: False. In viral hepatitis and acetaminophen toxicity, initial transaminases can be in 1,000s, but patients can have complete recovery.

ACUTE LYMPHOBLASTIC LEUKEMIA

Latika Puri • Caroline Hastings

BASICS

DESCRIPTION

- Acute lymphoblastic leukemia (ALL) is a hematopoietic malignancy that results from malignant proliferation of immature WBC (B cells and T cells).
- Risk group classification:
 - Infant ALL: age less than 1 year
 - Standard risk ALL: age 1 to younger than 10 years; initial WBC count $<50,000/\mu\text{L}$
 - High risk ALL: age 10 years or older; WBC $\geq 50,000/\mu\text{L}$
- Further risk stratification done based on multiple factors including National Cancer Institute (NCI) criteria (age and WBC count), biologic, cytogenetic characteristics, and response to initial therapy. This classification determines the intensity of therapy and prognosis.
 - Low-risk ALL: NCI standard risk group
 - Favorable cytogenetic changes (hyperdiploidy, trisomies of 4, 10, and 17; t[12;21]);
 - Pre B lymphoblasts and negative minimal residual disease (MRD) at end of induction
 - Average risk ALL: NCI standard risk group
 - Noncontributory cytogenetics
 - Negative MRD at end of induction
 - No extramedullary (CNS or testicular) involvement
 - Negative MRD at end of induction
 - High-risk ALL: NCI high-risk group
 - Age >10 years regardless of WBC count, extramedullary (CNS or testicular) involvement
 - T-cell phenotype
 - No or very low MRD at end of induction
 - Very high-risk ALL

- Unfavorable cytogenetics (t[9;22] Philadelphia positive ALL)
- Hypodiploidy
- MLL gene rearrangement
- Induction failure (>25% lymphoblasts in bone marrow at end of induction)
- Positive MRD at the end of induction

EPIDEMIOLOGY

- ALL is the most common childhood malignancy.
- Accounts for approximately 30% of cancer diagnosis in children younger than 15 years of age
- More common in Caucasians and males
- ALL incidence: 3–4 cases per 100,000 per year
- Peak incidence is between ages 2 and 5 years.

RISK FACTORS

- Prior cancer therapy (chemotherapy or radiation)
- Twin with ALL
- Genetic syndrome listed in the following sections

Genetics

- Increased risk of leukemia, higher with monozygotic twin
- Associated genetic syndromes
 - Trisomy 21 (Down syndrome)
 - Fanconi anemia
 - Bloom syndrome
 - Shwachman-Diamond syndrome
 - Ataxia telangiectasia
- Neurofibromatosis type 1
- Li-Fraumeni syndrome p53 (familial cancer syndrome)
- Congenital immunodeficiencies (Wiskott-Aldrich syndrome)

PATHOPHYSIOLOGY

Leukemia arises from lymphoid progenitor cells that have sustained multiple specific genetic damages that lead to malignant transformation and proliferation, lack of cell maturation, and resistance to normal cell death processes (apoptosis). This lymphoblastic proliferation replaces the

normal bone marrow precursor cells, causing ineffective hematopoiesis and infiltration of lymphatic tissue and end organs.

DIAGNOSIS

- Clinical features due to direct invasion of the bone marrow:
 - Pancytopenia: anemia, thrombocytopenia, leukopenia, or neutropenia
 - Anemia: irritability, fatigue, anorexia, headache, pallor
 - Thrombocytopenia: bleeding is usually mild and manifests as petechiae, bruising, gingival oozing, epistaxis
- Fever: may be a sign of presumed cytokine release or underlying infection due to neutropenia and immunosuppression
- Bone pain
 - Typically long bones
 - Could be due to direct leukemic infiltration of the periosteum or expansion of marrow cavity by leukemic cells
 - Pathologic fractures, leukemic lines on plain radiographs, or T2-weighted changes on MRI
- Testicular involvement (2–5 % of the boys), unilateral or bilateral painless testicular enlargement
- CNS involvement (2–5% of patients on presentation for B cell, 10–15% for T-cell ALL)
 - Increased intracranial pressure (morning headache, vomiting, lethargy, visual changes, seizures, CN VI palsy, diplopia, and esotropia)
- Superior vena cava (SVC) syndrome (due to a mediastinal mass)
 - Swelling of the face, neck, chest, and, rarely, upper arms with or without visible venous distension, cough, dyspnea, dysphagia
- Leukostasis (large number of deformable blasts plugging the microcirculation)
 - Respiratory symptoms: dyspnea, hypoxia
 - Neurologic symptoms: visual changes, headache, dizziness, tinnitus, lethargy
 - Rare symptoms including renal insufficiency, priapism, acute limb

ischemia

- Spinal cord compression (due to a chloroma, an extramedullary collection of lymphoblasts): extremity weakness, numbness, and tingling

PHYSICAL EXAM

- Pallor (anemia)
- Tachycardia/murmurs (anemia)
- Lymphadenopathy (leukemic infiltration)
- Hepatosplenomegaly (leukemic infiltration)
- Testicular enlargement (leukemic infiltration)
- Bone: tenderness, fracture (marrow infiltration)
- Skin: bruises, petechiae, rash in form of subcutaneous nodules (leukemia cutis, most commonly seen in infants)
- Papilledema (CNS involvement)
- Focal neurologic signs (CNS involvement, chloroma)

DIAGNOSTIC TESTS & INTERPRETATION

- CBC
 - Increased or decreased WBC (50% present with WBC $<10,000/\mu\text{L}$ and 20% present with WBC $\geq 50,000/\mu\text{L}$)
 - Anemia: Hgb <10 g/dL (80% of cases)
 - Thrombocytopenia (platelets $<100,000/\mu\text{L}$ in 75% at presentation)
 - Peripheral smear: may see circulating lymphoblasts, especially with high WBC
- Serum chemistry
 - Signs of tumor lysis: elevated uric acid, hyperkalemia, hyperphosphatemia (with secondary hypocalcemia), elevated lactate dehydrogenase (LDH)
 - Elevated liver enzymes (leukemic infiltrate)
 - Elevated creatinine (due to uric acid/calcium phosphate crystal deposition in renal tubules or leukemic infiltrates)

Imaging

- CXR: mediastinal mass (5–10% of cases)
- Plain films of long bones in case of bone pain/tenderness may show leukemic lines.

Diagnostic Procedures/Other

- Bone marrow aspirate and biopsy (presence of more than 25% blasts consistent with diagnosis of leukemia). Immunophenotyping and cytochemistry is then used to differentiate ALL from acute myeloid leukemia (AML) and identify T-cell or B-cell phenotype.
- Lumbar puncture is also performed for CSF analysis for lymphoblasts.
- Immunophenotyping
 - B cell: CD 10+, 19+, 20+, 22+, TdT+
 - Pre T cell: CD 3+, 5+, 7+, TdT+
 - Myeloid markers: CD 13+, 33+, 34+ (in minority)
 - CNS I: No detectable blasts
 - CNS 2: <5 WBC/ μ L, blasts present
 - CNS 3: \geq 5 WBC/ μ L, and blasts or symptoms of CNS leukemia)

DIFFERENTIAL DIAGNOSIS

- Infectious: infectious mononucleosis, Epstein-Barr virus (EBV), pertussis, parapertussis, parvovirus; cytomegalovirus (CMV), acute infectious lymphocytosis
- Juvenile rheumatoid arthritis
- Hematologic: immune thrombocytopenic purpura (ITP), aplastic anemia, Evans syndrome (ITP and autoimmune hemolytic anemia)
- Malignant disorders: round blue cell tumors with bone marrow involvement (neuroblastoma, rhabdomyosarcoma, Langerhans cell histiocytosis, lymphoma, retinoblastoma), myelodysplastic syndrome, AML, chronic myeloid leukemia (CML)

TREATMENT

- Patient suspected with ALL must be referred to a pediatric oncologist as soon as possible for further evaluation and management.
- Initial emergent stabilization may be required in case of
 - Hyperleukocytosis, defined as a WBC \geq 100,000/ μ L
 - Tumor lysis syndrome with renal insufficiency
 - Spinal cord compression
- Mediastinal mass causing SVC syndrome

- Therapy is aimed at inducing permanent biologic and clinical remission and is divided into various phases. Many children and adolescents are enrolled on clinical trials through the Children's Oncology Group or local institution. Treatment is standardized by prognostic indicators and provided by highly specialized teams with expertise in childhood cancer.
 - Induction (first 28–35 days). Typically includes the following drugs:
 - A glucocorticoid (prednisone or dexamethasone)
 - Vincristine
 - L-asparaginase
 - Anthracycline (in high-risk patients only)
 - Intrathecal chemotherapy (initial dose of cytarabine; subsequent treatment with methotrexate)
 - Consolidation: focuses on CNS prophylaxis; weekly intrathecal chemotherapy with
 - Low/average-risk patients: weekly vincristine, oral 6-mercaptopurine (6-MP), L-asparaginase, intensified with cyclophosphamide and cytarabine in certain subsets of patients
 - High-risk patients: more intensive systemic therapy with cyclophosphamide, cytarabine, methotrexate, vincristine, and L-asparaginase
 - Patients with initial involvement of the CNS or testes may receive radiation during this phase.
 - Interim maintenance: similar to maintenance therapy but more intensified
 - Vincristine, methotrexate, L-asparaginase
 - Intrathecal methotrexate
 - Delayed intensification: (reintensification and reconsolidation)
 - Combination of intensive therapy similar to induction and consolidation
 - Maintenance: continuation of therapy (lasts for 2–3 years)
 - Daily 6-MP, weekly oral methotrexate, pulse glucocorticoids, and vincristine with periodic intrathecal chemotherapy
- Ph+ patients t(9;21) receive continuous tyrosine kinase inhibitors

(imatinib or dasatinib)

- Patients with CNS and testicular involvement get prophylactic and therapeutic radiation therapy.
- Patients with Down syndrome and ALL have increased treatment-related morbidity and mortality and require some treatment modifications.
- Very high-risk patients may be treated with bone marrow transplant, following remission induction.
- Length of treatment from 2 to 3.25 years, depending on protocol and gender

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Early intensification has led to an increase in relapse-free survival.

Patient Monitoring

After completion of therapy:

- CBC, complete metabolic panel with LDH, liver and renal function tests every month for the 1st year, every 2 months for the 2nd year, then every 3 months for the 3rd year, every 6 months for the 4th year, and yearly thereafter
- Cardiac evaluation every year, dependent on cumulative dose of anthracycline and possible radiation scatter
- Endocrine evaluation close to puberty, especially in children who have received cranial or testicular radiation
- Monitor for late effects in cancer survivors clinic.

PROGNOSIS

- Long-term survival
 - Overall: approaches 90%
 - Low-risk patients: 90–95%
 - Standard risk group: 85%
 - High-risk group: 60–75%
 - Very high-risk group: ~20–50%
 - Infant group: 50%

COMPLICATIONS

- Bone marrow suppression (anemia and thrombocytopenia requiring transfusion support, possible transfusion-related infection or iron overload)
- Neutropenia leading to increased risk of infection
- L-asparaginase: anaphylaxis, pancreatitis, thrombosis, stroke
- Anthracyclines (daunorubicin and doxorubicin): cardiac toxicity, secondary AML
- Intrathecal methotrexate: neurotoxicity (frequently reversible)
- Steroids: avascular necrosis of bone, decreased bone density
- Cranial radiation: secondary brain tumors, growth retardation, learning difficulties and/or cognitive impairment
- Testicular radiation: lack of pubertal development, sterility
- Relapse
 - Approximately 10–30% of children and adolescents with ALL will relapse, usually within 5 years of diagnosis.
 - If relapse occurs while the patient is receiving therapy, outcomes are poor (<20%) even with systemic retreatment and possible bone marrow transplant (BMT).
 - If relapse occurs >36 months from diagnosis or is isolated to an extramedullary site such as the CNS or testis, survival is improved to 40–70% with systemic chemotherapy and possible focal radiation therapy.

CODES

ICD10

- C91.00 Acute lymphoblastic leukemia not having achieved remission
- C91.01 Acute lymphoblastic leukemia, in remission
- C91.02 Acute lymphoblastic leukemia, in relapse

FAQ

- Q: Can a child on treatment for ALL go to school or leave the house?
- A: Yes. Most centers encourage the child to live a normal life, including school, activities, and travel.
- Q: Will hair fall out and will the child be sick for ALL 3 years on chemotherapy?
- A: The hair usually falls out within a few weeks of initiating therapy and grows back when maintenance therapy begins (6–8 months). Most children feel relatively well during therapy, especially maintenance chemotherapy, and can resume a lot of normal activities.
- Q: Does the child need to be isolated from other children?
- A: The most serious infections a child on chemotherapy gets come from bacteria that the child is already colonized with, not community-acquired viruses. That being said, the child should be isolated from any child who has varicella or other known symptomatic infection.

ACUTE MYELOID LEUKEMIA

Allison Ast • William B. Slayton • David T. Teachey

BASICS

DESCRIPTION

- Acute myeloid leukemia (AML) results from a block in differentiation and unregulated proliferation of myeloid progenitor cells.
- AML is classified according to the World Health Organization (WHO) classification (2008).
- Formerly classified by French-American-British (FAB) classification
- WHO classification is based on genetic alterations, whereas FAB is based on morphology.

EPIDEMIOLOGY

- AML is the 7th most common pediatric malignancy.
- Leukemia that occurs in first 4 weeks of life is usually AML.
- Ratio of AML to acute lymphoblastic leukemia (ALL) throughout childhood is 1:5.
- Boys and girls are equally affected.
- Rates are highest in Asian and Pacific Islanders followed by Hispanics, Caucasians, and African Americans.

Incidence

- AML incidence peaks in infants younger than 1 year of age and again in children 10–14 years of age.
- Around 500 children/year in the United States

RISK FACTORS

Genetics

- 20–30% of pediatric blasts have normal karyotype versus 40–50% in adults.
- 60% of abnormal karyotypes fall into known subgroups.
- Translocations or duplications of the MLL gene at 11q23 or monosomy 7 carry a poor prognosis.
- These genetic abnormalities are found in many cases of therapy-

induced AML.

- FLT3-ITD with high allelic ratio, a drug targetable lesion, has been recently shown to carry a poor prognosis.
- Translocations t(8;21), t(15;17), and inv(16), as well as NPM and CEPB α mutations carry a good prognosis.
- AML associated with Down syndrome has an excellent prognosis.
- Certain congenital syndromes that carry an increased risk of AML:
 - Fanconi anemia
 - Bloom syndrome
 - Neurofibromatosis type I
 - Down syndrome
 - Severe congenital anemia (i.e., Kostmann disease treated with granulocyte colony-stimulating factor)
 - Diamond-Blackfan anemia
 - Paroxysmal nocturnal hemoglobinemia
 - Li-Fraumeni syndrome
 - Shwachman-Diamond syndrome
 - Dyskeratosis congenita
 - Noonan syndrome (RASopathies)

PATHOPHYSIOLOGY

- Principal defect is a block in the differentiation of primitive myeloid precursor cells.
- 2 mechanisms predominate:
 - Defect at the level of transcriptional activation
 - Defects in the signaling pathway of hematopoietic growth factors. For example, the proto-oncogene Ras is mutated in up to 1/3 of patients with AML.

ETIOLOGY

- Exact cause unknown in most cases.
- Acquired risk factors include the following:
 - Exposure to benzene
 - Exposure to ionizing radiation
 - Therapy induced, from chemotherapy for a prior malignancy
 - Alkylating agents such as cyclophosphamide, nitrogen mustard,

chlorambucil, and melphalan (typically presents several years after therapy)

- Epipodophyllotoxins such as VP16, VM26 (typically occurs within 2 years after therapy and is characterized by rearrangements involving 11q23)

DIAGNOSIS

HISTORY

Children with AML can present with very few symptoms or with life-threatening sepsis or hemorrhage. Common symptoms include the following:

- Fever: 30–40%
- Pallor: 25%
- Weight loss/anorexia: 22%
- Fatigue: 19%
- Bleeding (i.e., cutaneous, mucosal, menorrhagia): 33%
- Bone or joint pain: 18%

PHYSICAL EXAM

- Signs of anemia:
 - Pallor
 - Fatigue
 - Headache
 - Dyspnea
 - Systolic flow murmur
- Signs of thrombocytopenia:
 - Petechiae
 - Bruising
 - Epistaxis
 - Gingival bleeding
- Signs of infection:
 - Fever
 - Bacterial infections of lung, sinuses, gingiva, perirectal area, skin
- Other exam findings:

- Hepatomegaly
- Splenomegaly
- Lymphadenopathy
- Gingival hyperplasia
- Papilledema, cranial nerve palsies (rare)
- Colorless or slightly purple subcutaneous nodules: “blueberry muffin” lesions of leukemia cutis (more commonly seen in neonates)
- Chloroma is an extramedullary collection of leukemic cells that can present as a mass

DIAGNOSTIC TESTS & INTERPRETATION

Techniques such as fluorescence in situ hybridization, flow cytometry Southern blotting, and reverse transcriptase-polymerase chain reaction are used to diagnose and classify AML.

Lab

- CBC
 - Anemia, thrombocytopenia, elevated or low total WBC peripheral smear
 - Circulating myeloblasts may be seen.
- Prothrombin time (PT)/partial thromboplastin time (PTT), fibrin split products
 - Elevated in some cases, especially with acute promyelocytic leukemia (M3)
 - Can have severe, life-threatening disseminated intravascular coagulation (DIC)
- Electrolytes (abnormalities associated with tumor lysis syndrome)
 - Hyperkalemia
 - Hypocalcemia
 - Hyperphosphatemia
 - Hyperuricemia
- CSF analysis for cell count and cytology:
 - >5 WBC/ μ L is suggestive of CNS disease.
 - 5–15% of cases have CNS involvement at diagnosis.

Diagnostic Procedures/Other

Bone marrow aspirate:

- >20% myeloblasts is typically seen.
- To differentiate between AML with low blast count and myelodysplastic syndrome, serial bone marrow aspirates and biopsies are required as well as detailed cytogenetic analysis.
- At diagnosis, morphology, cytochemistry, immunophenotyping, and molecular and cytogenetics of the bone marrow aspirate are required.

Pathologic Findings

- Immunophenotyping
 - Precursor stage: CD34, CD117
 - Myelomonocytic markers: CD11B, CD11C, CD13, CD14, CD15, CD33, CD64, CD65, i-lysozyme
 - Lymphoid markers: T and B cell markers may be present on 30–60% of pediatric blasts.
 - CD41, CD42, and CD61 (megakaryocytic): particularly prevalent in patients with Down syndrome
- Morphology
 - Large blasts with low nuclear/cytoplasmic ratio
 - Multiple nucleoli and cytoplasmic granules
- Cytochemistry
 - Blasts are positive for myeloperoxidase and Sudan Black and usually negative for periodic acid–Schiff (PAS) and terminal deoxynucleotide transferase (TdT).

DIFFERENTIAL DIAGNOSIS

- Myeloid blast crisis of chronic myeloid leukemia (Philadelphia chromosome positive)
- Transient myeloproliferative disorder of the newborn (in Down syndrome)
- ALL
- Leukemoid reaction
- Exaggerated leukocytosis
- Myelodysplastic syndrome

TREATMENT

MEDICATION

- Patients are treated with 6–9 months of intensive chemotherapy given in cycles.
- The most effective drugs for remission induction in AML combine anthracyclines (e.g., doxorubicin, daunorubicin, daunomycin, and mitoxantrone) and cytarabine (Ara-C).
- Other agents sometimes used in combination chemotherapy include etoposide (VP-16), gemtuzumab (anti-CD33 monoclonal antibody), fludarabine, dexamethasone, L-asparaginase, and 6-thioguanine.
- Patients with acute promyelocytic leukemia can be cured with all-trans-retinoic acid and arsenic.
- Intrathecal Ara-C for CNS prophylaxis
- FLT3 inhibitors including sorafenib are being used in some patients with FLT3-ITD.
- Hematopoietic stem cell transplant is recommended for patients with high-risk cytogenetics (monosomy 7, monosomy 5, 5q-, FLT3-ITD) or those whom not in remission following 2 courses of induction therapy

ADDITIONAL TREATMENT

General Measures

- Hydration, alkalization, and allopurinol during induction
- Consider rasburicase in patients with marked elevations in uric acid and renal compromise (contraindicated in patients with G6PD deficiency).
- Blood product support
 - Avoid products from family members as sensitization can lead to poor engraftment after allogeneic bone marrow transplant.
- Broad-spectrum antibiotics and antifungal therapy for fever and neutropenia
- Prophylactic trimethoprim-sulfamethoxazole for *Pneumocystis* infection

ADDITIONAL THERAPIES

Allogeneic bone marrow transplant is recommended for high-risk AML in first remission.

INPATIENT CONSIDERATIONS

Initial Stabilization

Children with suspected AML should have immediate evaluation with physical exam, history, and laboratory data including CBC, PT/PTT, electrolytes, calcium, phosphorus, uric acid, and creatinine.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Blood counts monthly for 1st year, every 4 months for the 2nd year, and every 6 months thereafter
- Liver and kidney function tests every 3–6 months
- Cardiac function every 12 months.
- Endocrine function should be tested in pubertal children.

PROGNOSIS

- 85% achieve remission with intensive chemotherapy.
- ~60–70% achieve long-term survival (>5 years after diagnosis).
- Factors associated with poor prognosis:
 - WBC count >100,000/ μ L
 - Monosomy 7, monosomy 5 or del(5q)
 - Secondary AML or prior myelodysplastic syndrome
 - FLT3-ITD
 - Presence of multiple other genetic translocation events or mutations
 - Poor initial response to therapy (induction failure or presence of >0.1% minimal residual disease [MRD] in the bone marrow at the end of induction)
 - MRD testing measures quantities of residual leukemia not seen on morphologic exam using flow cytometry or standard cytogenetics.

COMPLICATIONS

- Bleeding (usually secondary to thrombocytopenia)
- DIC occurs in some types of AML, including acute promyelocytic leukemia (M3).
- Treat bleeding aggressively with fresh frozen plasma and platelets.
- Other cytopenias require blood product support.

- Infection
 - 40% of patients are febrile at diagnosis.
 - Empiric antibiotic therapy must be started after blood cultures are obtained.
- Leukostasis
 - Intravascular clumping of blasts causing hypoxia, infarction, and hemorrhage
 - Usually occurs when WBC >200,000/ μ L
 - Brain and lung are commonly affected.
 - Leukapheresis or exchange transfusion may be indicated for patients who are symptomatic with extremely high blast counts.
- Tumor lysis syndrome
 - Refers to the metabolic consequences from the release of cellular contents of dying leukemic cells
 - Hyperuricemia can lead to renal failure.
 - Hyperkalemia, hyperphosphatemia, and secondary hypocalcemia can be life threatening.
 - Patients should be hydrated with fluid containing bicarbonate and given allopurinol.

CODES

ICD10

- C92.00 Acute myeloblastic leukemia, not having achieved remission
- C92.01 Acute myeloblastic leukemia, in remission
- C92.02 Acute myeloblastic leukemia, in relapse

FAQ

- Q: Is an indwelling line required for therapy?
- A: Always
- Q: Are repeated hospitalizations likely?
- A: Repeated hospitalizations are needed for chemotherapy and infectious complications.

ADENOVIRUS INFECTION

Jason Newland • Jessica Newman

BASICS

DESCRIPTION

Adenoviruses are ubiquitous, nonenveloped, double-stranded DNA viruses capable of causing respiratory tract disease and gastroenteritis.

EPIDEMIOLOGY

- Primary infection usually occurs early in life (by age 5 years) and is, most often, characterized by upper respiratory symptoms.
- Military trainees are especially susceptible to infection, probably due to crowded living conditions.
- Respiratory and enteric infections may occur at any time of year. In temperate climates, peaks tend to occur in winter months.
- Cause approximately 5% of all pediatric respiratory tract infections and 5–10% of pneumonias
- Transmission of respiratory disease occurs via infected droplets.
 - Transmission of enteric adenoviruses is via the fecal–oral route.
 - Transmission can less commonly occur via contact with infected conjunctiva.
- Outbreaks of pharyngoconjunctival fever have been associated with inadequately chlorinated swimming pools and shared towels.
- One of the most common causes of viral myocarditis in children and adults

Incidence

Peaks in the first 2 years of life

RISK FACTORS

Exposure to adenovirus

GENERAL PREVENTION

Precautions for hospitalized patients

Symptoms	Type of precautions
Respiratory disease	Contact and droplet
Gastrointestinal	Contact
Conjunctivitis	Contact

A live oral vaccine for prevention of acute respiratory tract disease is used in military personnel.

PATHOPHYSIOLOGY

Adenoviruses may cause a lytic infection or a chronic/latent infection. In addition, they are capable of inducing oncogenic transformation of cells, although the clinical significance of this observation remains unclear.

ETIOLOGY

There are at least 57 identified human serotypes classified into 7 species (species A to G).

COMMONLY ASSOCIATED CONDITIONS

- Respiratory infections
 - Upper respiratory tract infections: otitis media, common cold, pharyngitis
 - Lower respiratory tract infection: pneumonia, pertussis-like syndrome, croup, necrotizing bronchitis, bronchiolitis (serotypes 3, 7, and 21 predominant in pneumonia epidemics)
- Pharyngoconjunctival fever
 - Low-grade fever associated with conjunctivitis, pharyngitis, rhinitis, and cervical adenitis
 - 15% of patients may have meningismus.
 - Increased incidence in summer months
 - Common source outbreaks most often associated with type 3
- Epidemic keratoconjunctivitis
 - Bilateral conjunctivitis with preauricular adenopathy
 - May persist for up to 4 weeks
 - Corneal opacities may persist for several months.
 - Associated with types 8, 19, and 37
- Myocarditis preceding viral illness

- Present with cardiovascular collapse, congestive heart failure, respiratory distress, or ventricular tachycardia
- Prognosis is poor.
- High mortality; a large number require transplant, and a portion develop dilated cardiomyopathy.
- Hemorrhagic cystitis may cause microscopic or gross hematuria.
 - If present, gross hematuria persists on average for 3 days.
 - Often associated with dysuria and urinary frequency
 - More common in males than females
 - Associated with types 11 and 21
 - Can occur in both immunocompetent and immunocompromised hosts
- Infantile diarrhea
 - Watery diarrhea associated with fever
 - Symptoms may persist for 1–2 weeks
 - Associated with types 40, 41, and less often 31
- CNS infection epidemics (associated with outbreaks of respiratory disease) and sporadic cases of encephalitis and meningitis have been observed; often associated with pneumonia
- Immunocompromised hosts
 - Can cause disseminated disease including pneumonia, hepatitis, and gastroenteritis
 - Frequently observed in transplanted patients; up to 40% of pediatric human stem cell transplant recipients and in 5–10% of solid organ transplant recipients
 - Fatality rates much higher, up to 30–75% in hematopoietic stem cell transplant patients
- Miscellaneous: associated with intussusception (isolated in up to 40% of cases) and fatal congenital infection

DIAGNOSIS

HISTORY

- Fever
 - Nonspecific

- Rhinitis
 - Upper respiratory infection (URI)
- Laryngitis, sore throat
 - URI
- Nonproductive or croupy cough
 - Respiratory infection
- Headache, myalgias
 - CNS infection
- Hematuria (gross or microscopic), dysuria, urinary frequency
 - Hemorrhagic cystitis
- Watery diarrhea
 - Enteric adenovirus
- Conjunctivitis, rhinitis, exudative pharyngitis, and meningismus
 - Typical findings of adenovirus

PHYSICAL EXAM

- Pulmonary tachypnea, wheezing, rales
 - Pneumonia
- Tachycardia, tachypnea, gallop rhythm, hepatomegaly
 - Myocarditis
- Abdominal tenderness, distention
 - Gastroenteritis

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- CBC
 - Leukocytosis or leukopenia, often with left shift in the differential counts
- Erythrocyte sedimentation rate (ESR)
 - Often elevated
- Viral isolation
 - From nasopharyngeal secretions, urine, conjunctivae, or stool
- Viral identification
 - Observe viral antigen in infected cells by immunofluorescence, amplify genome by polymerase chain reaction.
 - Stool antigen enzyme immunoassay (EIA) test

- Highest yield from nasopharyngeal swab or stool
- Adenovirus polymerase chain reaction (PCR) may be helpful in narrowing differential diagnosis, especially regarding the immunocompromised host, and can be used for prognostic purposes.
- ECG
 - Low-voltage QRS
 - Low-amplitude or inverted T waves
 - Small or absent Q wave in V₅ and V₆

Imaging

- Echocardiogram for suspected myocarditis
 - Poor ejection fraction
- Chest x-ray
 - Bilateral patchy interstitial infiltrates (lower lobes) or enlarged heart
 - Cardiomegaly

DIFFERENTIAL DIAGNOSIS

- Respiratory infection
 - Influenza
 - Parainfluenza
 - Human metapneumovirus
 - Pertussis
 - Mycoplasma pneumonia
 - Bacterial pneumonia
 - Bocavirus
- Pharyngoconjunctival fever
 - Group A Streptococcus
 - Epstein-Barr virus
 - Parainfluenza
 - Enterovirus
 - Measles
 - Kawasaki disease
- Epidemic keratoconjunctivitis
 - Herpes simplex
 - Chlamydia
 - Enterovirus

- Myocarditis
 - Enteroviruses
 - Herpes simplex
 - Epstein-Barr virus
 - Influenza
 - Bacterial myocarditis
- Hemorrhagic cystitis
 - Glomerulonephritis
 - Vasculitis
 - Renal tuberculosis
- Infantile diarrhea
 - Rotavirus
 - Calicivirus (including norovirus)
 - Astrovirus
 - Salmonella
 - Shigella
 - Campylobacter
- CNS infection
 - Enterovirus
 - Herpes simplex virus
 - Mycoplasma
 - Bacterial meningitis

TREATMENT

GENERAL MEASURES

- Supportive care
- Monitor for secondary bacterial infections.
- Avoid steroid-containing ophthalmic ointments.

MEDICATION

First Line

- Cidofovir
 - Has been shown to have benefit in immunocompromised patients with disseminated disease, specifically in hematopoietic stem cell

- transplant (HSCT) patients, where a reduction in adenovirus-related mortality compared with historical controls has been reported
- However, a risk of developing a dose-limiting nephrotoxicity exists and optimal dosing is not known.
- Reducing immunosuppression in transplanted patients should be considered for those with adenovirus disease.
- Infusion of AdV-specific cytotoxic T cells or intravenous immunoglobulin (IVIG) may have some benefit in immunocompromised patients, particularly HSCT patients.

ONGOING CARE

PROGNOSIS

Most syndromes are self-limited in the immunocompetent host.

COMPLICATIONS

- Bronchiolitis obliterans (rare)
- Corneal opacities with visual disturbance (usually resolves spontaneously)
- Congestive heart failure
- Dilated cardiomyopathy

ADDITIONAL READING

- Bowles NE, Ni J, Kearney KL, et al. Detection of viruses in myocardial tissues by polymerase chain reaction: evidence of adenovirus as a common cause of myocarditis in children and adults. *J Amer Coll Cardiol*. 2003;42(3):466–472.

CODES

ICD10

- B34.0 Adenovirus infection, unspecified
- A08.2 Adenoviral enteritis
- B97.0 Adenovirus as the cause of diseases classified elsewhere

FAQ

- Q: Is there anything one can do to prevent these infections?
- A: Washing hands and avoiding contact with ill persons will help slow the spread of these infections.

ALCOHOL (ETHANOL) INTOXICATION

Ann B. Bruner

BASICS

DESCRIPTION

- Acute ingestion (accidental or intended) of alcohol, resulting in loss of inhibition, often associated with unruly/violent behavior, impaired judgment and/or coordination, diminished alertness/responsiveness, and sedation or coma
- Accidental ingestion is more common in toddlers and younger children.
- Frequency of intentional alcohol use increases with age.
- Alcohol–drug interactions are common because acute intoxication reduces hepatic clearance for other drugs, thereby increasing their serum concentrations.

EPIDEMIOLOGY

Alcohol is the most used drug by young people: 30% of 8th graders, 69% of 12th graders, and 81% of college students have consumed alcohol.

Prevalence

- 71% of high school students have consumed alcohol in their lifetime; 21% had their first drink before age 13 years; 39% had one drink in past 30 days; 54% of 12th graders and 13% of 8th graders have been drunk at least once.
- Underage (12–20 years old) drinkers are 3 times more likely than adults to use illicit drugs with alcohol.
- Over 90% of alcohol is consumed through binge drinking; prevalence of binge alcohol use (>5 drinks once in past 2 weeks) in 2012 was 5% of 8th graders, 16% of 10th graders, 24% of 12th graders, 37% of college students, and 36% of young adults.
- 24% of high school students have ridden in a car driven by someone who had been drinking alcohol; 8% had driven a car when they had been drinking.

- 56% of college students mixed energy drinks with alcohol in the past month.
- Household products (medicinal, cosmetic, cleaning, hygiene) can contain up to 100% ethanol; rates of accidental exposure to and intentional intoxication from hand sanitizers are increasing.

RISK FACTORS

Patients with psychiatric conditions are at an increased risk for abuse of alcohol and other drugs.

GENERAL PREVENTION

- Promote family discussions about alcohol use and abuse.
- Provide safety recommendations to prevent accidental ingestions.

PATHOPHYSIOLOGY

- Effects of alcohol ingestion are related to dose, the time in which alcohol was consumed and then absorbed, and the patient's history of alcohol exposure; peak serum concentrations occur 30–60 minutes after ingestion.
- Alcohol absorption, decreased by the presence of food in the stomach and increased if liquid is carbonated, occurs rapidly and largely in the small intestine.
- Minimal quantities of alcohol are excreted in urine, sweat, and breath.
- >90% of alcohol oxidized in liver follows zero-order kinetics, primarily by alcohol dehydrogenase (ADH) and then acetaldehyde dehydrogenase (ALDH); rate of metabolism is fixed (not related to dose or time) and is proportional to body weight. Ethnic/racial and gender variabilities exist on quantity and efficacy of ADH.
- Ethanol is metabolized by ADH to acetaldehyde, then to acetate, and finally to ketones, fatty acids, or acetone; ketosis and, infrequently, metabolic acidosis can occur.
- Respiratory acidosis can occur secondary to carbon dioxide retention from respiratory depression due to ethanol intoxication.
- Hypoglycemia occurs during acute ethanol intoxication due to impaired gluconeogenesis resulting from changes in the NADH/NAD⁺ ratio associated with ethanol metabolism.
- Alcohol affects the CNS primarily through the γ -aminobutyric acid

(GABA) and glutamate neurotransmitter systems.

ETIOLOGY

Alcohol is produced from fermentation/distillation of sugar from grapes (wine), grains/corn (beer/whiskey), potatoes (vodka), or sugar cane (rum) then mixed into solution to make specific beverages; products are marketed according to alcohol content or proof (twice the percent).

Alcohol content ranges from 3–6% (6–12 proof) in beer to 40–75% (80–150 proof) in vodka/rum/whiskey. Alcohol is often consumed concurrently with other substances (licit and illicit), presenting a mixed clinical picture of intoxication.

COMMONLY ASSOCIATED CONDITIONS

- Alcohol is involved in 30% of all drug overdoses.
- A significant percentage of adolescent trauma patients, especially victims of gunshot wounds, have positive toxicology screens for alcohol and other drugs. Ethanol use increases trauma risk by 3- to 7-fold.

DIAGNOSIS

HISTORY

- Medical: Baseline health will affect patient's response to alcohol; diabetics, for example, may have worse hypoglycemia.
- Type and dose of other drugs ingested:
 - Clinical effects of and treatment for other ingestions can vary depending on substance.
 - Polysubstance ingestion is very common.
- Psychiatric history: Evaluate for possible suicidal ideation.
- Gathering details regarding the alcohol consumed (type, amount, and over what time period) may help predict clinical course. For example, blood alcohol concentration (BAC) may continue rising if ingestion occurred recently.
- Intoxication presents clinically with signs ranging from lack of coordination, slurred speech, and confusion (BAC of 20–200 mg/dL) to ataxia and nausea/vomiting (BAC 200–300 mg/dL) to amnesia,

seizures, or coma (BAC >300 mg/dL).

PHYSICAL EXAM

- Bruises, lacerations, and fractures may suggest trauma and raise concern about CNS injury.
- Neurologic exam, including mental status, will assess degree of intoxication and consciousness, including patient's ability to protect his or her airway, and risk for aspiration.
- Tachycardia and hypotension may indicate dehydration.
- Fever may suggest infection.
- Average time for normalization of mental status in intoxicated adults is 3–3.5 hours; patients without clinical improvement in 3 hours should be evaluated for other causes of altered mental status.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- BAC
 - Generally correlates with clinical picture
 - In children, signs of intoxication may be present at levels of 50 mg/dL.
 - Serum levels of 600–800 mg/dL can be fatal.
- Blood and/or urine toxicology screen
 - Most urine toxicology screens do not test for alcohol.
 - Concurrent ingestions are common.
- Acetaminophen level
 - Usually not part of the general serum toxicology screen
 - Consider if polysubstance ingestion suspected and/or if patient has suicidal ideation
- Serum electrolytes
 - Alcohol is a diuretic. The associated nausea and vomiting seen with intoxication may result in severe dehydration.
 - Ketosis and, infrequently, metabolic acidosis can occur.
- Serum glucose level: Ethanol inhibits gluconeogenesis and can be associated with hypoglycemia.
- Blood gas can show both respiratory and metabolic acidosis.

DIFFERENTIAL DIAGNOSIS

- Environmental
 - Other ingestions (overdose of sedatives or illicit drugs, such as benzodiazepines, marijuana, narcotics, lysergic acid diethylamide [LSD], and phencyclidine [PCP])
 - Toxic exposures (ethylene glycol, methanol, carbon monoxide)
 - Head trauma
- Infection
 - Meningitis
 - Encephalitis
 - Sepsis
- Tumor: brain tumor
- Metabolic
 - Hypoglycemia
 - Ketoacidosis
 - Hyperammonemia
 - Electrolyte imbalances (hyponatremia, hypernatremia)
- Miscellaneous
 - Increased intracranial pressure from hydrocephalus, mass, other
 - Stroke

TREATMENT

MEDICATION

IV dextrose as needed for hypoglycemia

ADDITIONAL TREATMENT

General Measures

- Assess airway, breathing, and circulation (ABC).
- Protect airway: The patient may require intubation and mechanical ventilation.
- Mainstay is supportive therapy as no specific ethanol antidote exists.
- Appropriate trauma management as needed
- Because alcohol is absorbed rapidly, gastric lavage is indicated only if the patient is seen immediately after ingestion (within minutes).

ISSUES FOR REFERRAL

- Refer to substance abuse specialist (addiction medicine, psychiatrist, or certified addictions counselor) for detailed evaluation and treatment.
- Refer for psychiatric evaluation if depression, anxiety, suicidal ideation, or any other mental health condition is suspected.
- Assess for other risk-taking behaviors—including other substance use, sexual activity, use of motor vehicles while intoxicated, weapon carrying, and delinquency—and their sequelae, including pregnancy, sexually transmitted infections, and violence.

INPATIENT CONSIDERATIONS

Initial Stabilization

Keep patient awake; watch for vomiting as patients are at risk for choking owing to depressed gag reflex.

Admission Criteria

- Unstable vital signs (hypotension)
- Persistent CNS depression/impaired mental status
- Potential severity of comorbid psychiatric conditions (depression/suicidality)
- Inability to contact a parent/guardian

IV Fluids

IV fluids for dehydration and hypotension

Nursing

Observe and monitor vital signs and neurologic status.

Discharge Criteria

- Stable vital signs
- Patient awake, alert, responsive, and oriented
- Decreasing BAC
- Parent/guardian fully informed about patient's alcohol use

DIET

NPO secondary to depressed gag reflex

PROGNOSIS

BAC serum levels of 600–800 mg/dL can be fatal.

COMPLICATIONS

- Diuresis and dehydration
- Vasodilation and hypotension
- Vomiting, aspiration, potential respiratory arrest
- Hypoglycemia
- Metabolic acidosis
- Impaired mental status
- Engagement in risk-taking behaviors (e.g., other drug use, unprotected intercourse) while intoxicated
- CNS depression
- Gastritis
- GI bleeding
- Acute pancreatitis
- Motor vehicle collisions associated with driving while intoxicated
- Alcoholism
- Alcohol withdrawal following a period of intoxication in chronic users (symptoms include tachycardia, elevated blood pressure, irritability, nausea, vomiting, and tremor)

CODES

ICD10

- F10.929 Alcohol use, unspecified with intoxication, unspecified
- T51.0X4A Toxic effect of ethanol, undetermined, initial encounter
- F10.920 Alcohol use, unspecified with intoxication, uncomplicated

FAQ

- Q: How quickly is alcohol metabolized?
- A: The liver metabolizes ~10 g of ethanol per hour, which corresponds to a decline in BAC of 18–20 mg/dL/h.
- Q: What is binge drinking in youth?
- A: For children 9–13 years old and girls 14–17 years old, 3 or more drinks; for boys 14–15 years old, 4 or more
- Q: Are younger children at any increased risk from alcohol poisoning?
- A: Ethanol inhibits gluconeogenesis; younger children have an increased risk of hypoglycemia because they have relatively smaller hepatic glycogen stores; however, children tend to have more rapid clearance rates (up to 30 mg/dL/h).

ALLERGIC CHILD

Barry Pelz • Anne Marie Singh

BASICS

Allergic diseases include atopic dermatitis, food allergy, asthma, and allergic rhinitis. Atopic or allergic diseases are becoming more and more prevalent in the population.

- Food allergy in its most severe form may manifest as anaphylaxis.
- The conditions may present in a variety of ways as described below.

DESCRIPTION

- Atopic dermatitis
 - Atopic dermatitis (or eczema) is characterized by chronic, relapsing, pruritic inflamed skin which is often erythematous, xerotic, and/or excoriated.
 - Atopic dermatitis may occur in isolation without other atopic diseases.
 - Atopic dermatitis may also be the beginning of the “atopic march” in which atopic dermatitis precedes the onset of other atopic conditions which may include food allergy, asthma, and allergic rhinitis.
- Urticaria
 - Refers to hives or the erythematous wheals that occur when histamine is released from mast cells
 - May be caused by a number of triggers
 - Viral infection is the most common cause of urticaria in children.
 - The allergic child may develop urticaria when an antigen such as a food or animal dander causes IgE-mediated release of mast cell mediators.
- Food allergy
 - Presents with an IgE-mediated reaction after exposure to a food to which the child is sensitized
 - Reactions may present with any number of symptoms, including urticaria, lip or tongue swelling, closing of the throat, wheezing,

shortness of breath, repeated vomiting after allergen ingestion, diarrhea, or any combination of the above.

- The most common food allergens include cow's milk, egg white, peanut, tree nuts, wheat, soy, fish, and shellfish.
- Food allergy should be distinguished from food intolerance which has a nonimmunologic basis and does not carry a risk of anaphylaxis.
- Asthma
 - An obstructive airway disease characterized by recurrent wheezing, bronchoconstriction, increased mucous production, and airway inflammation
 - Asthma is one of many potential causes of wheezing in children.
 - Wheezing with RSV and human rhinovirus infection are risk factors for the development of asthma.
- Allergic rhinitis
 - A condition in which children are sensitized to perennial allergens, seasonal allergens, or both
 - Perennial allergens include dust mite, molds, cockroach, and animal dander.
 - Seasonal allergens include tree pollens, grass pollens, or ragweed.
 - Rhinitis symptoms may include watery eyes, itchy eyes, rhinorrhea, nasal discharge, itchy nose, postnasal drip, headache, sinus pressure, nasal obstruction, mouth breathing, or snoring.
 - Symptoms may be seasonal, year-round, or triggered by exposure to specific allergens (such as cats or dogs).

RISK FACTORS

Genetics

- Children who do not have a family history of atopy have approximately 25% chance of being atopic.
- For children with at least one parent who is atopic, the risk of atopy approximately doubles compared to the general population.

PATHOPHYSIOLOGY

Most of these allergic conditions are IgE mediated, and all of them result from a complex interaction between multiple genetic and environmental

factors.

DIAGNOSIS

A thorough history and physical examination are the keys to diagnosing the allergic child.

HISTORY

- History should elicit signs and symptoms of allergic diseases while at the same time exploring other potential etiologies for the child's symptoms.
- The allergic child should have symptoms of atopic dermatitis, urticaria, wheezing, reactions to foods, or symptoms of rhinitis such as sneezing, itchy eyes, watery eyes, itchy nose, runny nose, or itchy throat.
- The practitioner should also review the family history as atopic disease often runs in families.

PHYSICAL EXAM

A complete physical exam is essential to rule out systemic diseases that can mimic allergic disease.

- **Finding:** Ocular signs may include the following:
 - Dark circles under the eyes or the so-called “allergic shiners” which result from venous stasis secondary to passive congestion in the nose, impeding venous return to the vessels under the eyes
 - Cobblestoning of the conjunctiva
 - Erythematous injection of the conjunctiva
 - Dennie-Morgan lines or infraorbital folds associated with suborbital edema secondary to chronic inflammation from atopic dermatitis
 - Clear stringy ocular discharge
- **Finding:** Nasal allergic signs may include the following:
 - Pale edematous nasal mucosa
 - Clear nasal discharge with or without occlusion
 - Nasal crease across the bridge of nose secondary to repeated upward rubbing of the nose from “the allergic salute”
 - Nasal polyps may be present, although they are much more common in adults and should prompt consideration of diseases such

as cystic fibrosis when seen in children.

- **Finding:** Ear allergic signs may include the following:
 - Fluid in the middle ear or retracted tympanic membranes
 - Eustachian tube dysfunction associated with allergic inflammation
- **Finding:** Throat allergic signs may include the following:
 - Cobblestoning of the posterior pharynx secondary to submucosal lymphoid hyperplasia
- **Finding:** Lung allergic signs may include the following:
 - Wheezes, rhonchi, decreased air entry, prolonged expiration, and chronic obstruction secondary to allergic responses
- **Finding:** Skin allergic signs may include the following:
 - Eczema, hives, angioedema, and dermatographism

DIFFERENTIAL DIAGNOSIS

The differential for allergic diseases is extensive and should focus on considering other etiologies for the symptoms.

- Ear/nose symptoms
 - Eye findings may be caused by physical or chemical irritants or by viral or bacterial infection.
 - Allergic rhinitis symptoms may resemble upper respiratory infections, sinusitis, nasal foreign bodies, or nonallergic rhinitis.
 - A number of medications can also lead to rhinitis medicamentosa, or symptoms of nasal congestion due to medication use.
 - Systemic diseases such as cystic fibrosis, immotile cilia syndrome, Kartagener syndrome, or immunodeficiencies may present with recurrent nasal symptoms and/or with lung symptoms.
 - Lung symptoms may be caused by physical or chemical irritants including tobacco smoke, environmental pollution, and inhalants.
- Chest symptoms
 - Lung symptoms may also result from gastroesophageal reflux leading to (nocturnal) cough.
 - Foreign body aspiration may produce lung symptoms and auscultatory signs, although typically, foreign bodies create more focal lung findings.
 - Anatomic defects in the airway may also result in symptoms that are similar to allergic symptoms.

- Skin symptoms
 - Skin findings may be caused by a number of etiologies including irritant dermatitis, viral exanthems, autoimmune disorders, bacterial, fungal, or parasitic infections.
- Multisystem
 - Anaphylaxis may sometimes be confused with angioedema, vocal cord dysfunction, globus hystericus, or with other causes of shock (sepsis, hypovolemia, cardiogenic).
 - Food allergy may sometimes be confused with food intolerance, but food intolerances present with abdominal discomfort, bloating, flatulence, or nonspecific malaise, whereas food allergy presents with true IgE-mediated reactions.

DIAGNOSTIC TESTS & INTERPRETATION

The diagnosis of allergic diseases can be strongly suggested based on history and physical alone. Specific tests can be done by a specialist in allergy and immunology in order to be properly interpreted. Often, initial therapy can be initiated without definitive tests.

Once the allergic child is referred to the allergist, testing may include the following:

- Immediate hypersensitivity testing
 - Skin prick tests to suspected allergens based on history may demonstrate IgE sensitization if positive.
 - Intradermal skin tests for patients who have a negative skin prick test and a suspicious history pose a greater risk of systemic reactions but can be done for environmental allergens, not for foods.
- Blood-specific IgE testing
 - ImmunoCAP tests measure free serum IgE to a specific antigen to which a particular patient may be sensitized.
 - Although panels are available, these tests are best done for targeted potential allergens that are suggested by the history and should be interpreted by an allergist with experience in interpreting and guiding therapy.
 - Incorrect use or interpretation of ImmunoCAP testing may result in inappropriate dietary restrictions, nutritional deficits, and undue anxiety.

- ImmunoCAP levels may be trended over time to help monitor for the development of tolerance.
- Eosinophilia
 - Eosinophils in the blood (on a CBC) or in respiratory secretions or nasal samples may be indicative of an allergic diathesis.
- Pulmonary function tests (PFTs)
 - PFTs or spirometry should be obtained on asthmatic children or in children with respiratory allergic histories to evaluate for obstructive diseases.

TREATMENT

GENERAL MEASURES

- The main principle of therapy for allergic diseases is avoidance of allergic triggers.
- For atopic dermatitis, general treatment measures include measures to help lock moisture into skin, treat inflammation when present, control pruritus, minimize skin irritants, and treat infection when present.
- For food allergy, the most important therapeutic measure is strict avoidance of the food that causes the allergy in order to prevent an allergic reaction.
 - Children at risk for a reaction to a food allergen should be prescribed an epinephrine autoinjector to use in the event of systemic symptoms or anaphylaxis.
 - An emergency action plan should be provided, reviewing the signs and symptoms of a reaction and the doses and medications that should be used in the event that an accidental ingestion occurs.
- For allergic rhinitis, systemic antihistamines may be helpful in controlling symptoms. Many patients also benefit from intranasal corticosteroids when indicated.
 - Specific environmental control measures may be indicated based on specific skin testing results.
 - Pets should be kept out of the bedroom if a child has allergic stigmata due to animal dander.
 - To minimize exposure to dust mite allergen, the bedding should be

encased in dust mite encasements and washed in hot water at least once every 2 weeks.

- Immunotherapy may be indicated for patients with allergic rhinitis or venom allergy.
- For patients with asthma, treatment should follow the latest National Heart, Lung and Blood Institute (NHLBI) of the National Institutes of Health (NIH) asthma guidelines with consideration to the child's symptomatology, impairment, and risk. Therapies may include use of rescue inhalers, controller medications such as inhaled corticosteroids, leukotriene antagonists, and others (see [Appendix, Figure 5](#)). Control of comorbidities such as allergic rhinitis and GERD are also important therapeutic steps.

ISSUES FOR REFERRAL

- Any child with allergic symptoms may benefit from referral to an allergist-immunologist.
- A patient failing medical management of upper respiratory or ocular allergies with routine antihistamine/decongestant medications may be referred to an allergist who can help identify triggers contributing to the problem.
- Poorly controlled asthma not responding to intermittent inhaled β -agonists or an asthmatic child who is symptomatic between exacerbations or has an atypical pattern of exacerbations should be referred.
- Asthma patients with frequent hospitalizations or steroid dependence should be referred.
- Patients who are absent from school frequently because of allergic or asthmatic symptoms should be referred.
- Patients with food allergy, drug allergy, latex allergy, or difficult-to-manage atopic dermatitis should also be referred to an allergist.

ONGOING CARE

PROGNOSIS

- In general, environmental allergies that cause rhinitis and asthma

persist into adulthood.

- About 50% of milk-allergic children may outgrow their allergy by school age and about 80% by age 16 years. Those who tolerate baked milk seem to have a higher likelihood of outgrowing the allergy.
- About 60–80% of egg-allergic children may outgrow their egg allergy. Children who tolerate baked egg seem more likely to outgrow the allergy.
- Children may occasionally outgrow peanut, tree nut, or shellfish allergy.
- Allergic diseases may have a significant impact on the patient and family's quality of life and may lead to issues with anxiety and mental health.

CODES

ICD10

- L20.9 Atopic dermatitis, unspecified
- L27.2 Dermatitis due to ingested food
- J45.909 Unspecified asthma, uncomplicated

FAQ

- Q: Do children outgrow allergies?
- A: In general, environmental allergies that cause rhinitis and asthma persist into adulthood. However, most children outgrow food allergies to milk, egg, soy, and wheat. Children may occasionally outgrow peanut, tree nut, or shellfish allergies.
- Q: If a parent is allergic to a specific allergen, can the child inherit this allergy?
- A: Children inherit the tendency to be allergic, but they do not inherit specific allergies.
- Q: How can allergies be prevented?
- A: Allergy prevention is currently not possible, but research in this field is ongoing.

ALOPECIA (HAIR LOSS)

Hope Rhodes • Terry Kind

BASICS

DESCRIPTION

- Absence of hair where it normally grows
- Categorized as acquired or congenital
 - Most cases are acquired: Tinea capitis is most common, followed by traumatic alopecia and alopecia areata.
- Also categorized as diffuse or localized
 - Most cases of alopecia are localized and, of these, tinea capitis is the most common.
- Many normal healthy newborns lose their hair in the first few months of life.
 - Hair loss may be exacerbated by friction from bedding/sleep surface, especially in atopic infants.
- Normally, about 50–100 hairs are shed and simultaneously replaced every day.
- 90% of alopecia cases are due to the following disorders:
 - Tinea capitis
 - Alopecia areata
 - Traction alopecia
 - Telogen effluvium
 - Alopecia is preceded by a psychologically or physically stressful event 6–16 weeks prior to the onset of hair loss.
 - Growing hairs convert rapidly to resting hairs.

RISK FACTORS

Genetics

- Alopecia areata
 - Polygenic with variety of triggering factors
 - Family history in 10–42% of cases
 - Males and females equally affected
 - Onset usually before age 30 years

- Monilethrix (also called beaded hair)
 - A rare autosomal dominant disorder

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Consider the most likely diagnoses first.

- Infectious
 - Tinea capitis
 - Varicella
 - Syphilis
- Congenital
 - Aplasia cutis congenita
 - Incontinentia pigmenti
 - Oculomandibulofacial syndrome (sparse hair, hypoplastic teeth, cataracts, short stature)
 - Goltz syndrome (alopecia, focal dermal hypoplasia, strabismus, nail dystrophy)
 - Triangular alopecia of the frontal scalp
 - Focal dermal hypoplasia
 - Hair-shaft defects (trichodystrophies)
 - Ectodermal dysplasias
 - Nevi
 - Progeria
- Nutritional
 - Zinc deficiency
 - Marasmus
 - Kwashiorkor
 - Anorexia or bulimia
 - Hypervitaminosis A
 - Celiac disease
- Endocrinologic
 - Androgenetic alopecia
 - Hypothyroidism
 - Hyperthyroidism

- Hypoparathyroidism
- Hypopituitarism
- Diabetes mellitus
- Autoimmune
 - Alopecia areata
 - Systemic lupus erythematosus
 - Scleroderma
- Trauma
 - Traction alopecia
 - Trichotillomania
 - Scalp electrode scar from in utero monitoring
- Toxic exposures:
 - Antimetabolites
 - Anticoagulants
 - Antithyroid medications
 - Heavy metals (e.g., arsenic, lead)
 - Radiation
- Stress
 - Trichotillomania
- Miscellaneous:
 - Telogen effluvium
 - Darier disease (keratotic crusted papules, keratosis follicularis)
 - Lichen planus
 - Burn
 - Stress

COMMONLY ASSOCIATED CONDITIONS

- May be associated with a genetic, endocrine, or toxin-mediated condition
- Look for nail, skin, teeth, or gland involvement.
- Trichotillomania is frequently associated with a finger-sucking habit.

APPROACH TO PATIENT

- Treatment of alopecia is guided by underlying etiology.
- Systemic treatment is needed for tinea capitis; topical antifungals alone are not adequate. Selenium sulfide or ketoconazole shampoo is

recommended for tinea capitis to decrease fungal shedding and risk of spread to others.

- Other than reassurance and waiting, there is no proven effective long-term therapy for alopecia areata. Topical steroids may show short-term benefit. There are no randomized clinical trials on the use of topical immunotherapy or intralesional steroids.
- Caution regarding side effects of all potential treatments.

HISTORY

- Attempt to classify the alopecia. This will guide the diagnosis and treatment plan.
- **Question:** Is the loss acquired or congenital? Is the alopecia treatable? Is it likely to be self-limited?
- Significance: Consider most likely diagnoses, including tinea capitis, traumatic alopecia, and alopecia areata.
- **Question:** Associated abnormalities?
- Significance: may be part of a syndrome
- **Question:** Is there an endocrine abnormality or a toxin/medication effect?
- Significance: Some of these would require prompt attention.
- **Question:** Assess extent of hair loss.
- Significance:
 - Increased amount of hair in the brush or in the shower/tub drain?
 - Does hair appear or feel thinner?
 - Patches of hair loss or broken hairs noted?
- **Question:** Considering trichotillomania?
- Significance: Note that patients often deny hair-pulling. Direct confrontation is rarely helpful.

PHYSICAL EXAM

- Assess localized versus diffuse hair loss.
- **Finding:** appearance of the scalp
- Significance:
 - Alopecia areata: Except for well-demarcated hair loss, scalp appears normal with smooth surface.
 - Tinea capitis: Scalp is often scaly and may be erythematous; areas

of hair loss with broken hair stubs, referred to as black-dot alopecia.

- **Finding:** bizarre configuration and irregular border; hairs of varying lengths
- Significance: distinguishes traction/traumatic alopecia from alopecia areata
- **Finding:** short broken hairs but not black dots
- Significance: Short hairs are usually associated with trichotillomania, whereas black dot alopecia is seen with tinea capitis.
- **Finding:** frontal, vertex, or bitemporal decreased hair density in adolescents
- Significance: may be adolescent-onset, androgenetic alopecia
- **Finding:** Hair shaft varies in thickness, with small node-like deformities (like beads), increased breakage, and partial alopecia.
- Significance:
 - Monilethrix
 - Other hair-shaft abnormalities with increased fragility include pseudomonilethrix, trichorrhexis, pili torti, pili bifurcati, Menkes kinky hair syndrome, and trichothiodystrophy.
- **Finding:** associated systemic signs or any nonscalp findings
- Significance: may signify a genetic syndrome or endocrine abnormality
- **Finding:** nail defects such as dystrophic changes and fine stippling
- Significance:
 - Nail defects are seen in 10–20% of cases of alopecia areata.
 - Nail defects accompanying localized alopecia along with syndactyly, strabismus, and dermal hypoplasia may be found in Goltz syndrome.
 - In ectodermal dysplasias, nails, hair, teeth, or glands may be affected.
- **Finding:** pubic hair and eyebrow hair loss
- Significance:
 - Found in a form of alopecia areata called alopecia universalis, where nearly all body hair is lost (alopecia totalis involves the loss of all scalp hair)
 - Body hair loss such as pubic hair or eyebrow hair may also occur in trichotillomania.

DIAGNOSTIC TESTS & INTERPRETATION

- **Test:** fungal culture
- Significance:
 - Recommended when assessing for tinea capitis as a cause of alopecia
 - Definitive results may take up to several weeks; may treat while awaiting results
 - Using a cotton-tipped applicator, culturette, toothbrush, or direct plating on Sabouraud dextrose agar, culture will be positive for *Trichophyton tonsurans* in >90% of cases in North America.
 - Less common are *Microsporum canis*, *Microsporum audouinii*, *Trichophyton mentagrophytes*, and *Trichophyton schoenleinii*.
- **Test:** dermatophyte-testing medium (DTM)
- Significance:
 - Assessing for tinea capitis
 - Definitive results may take from days to weeks. If dermatophyte colonies grow on the medium, the phenol red indicator in the agar will turn from yellow to red.
- **Test:** Wood's light (lamp) examination
- Significance:
 - *M. canis*, *M. audouinii*, or *T. schoenleinii* fluoresces green.
 - *T. tonsurans* does not fluoresce.
- **Test:** potassium hydroxide (KOH) exam
- Significance:
 - The KOH exam is another way to assess for tinea capitis.
 - Hyphae and spores within hair shaft indicate tinea capitis.
 - With *Microsporum*, spores surround the hair shaft.
- **Test:** endocrine testing
- Significance:
 - Alopecia areata or diffuse alopecia is associated with several endocrine disorders (e.g., hyperthyroidism, diabetes).
 - Based on history of physical exam, consider relevant screening tests or referral to an endocrinologist or dermatologist for further evaluation.
 - Routine screening for autoimmune disorders is generally not

indicated.

- **Test:** hair-pluck test
- **Significance:**
 - Used to determine the ratio of telogen (resting) to anagen (growing) hairs
 - ~50 hairs are plucked (with 1 firm tug using a hemostat clamped around the hair ~1 cm from the scalp) and examined under the low-power lens of a microscope to determine the percentage of hairs that are telogen and anagen hairs.
 - >25% telogen hairs are indicative of telogen effluvium.
- **Test:** scalp biopsy
- **Significance:**
 - Can help to distinguish alopecia areata and trichotillomania
 - In alopecia areata, hair follicles become small but continue to produce fine hairs; there is mitotic activity in the matrix and often inflammation is present.
 - In trichotillomania, follicles are not small. They are usually in a transitional (catagen) phase and no longer produce normal hair shafts. Keratinous debris, fibrosis, and clumps of dark melanin pigment are present. Significant inflammation is absent.
 - In telogen effluvium, follicles remain intact without inflammation.

TREATMENT

MEDICATION

First Line

- For tinea capitis: microsize griseofulvin 20–25 mg/kg/24 h (maximum 1 g) or ultramicrosize griseofulvin 10–15 mg/kg/24 h (maximum 750 mg) orally once per day for 4–6 weeks; approved for children >2 years of age
- For alopecia areata requiring treatment: Topical corticosteroids may be used for isolated patches for short-term benefit.

Second Line

- For tinea capitis: Terbinafine, itraconazole, or fluconazole may be

effective, although only terbinafine is FDA-approved for this condition.

- For alopecia areata: There is limited evidence for long-term effectiveness of any treatment. For trial of other therapies (intralesional steroid, topical immunotherapy), seek consultation with a dermatologist.

General Measures

- Treatment of alopecia is guided by the underlying cause.
- If alopecia signifies a toxic exposure or an endocrine abnormality, the underlying condition may require prompt diagnosis and treatment.
- Infectious causes of alopecia (such as with tinea capitis) should be treated promptly.
- Most patients with alopecia areata do not need treatment, as regrowth will occur spontaneously.
- Complementary and alternative medicine (CAM):
 - Hypnotherapy, massage, acupuncture, and onion juice are among the complementary therapies that have been tried for conditions like alopecia areata and trichotillomania. Of note, although many patients try CAM for alopecia, more research is needed.

ONGOING CARE

PROGNOSIS

- Tinea capitis, alopecia areata, and traction alopecia
 - Hair will regrow, may take months.
 - There is a poorer prognosis with alopecia universalis. <10% have full recovery.
- Telogen effluvium
 - Spontaneous regrowth is expected unless the stressful event continues/recurs.
- Alopecia areata may spontaneously remit and then recur.

CODES

ICD10

- L65.9 Nonscarring hair loss, unspecified
- B35.0 Tinea barbae and tinea capitis
- L63.9 Alopecia areata, unspecified

FAQ

- Q: When can children with tinea capitis return to school?
- A: Once treatment with a systemic antifungal has begun, the child may return to school. A topical shampoo such as selenium sulfide or ketoconazole is recommended to decrease fungal shedding and the risk of spread.

- Q: Will the hair grow back?
- A: For the 3 most common causes of childhood alopecia—accounting for 90% of cases; tinea capitis, alopecia areata, and traction alopecia—hair will regrow, but may take months to do so.

ALPHA-1 ANTITRYPSIN DEFICIENCY

Christine K. Lee

BASICS

DESCRIPTION

- Alpha-1 antitrypsin (AAT) is a serine protease inhibitor and a 55-kd glycoprotein which is primarily synthesized in the liver and released into the circulation.
- AAT is the main inhibitor of neutrophil proteases, which can cause host tissue damage.
- AAT deficiency is an autosomal codominant genetic disorder that causes lung, liver, and skin disease.
- Classic PiZZ AAT deficiency is caused by homozygosity for Z mutant allele of AAT.
- Lung disease in AAT deficiency can develop after the 3rd decade of life and progress to emphysema.
- Liver disease may present as jaundice in infants or as elevated liver enzymes, portal hypertension, or cirrhosis in older patients.
- Skin disease is more rare and presents as necrotizing panniculitis in adults (mean age of onset is 40 years).

EPIDEMIOLOGY

Most common genetic cause of liver disease in children and of emphysema in adults

Incidence

- Incidence of the PiZZ genotype is highest in Caucasians in North America, Australia, and Europe, particularly in Scandinavia, British Isles, Northern France, and the Tyrol region of Italy.
- In the United States, the PiZ allele is found in ~14.5 per 1,000 people, with higher frequency in Caucasians and lower frequency in Asians, blacks, and Hispanics.
- The incidence of classic AAT deficiency (PiZZ) is 1 in 1,800–2,000 live births.

Prevalence

- It has been estimated that approximately 70,000–100,000 individuals are affected in the United States.
- Of these genetically affected individuals, fewer than 10% are estimated to have been diagnosed with AAT deficiency
- Approximately 25 million people in the United States are thought to be carriers of a mutant allele.

RISK FACTORS

Genetics

- AAT is a serine protease inhibitor encoded by the SERPINA1 gene, which is located on the long arm of chromosome 14.
- The normal allele is M, with over 100 variant alleles identified.
- The classic PiZZ genotype is the result of a point mutation at position 342 in the AAT gene, which encodes a substitution of lysine for glutamate
- The S allele (2nd most common mutation) occurs from a substitution of valine for glutamate at position 246.
- Patients with PiZZ alleles have serum AAT levels, which are less than 15% of normal.
- Heterozygous carriers of the Z allele are found in 1.5–3% of the population. In and of itself, this genetic mutation is not a cause of liver disease, but it may contribute to pathophysiology of other liver diseases.
- PiMS, PiMZ, and PiSS are also not directly associated with liver disease, although referral center data reports patients with chronic liver disease having a higher frequency of PiMZ than would be predicted by chance.
- The mutant S protein, when coexpressed with Z-protein, can form abnormal polymers leading to liver disease, which is identical to PiZZ patients.
- Because ~10% of affected PiZZ or PiSZ individuals have clinically significant liver disease, there may be other genetic or environmental factors which are important modifiers of AAT.

PATHOPHYSIOLOGY

- Lung disease in patients with PiZZ results from inadequate levels of AAT to protect the lungs from destructive enzymes, such as elastase, leading to early emphysema. This process is further worsened by exposure to cigarette smoke and environmental pollutants.
- Liver disease occurs from accumulation of the abnormal Z mutant protein within liver cells.
 - The mutant Z gene is transcribed, translated, and then translocated into the endoplasmic reticulum (ER).
 - Some molecules undergo proteolytic degradation, others aggregate to form large protein polymers, and few are secreted, leading to intrahepatocyte accumulation and thereby resulting in low AAT serum levels.
 - ER-associated degradation of mutant Z-protein is less efficient, leading to a great burden of protein in the liver and increased liver injury.
 - Autophagy degradation has also been proposed as an important route for degradation of the AAT mutant Z polymers.
- Panniculitis involves inflammation of the fat underneath the skin, causing hardening in lumps and patches, likely due to the unrestrained, destructive action of neutrophil elastase.

ETIOLOGY

Mutations in the SERPINA1 gene result in lung disease through unopposed protease activity and in liver disease by intracellular retention of mutant AAT.

DIAGNOSIS

HISTORY

- Highly variable presentation in neonates and young children
- Most infants develop cholestatic jaundice, hepatosplenomegaly, poor feeding, and poor weight gain.
- Jaundice typically improves around 1 year of age and can then lead to either a continuation of liver disease, progression to cirrhosis, or normal liver function.

- Older children can present as asymptomatic chronic hepatitis, poor feeding, failure to thrive, hepatosplenomegaly, or complications of portal hypertension and cirrhosis.
- Risk of hepatocellular carcinoma in AAT may be independent of cirrhosis.
- Fulminant hepatic failure is rare but has been reported.

PHYSICAL EXAM

There may be signs of jaundice, hepatosplenomegaly, abdominal distention, and other stigmata of chronic liver disease.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Elevated total and conjugated bilirubin, elevated serum transaminases, hypoalbuminemia, or coagulopathy
- Gold standard assessment is protein electrophoresis to determine the protease inhibitor (Pi) phenotype.
- Serum levels of AAT can be helpful to guide workup before phenotype results are available.
- Quantitative serum AAT levels
 - PiMM: 80–200 mg/dL
 - PiZZ: ≤ 20 –45 mg/dL
 - Pi null/null phenotype: 0 mg/dL
 - As an acute-phase reactant, AAT levels can be falsely negative, as they may rise into the normal range in an ill patient.

Imaging

Abdominal ultrasound with Doppler can be useful to assess for portal hypertension and/or for pre-transplantation evaluation in the setting of end-stage liver disease.

Diagnostic Procedures/Other

Diagnosis is determined by identification of the AAT phenotype by serum protein electrophoresis. Liver biopsy is not required for diagnosis but can help to support it.

Pathologic Findings

- Liver biopsy findings can be variable in infants and may include giant

cell transformation, lobular hepatitis, steatosis, fibrosis, hepatocellular necrosis, bile duct paucity, or bile duct proliferation.

- Globular eosinophilic inclusions in some hepatocytes can be seen under H&E stain, which represent dilated ER membranes with polymerized mutant protein.
- Staining with periodic acid–Schiff (PAS) followed by digestion with diastase to stain glycoproteins can be performed to highlight these globules.
- These findings are sometimes seen in other liver diseases, are not visible in all hepatocytes, and may even be absent in neonates.

DIFFERENTIAL DIAGNOSIS

- The differential diagnosis varies with age at presentation.
- Infants generally present with jaundice; the differential diagnosis in infants should include biliary atresia, anatomic biliary abnormalities, congenital infections, galactosemia, and tyrosinemia. (See “[Neonatal Cholestasis](#)” and “[Jaundice](#)” for complete listing.)
- In older children, viral (hepatitis viruses, EBV, and CMV), toxic (ethanol, acetaminophen), metabolic (Wilson disease), and obstructive causes should be considered.

TREATMENT

- There is no specific treatment for the liver disease associated with AAT deficiency.
- Management involves supportive care to try to prevent complications of chronic liver disease.
- Patients with advanced liver disease should avoid alcohol and other hepatotoxins.
- Liver transplantation can be considered for end-stage liver disease. When transplanted, the graft will secrete normal AAT and stop further progression of lung disease.
- Due to increased risk of hepatocellular carcinoma, surveillance imaging and/or α -fetoprotein levels should be considered.
- Patients should be cautioned to avoid smoking, secondhand smoking,

and other agents of inhalation injury.

- Although enzyme replacement therapy can be used in adults to prevent progression of lung disease, it has no effect on liver disease.
- Vaccination against hepatitis A and B

MEDICATION

- Ursodeoxycholic acid, a choleretic agent, can be used to manage cholestasis and pruritus in patients with liver disease.
- Augmentation therapy
 - Pooled human plasma–derived AAT (alpha-1 antiprotease) is the most efficient way to increase the circulating levels of AAT in the plasma and lung.
 - Therapy has been reported to decrease the rate of decline in 1-second forced expiratory volume (FEV₁) and mortality rate during the period of study

SURGERY/OTHER PROCEDURES

- There is no primary therapeutic surgical intervention for AAT deficiency aside from liver transplantation.
- Surgery in patients with native livers can be used to treat complications of portal hypertension.
- Orthotopic liver transplantation should be considered in patients with end-stage liver disease.
- Following transplantation, serum phenotype and AAT level return to donor levels. Lung damage will not progress but is unlikely to be reversed after liver transplantation.
- For lung disease, volume reduction surgery or lung transplantation may be considered.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Annual liver and pulmonary function testing
- Surveillance for hepatocellular carcinoma in Pi ZZ patients is suggested, but consensus on frequency and methodology is lacking.

PROGNOSIS

Approximately 10% of PiZZ and PiSZ individuals will have clinically significant liver disease during childhood; ~50% of the remaining individuals will have mildly elevated aminotransferases. Further significant liver disease may develop later in life.

COMPLICATIONS

- Patients with liver disease may develop complications of chronic liver disease including portal hypertension, cirrhosis, and/or hepatocellular carcinoma.
- Lung disease may progress to early-onset lower lobe emphysema.

CODES

ICD10

E88.01 Alpha-1-antitrypsin deficiency

FAQ

- Q: Do all patients with presumed AAT require liver biopsy for diagnosis?
- A: No. A liver biopsy is not required for diagnosis but may help be performed to support it.
- Q: Are PAS-positive, diastase-resistant globules on liver biopsy diagnostic for AAT deficiency?
- A: No. Diagnosis is made by identification of the AAT phenotype by serum protein electrophoresis. Evidence of these globules on liver biopsy can support the diagnosis but may be absent in PiZZ neonates.
- Q: Will liver transplantation for AAT deficiency have any effect on the lungs?
- A: Yes. When a patient with AAT deficiency gets an orthotopic liver transplant, serum levels of AAT usually return to normal. This halts further progression of lung disease but does not reverse lung damage, which has already occurred.

ALTITUDE ILLNESS

Michael Yaron

BASICS

DESCRIPTION

High-altitude illness represents a spectrum of clinical entities with neurologic and pulmonary manifestations that overlap presentations and share elements of pathophysiology. Acute mountain sickness (AMS) is the relatively benign and self-limited presentation, whereas high-altitude pulmonary edema (HAPE) and high-altitude cerebral edema (HACE) represent the potentially life-threatening manifestations.

EPIDEMIOLOGY

- Altitude illness common with rapid ascent to moderate altitude (8,000–11,500 feet); most serious cases occur at very high altitude (11,500–18,000 feet).
- Children risk developing altitude illness when travelling to high locations with their families.

Incidence

- Children have the same incidence of altitude illness as adults.
- The rapid ascent profile associated with air travel to high-altitude locations results in higher AMS rates. Among skiers who fly or drive to resorts in the western United States, the frequency is approximately 25%.
- HACE is extremely rare in children primarily occurring after prolonged stays at very high altitudes; a place most children should not be.
- HAPE frequency is 1–2% with primary ascent, but reentry HAPE may occur in 6–17% of children who are permanent altitude residents.

RISK FACTORS

- Incidence depends on rate of ascent, sleeping altitude, and previous altitude exposure.
- Individual (genetic) susceptibility plays a key role in risk assessment. Most children with a previous history of AMS or HAPE are likely to

experience similar symptoms with similar ascent profiles.

- Underlying medical conditions resulting in hypoxia sensitivity or pulmonary hypertension: incomplete postnatal circulatory transition, viral respiratory infection, atrial or ventricular septal defects, PFO, PDA, pulmonary vein stenosis, congenital absence of pulmonary artery, obstructive sleep apnea, Down syndrome, hypoplastic lung, and sickle cell disease

GENERAL PREVENTION

- Assess risk factors and plan rate of ascent:
 - Slow ascent is the best prevention strategy; sleeping altitude: ideally first night no higher than 9,200 feet, then 2–3 nights at 8,200–9,800 feet, with subsequent increases limited to 1,500 feet each night and 1 extra day without ascent for every 3,000 feet gained
- Formulation of emergency communication and evacuation plan
 - Difficult descent situations (i.e., further ascent needed before descent possible) should be avoided.
 - Cell or satellite communication may fail.
- Prompt recognition of symptoms
 - Train parents in symptom recognition and treatment principles.

PATHOPHYSIOLOGY

- AMS/HACE: rising intracranial volume and pressure with ascent ultimately resulting in vasogenic edema (HACE). A “tight-fitting” CNS within the skull and spine has less ability to buffer edema and may be more susceptible.
- HAPE: elevated pulmonary artery pressure, uneven vasoconstriction, pulmonary overperfusion injury and leakage, inflammation, and impaired alveolar fluid clearance

DIAGNOSIS

HISTORY

Previous altitude illness suggests similar symptoms in future with similar ascent profiles, rapid rate of ascent to high sleeping altitudes; increased exertion, preexisting medical conditions with hypoxia sensitivity or

pulmonary hypertension, use of prophylaxis medication or respiratory depressants.

- Acute mountain sickness (AMS):
 - All symptoms may range from mild to severe and incapacitating. The diagnosis requires recent altitude gain, a headache, and at least one of the following: anorexia, nausea or vomiting, general weakness or fatigue, dizziness or light-headedness, or difficulty sleeping. These symptoms comprise the adult criteria for AMS and may be used in older children who are able to verbally express headache or hunger. Headache can be assessed by asking if the “head hurts” and GI symptoms by asking the child if they are “hungry” rather than evaluating appetite. Sleep disturbance is common in all visitors to high altitudes but is exacerbated in the setting of AMS.
 - Among infants and older preverbal children (up to 3 years of age), AMS is diagnosed using nonverbal criteria. AMS is manifested by increased fussiness (headache equivalent), decreased playfulness, decreased appetite, and sleep disturbance. In most cases, all of these symptoms are present. Fussiness is a state of irritability that is not easily explained by a cause, such as tiredness, wet diaper, hunger, teething, or pain from an injury. Fussy behavior includes crying, restlessness, or muscular tension. Decreased playfulness may be profound, vomiting may occur, and sleep disturbance is most often manifest as decreased sleep and the inability to nap.
 - Parents can learn to recognize AMS in preverbal children using the Children’s Lake Louise Score.
 - To calculate score, combine the fussiness score with the symptom score.
 - Children’s LLS score ≥ 7 with fussiness score ≥ 4 + symptom score ≥ 3 is considered diagnostic of AMS.

Fussiness score	0	1	2	3	4	5	6
Amount	None		Intermittent		Constant		
Intensity	Not fussy		Moderately fussy		Extremely fussy		

Symptom score	0	1	2	3
Eating	Norm	Slightly less	Much less	Not eating; vomiting
Playing	Norm	Slightly less	Much less	Not playing
Sleeping	Norm	Slightly less or more	Much less or more	Not able to sleep

- Symptoms develop within a few hours after ascent and generally reach maximum severity between 24 and 48 hours, followed by gradual resolution over 1–3 days. The vague nature of AMS presentation has resulted misdiagnoses and morbidity. These symptoms warrant a presumptive diagnosis of AMS and limitation of further ascent, until proven otherwise.
- High-altitude cerebral edema (HACE):
 - Rare in children but rapidly fatal if unrecognized. Develops 2–4 days after ascent.
 - Differentiated from AMS by the presence of neurologic signs. Most common are ataxia, and altered mental status including confusion, progressive unresponsiveness, and coma. Less common are focal cranial nerve palsies, motor and sensory deficits, and seizures.
- High-altitude pulmonary edema (HAPE):
 - Develops over 24–96 hours and may be associated with concurrent viral illness.
 - Although all children have dyspnea on exertion at altitude, dyspnea at rest is an early indicator of HAPE. AMS precedes HAPE development in approximately 1/2 of cases. General malaise progresses to a more specific signs of dyspnea at rest, then cardiopulmonary distress.
 - Young children may show agitation and general debility. Older children may complain of headache, and all ages frequently experience nausea and vomiting. Cough is common.
 - Dyspnea at rest, orthopnea, cyanosis, chest pain, and tachycardia, herald worsening compromise leading within hours to production of pink-tinged sputum, increasing hypoxia with eventual coma, and death.

PHYSICAL EXAM

- There are no diagnostic physical signs in cases of mild AMS. Any evidence of CNS dysfunction, such as mild ataxia or altered mentation is early evidence of HACE.
- Similarly, although dyspnea on exertion is universal at high altitudes, dyspnea at rest is an early indicator of HAPE.
- HAPE exam findings are often less severe than a patient's chest radiograph and the hypoxemia on pulse oximetry would predict. Children appear pale, with or without visible cyanosis. Low-grade fever ($<38.5^{\circ}\text{C}$) and tachypnea are common. Auscultation reveals rales, usually greater in the right lung.

DIAGNOSTIC TESTS & INTERPRETATION

- ECG: HAPE: may reveal RV strain
- Pulse oximetry: HAPE: Arterial oxygen desaturation is a consistent finding, with saturations frequently less than 75%.

Lab

Evaluate arterial blood gas, carbon monoxide level, and CBC (often reveals a leukocytosis with a left shift of the granulocyte series).

Imaging

- Chest x-ray
 - Pulmonary edema pattern variable, from patchy/peripheral to homogeneous in severe cases. Right lung shows more radiographic changes of edema than left. Peribronchial and perivascular cuffing and enlargement of pulmonary artery are common.
- Pulmonary ultrasonography
 - Comet tail microreflection artifacts within interlobular septae thickened by interstitial/alveolar edema
- Brain CT/MR imaging
 - CT imaging consistent with edema and increased intracranial pressure. MRI: high T2 signal in the white matter, specifically in the splenium of the corpus callosum, with diffusion-weighted technique

DIFFERENTIAL DIAGNOSIS

Differential of HAPE includes pneumonia, bronchitis/bronchiolitis, asthma, other pulmonary edema, and pulmonary embolism. HAPE is most

frequently misdiagnosed as pneumonia. With AMS, a differential of viral illness, sepsis, alcohol/drug intoxication, hypothermia, carbon monoxide poisoning, and dehydration should be considered.

TREATMENT

MEDICATION

- Oxygen relieves AMS symptoms (1–2 L/min), easily available in most resorts, reserved for severe cases in remote settings. Hyperbaric therapy also effective, as it simulates descent
- Acetazolamide (carbonic anhydrase inhibitor)
 - Prevention of AMS: 2.5 mg/kg PO q12h, max 125 mg/dose; not routinely used in children. Indicated with unavoidable rapid ascent profile or previous history with similar ascent planned
 - AMS treatment: 2.5 mg/kg PO q8–12h, max 250 mg/dose; **caution if patient has a sulfa allergy**.
 - Paresthesia and taste alterations common
- Dexamethasone (steroid)
 - Prevention of AMS: risk of adverse effects; use not warranted, use slow ascent or acetazolamide.
 - AMS/HACE treatment: 0.15 mg/kg PO/IM/IV q6h, max 4 mg/dose. Oxygen/descent are treatment of choice for severe AMS; if patient has a sulfa allergy, dexamethasone may be used; oxygen, descent, and dexamethasone for HACE
- Nifedipine (calcium channel blocker)
 - Prevention and treatment of HAPE: small children: immediate-release 0.5 mg/kg/dose q4–8h, max 20 mg/dose. If >60 kg, 30 mg sustained-release (SR) PO q12h or 20 mg SR PO q8h. Indicated for treatment in emergency setting where oxygen and descent are not an option. (Oxygen alone provides maximal treatment, no advantage adding nifedipine) May cause hypotension
- Sildenafil (phosphodiesterase inhibitor)
 - Prevention/treatment of HAPE: 0.5 mg/kg/dose PO q8h, max 50 mg/dose q8h. For treatment, only indicated in emergency setting where oxygen and descent are not an option, if nifedipine not well-

tolerated, this medication is an alternative. (FDA warns against use in children.)

General Measures

- Descent (of 1,600–3,300 feet) from altitude of illness onset is effective treatment for all forms of altitude illness.
- Mild AMS
 - Usually self-limited not requiring treatment. Stop ascent and rest until symptoms improve.
 - May be treated without descent if monitoring by reliable caregiver available.
- Moderate to severe AMS
 - Symptomatic treatment with analgesics and antiemetics: ibuprofen, acetaminophen, ondansetron; oxygen if available, give acetazolamide; descend if persistent or severe.
- HACE
 - Descend immediately.
 - Supplemental oxygen to keep $\text{SpO}_2 > 90\%$, bed rest, dexamethasone, portable hyperbaric chamber while awaiting descent
- HAPE
 - Without medical expertise, descend immediately. Otherwise, if mild may treat by stopping ascent, rest, and oxygen to keep $\text{SpO}_2 > 90\%$. Use nifedipine in severe cases if descent is delayed or oxygen unavailable.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Refer to primary care physician for education of prevention strategies and consideration of prophylaxis with future ascent. History of HAPE or severe hypoxemia warrants cardiopulmonary evaluation including echocardiography.

PROGNOSIS

- Excellent if recognized quickly, ascent stopped, and descent and/or therapy initiated

- Can be poor if symptoms go unrecognized or noted without appropriate descent and therapy

FAQ

- Q: Can one develop AMS at moderate altitudes, such as during a ski vacation?
- A: Yes. 25% of visitors from sea level will get AMS symptoms, although the altitudes encountered rarely lead to the development of severe symptoms.
- Q: When can we bring our newborn baby to our mountain house at 9,000 feet?
- A: The postnatal cardiopulmonary transition is nearly complete by 6 weeks and then most babies can safely ascend to moderate altitudes.
- Q: Should I give prophylaxis to my child to prevent AMS?
- A: Not usually. Only children with a significant history of AMS or

unavoidable rapid ascent should be given prophylaxis.

- Q: Is it safe to take my child on a 3-week trek crossing several mountain passes in Nepal?
- A: Not necessarily. Balance the benefits against the risks of being in a remote environment with exposure to environmental dangers (altitude, weather, infectious disease), without easy medical care, evacuation, or communication.

AMBIGUOUS GENITALIA

Sarah Z. Hatab • J. Nina Ham

BASICS

DESCRIPTION

- Genitalia can be defined as ambiguous when it is not possible to categorize the gender of the child based on outward genital appearance.
- Ambiguous genitalia result from various disorders of sexual development (DSD), a generic term defined as a congenital condition in which development of chromosomal, gonadal, or phenotypic sex is atypical.
 - General DSD categories are sex chromosome DSD; 46,XX DSD; 46,XY DSD; ovotesticular DSD; 46,XX testicular DSD; and 46,XY complete gonadal dysgenesis.
 - Specific diagnoses (when available) are preferable to these broad categories.
 - Previous terms such as “intersex,” “pseudohermaphroditism,” or “sex reversal” should be avoided.
- Criteria that suggest DSD include the following:
 - Bilateral nonpalpable testes
 - Micropenis (stretched length <2.5 cm)
 - Perineal hypospadias or mild hypospadias with a unilateral undescended testis
 - Clitoromegaly (width >6 mm or length >9 mm), posterior labial fusion
 - An inguinal/labial mass
 - Family history of a DSD
 - Discordance between genital appearance and prenatal karyotype
- DSDs also comprise sex chromosome disorders including Turner (45,X) and Klinefelter syndromes (47,XXY), which usually do not present as ambiguous genitalia.

EPIDEMIOLOGY

- Genital anomalies at birth may have a prevalence as high as 1 in 300.
- External genitalia ambiguity has a prevalence of approximately 1 in 5,000 births.
- Congenital adrenal hyperplasia (CAH) is the most common cause of DSD (classified as a 46,XX DSD) and is discussed in detail in a separate chapter.
- Partial androgen insensitivity syndrome (PAIS) is the next most common cause of DSD (classified as a 46,XY DSD).
- Disorders causing sexual ambiguity are congenital and usually present in the newborn period.
- Later presentations in older children and young adults can occur.
Examples:
 - 46,XY individuals with complete 17 α -hydroxylase/17,20-lyase deficiency may present in adolescence with hypertension and delayed puberty.
 - Women with complete androgen insensitivity syndrome (CAIS) may present during adolescence with primary amenorrhea.
 - Children with 5 α -reductase deficiency may become virilized during puberty.

GENETICS

- Several single-gene disorders causing gonadal dysgenesis have been described. However, only 15–20% of patients with DSDs are diagnosed at the molecular level.
- 46,XY DSD may be associated with mutations in the following genes:
 - Genes involved in testicular development: sex-determining region on Y (SRY), SOX9, steroidogenic factor 1 (SF-1), Wilms tumor suppressor gene (WT1), WNT4 duplication, and DAX1 duplication.
 - Genes involved in steroid hormone action or synthesis (autosomal recessive, except for the androgen receptor)
 - LH/choriogonadotropin receptor (LHCGR) gene leading to Leydig cell hypoplasia and decreased testosterone
 - Genes encoding adrenal steroidogenic enzymes: 17 α -hydroxylase (CYP17A1), 3 β -hydroxysteroid dehydrogenase, (HSD3B2), P450 oxidoreductase, and StAR protein (lipoid hyperplasia)
 - Gene encoding 5 α -reductase (SRD5A2), leading to defective

conversion of testosterone (T) to dihydrotestosterone (DHT).

DHT is necessary for the development of male external genitalia in utero.

- ▢ Androgen receptor (AR) gene located on the X chromosome (X-linked recessive), leading to impaired androgen action
- 46,XX DSD may be associated with mutations in the following genes:
 - Genes involved in ovarian development and leading to gonadal dysgenesis: FSH receptor (FSHR), SF-1
 - Genes involved in testicular development: presence of SRY, SOX9 duplication
 - Genes encoding steroidogenic enzymes, involved in cortisol biosynthesis, leading to virilizing CAH: 21-hydroxylase (CYP21A), the most common form; 11 β -hydroxylase (CYP11B1); 3 β -hydroxysteroid dehydrogenase (HSD3B2)
 - Aromatase gene (CYP19A1), leading to impaired placental conversion of fetal adrenal androgens to estrogens
- Sex chromosome DSD (45,X; 47,XXY; 45,X/46,XY; and 46,XX/46,XY) are caused by meiotic or mitotic nondisjunction.

PATHOPHYSIOLOGY

- 46,XX DSD
 - Masculinization of the female fetus is caused by androgens produced by the fetus or transferred across the placenta. The most common cause is CAH in which the fetal adrenal glands overproduce androgens in an attempt to correct cortisol deficiency.
 - The ovaries and müllerian derivatives are normal, and the sexual ambiguity is limited to masculinization of the external genitalia.
- 46,XY DSD
 - Incomplete masculinization of the male fetus can be caused by enzyme disorders of testosterone synthesis (e.g., CAH, 5 α -reductase deficiency), unresponsiveness to testosterone action (androgen insensitivity syndromes), or defects in testicular development (complete or partial gonadal dysgenesis).
- Ovotesticular DSD
 - Includes patients with both ovarian and testicular elements. Combinations include one ovary and one testis, two ovotestes, or

one ovotestis with either an ovary or a testis. Often, differentiation of internal and external genitalia coincides with the gonad on the ipsilateral side.

- Karyotypes are 46,XX most commonly; the molecular basis of this disorder may not be known; 46,XX/46,XY and 46,XX/47,XXY reported.
- Gonadal dysgenesis
 - Mixed gonadal dysgenesis (classically 45,X/46,XY) involves a streak gonad on one side and a testis, often dysgenetic, on the other side. The clinical phenotype is highly variable and ranges from female external genitalia through all stages of ambiguous genitalia to a normal male.
 - Pure (complete) gonadal dysgenesis (46,XX, 46,XY, or a Turner syndrome karyotype) involves replacement of gonads by streak gonads. Neonates look female at birth and often present later in life with delayed puberty and primary amenorrhea.

DIAGNOSIS

- Ambiguous genitalia in the neonate should be treated as an emergency, and diagnostic evaluation undertaken as soon as possible.
- CAH, the most common cause of DSD, can be life threatening when accompanied by salt wasting. Also, DSD is disturbing for families and calls for immediate investigation, counseling, and support.

HISTORY

Obtain a careful pregnancy and family history addressing the following:

- Drug ingestions
- Teratogen exposures
- Infections during the pregnancy
- Androgenic changes in the mother
- Family history suggestive of CAH or androgen insensitivity
- History of consanguinity

PHYSICAL EXAM

Notable features include phallic size, symmetry of external genitalia,

presence and location of palpable gonads, and presence of additional anomalies.

- Palpable gonads: imply the presence of Y-chromosome material
- Labial fusion: measurement of the anogenital ratio (distance from anus to posterior fourchette divided by distance from anus to base of phallus). If >0.5 , this suggests virilization with posterior labial fusion.
- Presence of a vagina
- Position of the urethra
- Length and diameter of penis/clitoris: stretched penile length at term usually ≥ 2.5 cm; clitoral length is usually ≤ 1 cm.
- Development of the scrotum
- Asymmetry of external genitalia: suggests ovotesticular or 45,X/46,XY DSDs
- Other dysmorphic features
- Hypertension is seen with 17 α -hydroxylase and 11-hydroxylase deficiencies.
- Features of the classic disorders of adrenal steroidogenesis

DIAGNOSTIC TESTS & INTERPRETATION

Lab

Initial evaluation should be targeted to help with sex assignment and assessment of gonadal and adrenal steroids. A 1st-line investigation includes the following:

- Karyotype, or fluorescence in situ hybridization (FISH) (X- and Y-specific probes)
- Measurement of 17 α -hydroxyprogesterone (17-OHP), testosterone, anti-müllerian hormone (AMH) (reliable indicator of testicular tissue), and serum electrolytes

Second-line investigations depend on the karyotype, the presence of palpable gonads, and the 17-OHP levels. These can be ordered after the 1st-line tests or ordered simultaneously, depending on the clinical situation.

- Karyotype is 46,XX and nonpalpable gonads:
 - Most commonly due to CAH
- Karyotype is 47,XY: Investigations include tests to determine if testes are present and capable of producing normal levels of androgens:

- LH, FSH, müllerian-inhibiting substance (MIS), T, and DHT
- hCG stimulation test will help differentiate disorders of abnormal response to androgen from disorders of androgen synthesis.

Imaging

- Ultrasonography of the abdomen and pelvis
 - Part of the 1st-line investigation
 - Can help determine the presence of gonads, uterus, and/or vagina
 - Only 50% accurate in showing intraabdominal testes
- Retrograde urethrogram can help evaluate the urogenital sinus.
- MRI can further delineate the internal anatomy.

Diagnostic Procedures/Other

- Cystoscopy/vaginoscopy is gold standard method to assess the urethral and vaginal anatomy.
- Laparoscopy +/- gonadal biopsy may be required for definitive evaluation of the reproductive structures.

DIFFERENTIAL DIAGNOSIS

- Gonadal dysgenesis
- Ovotesticular DSD
- 46,XX DSD
 - CAH causing virilization in female
 - Maternal androgen exposure
 - Exogenous androgens or endogenous production (e.g., maternal virilizing tumor)
- 46,XY DSD
 - CAH causing undervirilization of boys
 - 5 α -Reductase deficiency prevents in utero formation of male external genitalia.
 - Syndromes of androgen resistance due to abnormalities in androgen receptor or postreceptor defects.
- Multiple congenital anomalies: Ambiguous genitalia can be a part of a spectrum of congenital anomalies involving the rectum and urologic system.
- Idiopathic

TREATMENT

- Counsel family to not make announcements describing gender until gender assignment is determined.
- Medical staff should use terms such as “your child” or “the baby” rather than “he” or “she.”
- Parents should be counseled that the diagnostic information as well as surgical factors, prediction of hormone function, and potential for fertility will be taken together as a whole.
- Gender assignment should be made through a multidisciplinary team approach with consultations from endocrinology, urology, neonatology, genetics, psychiatry/psychology, and social work. If these services are not available, the child and family may benefit from transfer to a pediatric tertiary care facility that can provide this multidisciplinary approach.

MEDICATION

- With the exception of CAH, most DSD conditions do not require specific medical treatment until puberty.
- At the time of expected puberty, hormonal therapy is usually started in patients with hypogonadism: between 10.5 and 12 years for females and 12.5 and 14 years for males.

ADDITIONAL TREATMENT

General Measures

- Surgical management
 - If the gender assignment is female, delaying clitoral surgery should be considered given the potential risk for disturbance of sensation. Vaginoplasty may be acceptable in infancy given the potential for improved functional outcome.
 - If gender assignment is male, phallic reconstruction can be done when the team and parents are comfortable with the timing. Urethral reconstruction for hypospadias is usually scheduled between 6 and 24 months of age.
 - Gonadectomy or repositioning may be recommended in patients at risk of gonadal malignancy (gonads bearing the Y chromosome).

Tumor risk is heterogeneous among DSDs (e.g., high in mixed gonadal dysgenesis [MGD] and low in AR), and the optimal age and type of surgery can vary substantially.

- Psychosocial management
 - Long-term counseling for the child and parents by mental health staff with expertise in DSDs is critical to promote psychosocial adaption at all stages of cognitive and psychological development.
 - The team can facilitate decision-making processes involving gender assignment/reassignment, timing of surgery, and hormonal replacement.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Long-term follow-up may involve monitoring hormone levels, linear growth, and sexual and psychological development.
- Follow-up also involves monitoring for gonadal malignancy. Surveillance imaging and testicular palpation should be performed in all DSD patients with abdominal or scrotal testes respectively.

PROGNOSIS

The cosmetic outcome from surgery is usually good. The potential for age-appropriate sexual function is usually good with therapy. The potential for reproductive function depends on the diagnosis. Long-term studies of psychological adjustment are underway.

CODES

ICD10

- Q56.4 Indeterminate sex, unspecified
- E25.0 Congenital adrenogenital disorders assoc w enzyme deficiency
- Q56.3 Pseudohermaphroditism, unspecified

FAQ

- Q: Should a child's sex assignment be consistent with the karyotype?
- A: This is a major decision that should involve the family and the treatment team. Future potential for sexual, hormonal, and reproductive function, in addition to genetics, are all important factors.
- Q: What clues can the physical exam give to the timing of in utero events causing sexual ambiguity?
- A: In the virilized female, labioscrotal fusion results from androgen exposure prior to 12 weeks' gestation. Thereafter, androgen exposure can cause only clitoromegaly.

AMBLYOPIA

Melissa A. Simon • Michael F. Chiang

BASICS

DESCRIPTION

Amblyopia is a decrease in best corrected visual acuity in an otherwise anatomically normal eye. It is generally classified by cause, with 3 primary types:

- Refractive amblyopia: resulting from uncorrected refractive error (improper focusing of light by the eye which generally requires correction by eyeglasses or contact lenses), with the following subtypes:
 - Anisometropic amblyopia: resulting from asymmetric refractive error and resultant unilateral blurring. This condition is the most common cause of refractive amblyopia. One specific example is meridional amblyopia, which results from large uncorrected astigmatism in one or both eyes.
 - Ametropic amblyopia: resulting from significant refractive error in both eyes
- Strabismic amblyopia: resulting from strabismus (misalignment of the eyes) and subsequent lack of an image that can be “fused” or integrated into a single image in the brain. This condition is most likely with early-onset, constant strabismus. Approximately 50% of patients with strabismus will also have amblyopia.
- Deprivation amblyopia: resulting from optical or anatomic pathology (e.g., cataract, ptosis, corneal opacity, prolonged patching), which prevents the formation of a clear image in one or both eyes.
Deprivation, especially if it begins early in life, is associated with the most severe amblyopia.

EPIDEMIOLOGY

Amblyopia is the most common cause of unilateral vision loss in children and young adults.

Prevalence

Large population-based studies indicate that 0.8–3.3% of the adult population has amblyopia.

PATHOPHYSIOLOGY

- Asymmetric input between the 2 eyes (e.g., unilateral cataract, anisometropia, etc.) is more likely to cause amblyopia than symmetrically poor images due to competitive influences between the 2 eyes. As a result, amblyopia is usually unilateral.
- Bilateral amblyopia may result from severe, symmetric bilateral image degradation such as bilateral cataract, bilateral high ametropia (high refractive error), etc.
- Visual acuity in amblyopic eyes varies from minimal impairment (20/25) to legal blindness (<20/200) or worse. Other significant impairments in amblyopic eyes may include reduced contrast sensitivity, reduced or absent binocularity and depth perception, and impaired or distorted spatial perception. Peripheral visual fields are preserved, and vision is never completely lost (no light perception) from amblyopia alone.

DIAGNOSIS

SIGNS & SYMPTOMS

Poor vision

HISTORY

- Age of onset of vision loss
- Eye trauma, injury, or surgery
- Refractive error or glasses
- Ptosis or ocular occlusion (because amblyopia related to ptosis is often due to resultant astigmatism, this can occur even if the affected eye is not completely occluded)
- Family history of strabismus, anisometropia, or amblyopia
- History of prematurity or developmental delay

PHYSICAL EXAM

- Visual acuity is the single most significant sign in detection of amblyopia. Vision must be tested in each eye separately with reliable occlusion (ideally an adhesive patch). Because most amblyopia is monocular, testing vision with both eyes open is inadequate as a screening tool.
- Binocularity tests such as Titmus stereopsis (3D fly) will detect suppression, which is frequently associated with amblyopia.

DIAGNOSTIC TESTS & INTERPRETATION

- Vision testing in young children is difficult and, sometimes, unreliable.
- Children must be tested with each eye separately.
- Repeating the tests and adjunctive tests including the Titmus test, cover testing, photoscreening, and Brückner red reflex test will increase the sensitivity of screening.

Imaging

Imaging studies of the optic nerves and posterior visual pathways may be useful in selected cases to exclude other causes of vision loss.

DIFFERENTIAL DIAGNOSIS

- Amblyopia is diagnosed by exclusion: Conditions that cause vision loss without easily recognized pathology might be mistaken for amblyopia.
- In children, the differential diagnosis of vision loss in eyes that appear normal by penlight includes the following:
 - Uncorrected refractive error (hyperopia, myopia, astigmatism)
 - Optic nerve hypoplasia
 - Optic atrophy
 - Compressive, toxic, or hereditary optic neuropathies
 - Retinopathies, including Leber congenital amaurosis, Stargardt disease, retinitis pigmentosa, and others
 - Central visual impairment (cortical blindness)
 - Glaucoma
 - Factitious or functional causes (hysterical blindness)

TREATMENT

GENERAL MEASURES

- Refractive correction, when needed, is critical and can improve amblyopia before additional treatment.
- Unilateral amblyopia
 - Treat underlying cause of vision loss (strabismus, anisometropia, optical opacity) and force preferential use of the amblyopic eye.
 - The classic and most common treatment is occlusion with an adhesive patch worn over the opposite (unaffected) eye for hours daily.
 - The amount of time of occlusion necessary to reverse amblyopia depends on variables including the severity of amblyopia, cause of amblyopia, age, and other associated ocular conditions. Research studies have not identified an optimal time of occlusion.
 - Typical duration of treatment is from a few weeks to months but can be longer in some cases.
 - Infants and very young children require closer observation to prevent reversing the amblyopia to the previously preferred eye (occlusion amblyopia) from excessive patching.
 - Optical penalization of the opposite (unaffected) eye using topical cycloplegic eyedrops, such as atropine 1%. Recent studies suggest that atropine penalization may be as effective as patching to treat mild or moderate amblyopia.
 - Treatment should be attempted in amblyopic children within the “sensitive period” of birth to 8 years of age. Successful outcomes are far more likely when treatment is initiated early. However, recent research suggests that treatment can still be effective in teenagers, especially those who have not been previously treated. Treatment is usually continued until visual acuity is equal to the opposite eye or no further improvement is seen over several examinations with treatment.
 - The primary risk of treatment is overcorrection, with iatrogenic amblyopia in the occluded opposite eye.
- In strabismic amblyopia, initiation of treatment for amblyopia need not wait for correction of the strabismus. Moreover, the stability of the surgical strabismus correction is improved if amblyopia therapy is

initiated before surgery.

- Treatment is usually continued until visual acuity in both eyes is equal or until vision in the amblyopic eye shows no further improvement after several examinations over a period of time.

ISSUES FOR REFERRAL

Prompt referral of failures and children suspected of poor vision for complete ophthalmic examination is essential for successful amblyopia screening programs.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- In general, the younger the patient, the more intensive the patching therapy, and the milder the amblyopia, the more frequent vision testing is necessary to ensure that vision in the opposite, occluded eye is not harmed.
- Children are clever at finding ways to avoid the temporary vision impairment from patching and will peek or remove patches frequently.
- In younger children, amblyopia may recur after successful treatment.

Patient Monitoring

- Children should be retested frequently and retreated if vision drops after finishing successful initial treatment.
- Approximately 1/4 of children treated for amblyopia experience a recurrence in the 1st year after treatment.
- Testing should continue at least annually until the child is at least 8 years old, and recent trials suggest there may be benefit to monitoring through adolescence.

PATIENT EDUCATION

Because the outcome of amblyopia depends entirely on early detection and treatment within the first few years of life, all children should be screened by monocular recognition visual acuity as early as possible, and testing has traditionally been recommended to be repeated annually until 8 years of age (although evidence now suggests potential benefits of screening

through adolescence). The U.S. Preventive Services Task Force recommends screening beginning at age 3 years. Ongoing research is investigating potential benefits of screening children as early as age 1 year. In general, children who are not capable of accurate visual acuity testing by 4 years of age should be referred for complete evaluation.

PROGNOSIS

- After treatment, amblyopia may recur, and vision should be retested regularly.
- Patients with strabismus, even if previously treated with glasses or surgery, must be followed for amblyopia.
- Vision loss from amblyopia will persist even after the condition that originally caused the amblyopia has resolved. In some cases, when there is no obvious cause, a history of episodes of anisometropia, occlusion, or strabismus must be considered.

COMPLICATIONS

- Left untreated, amblyopia results in irreversible, uncorrectable vision loss after visual maturity (8–10 years of age).
- Usually, the vision loss is unilateral, and the functional effects may be minimal if vision in the remaining eye is normal.
- In bilateral cases, or if other diseases or injury affects the remaining eye, the outcome can be significant functional impairment, including legal blindness.

CODES

ICD10

- H53.009 Unspecified amblyopia, unspecified eye
- H53.029 Refractive amblyopia, unspecified eye
- H53.039 Strabismic amblyopia, unspecified eye

FAQ

- Q: My child refuses to wear a patch. Are there alternatives to patching?
- A: Yes. Optical penalization with glasses, atropine cycloplegic penalization, and even contact lens occlusion can be effective. Research shows that patching and atropine can be similarly effective depending on severity of amblyopia and refractive error. Parental support, encouragement, and reward are essential for treatment compliance.
- Q: How long will patching or atropine be necessary?
- A: It is not possible to predict exactly how long treatment will be necessary to restore vision. In general, the younger the patient, the milder the impairment, and the more intensive the patching, the more quickly vision is restored. In general, patching is usually continued for 1–6 months in most cases of anisometropic or strabismic amblyopia. Normalization of vision or lack of further improvement is usually the treatment end point.
- Q: Will vision be normal after treatment?
- A: The degree of recovery with amblyopia therapy depends on the density of the amblyopia, the cause, and the age at which treatment is initiated. In almost all children younger than 6–8 years of age, some visual improvement can be expected with amblyopia treatment, although not all patients will improve to 20/20 vision.

- Q: Will patching eliminate the need for glasses?
- A: No. Patching does not influence the outcome of refractive errors (power of glasses, refractive error). Glasses may still be needed after patching or atropine is completed. In fact, glasses can improve amblyopia before additional treatment is introduced.
- Q: Will treatment for amblyopia improve the strabismus?
- A: No. In most cases, patching for amblyopia will not eliminate strabismus or the need for strabismus surgery. However, in most cases, it is best to begin amblyopia treatment before surgery to improve the surgical outcome.
- Q: Is “vision therapy” without patching an effective treatment for strabismus?
- A: Although eye exercises, pleoptics, and other vision therapies have been used to treat amblyopia, none is as effective as patching or other occlusive therapy. Current vision therapy techniques have not been proven to improve amblyopia.

AMEBIASIS

Jason Y. Kim

BASICS

DESCRIPTION

Clinical syndromes associated with *Entamoeba histolytica* infection

EPIDEMIOLOGY

- Fecal–oral transmission
- Transmission also via contaminated water and food
- The incubation period is typically 1–3 weeks but can range from a few days to months or years.

Incidence

- Amebiasis accounts for 40–50 million cases of colitis worldwide.
- 40,000–110,000 deaths annually

Prevalence

- The estimated prevalence in the United States is 4%, although there have been no recent serosurvey in developed countries.
- Worldwide distribution involving an estimated 10% or more of the world's population
 - Most common in tropical areas, with infection rates as high as 20–50%
 - Highest morbidity and mortality are seen in developing countries in Central America, South America, Africa, and Asia.

GENERAL PREVENTION

- Treatment of drinking water
- Hand washing
- Appropriate disposal of human fecal waste
- Use of condoms
- Infection-control measures: Standard precautions are recommended for the hospitalized patient.

RISK FACTORS

- The very young, the elderly, and patients with underlying immunosuppression or malnutrition are at highest risk for severe disease.
- Patients in whom the diagnosis should be considered include the following:
 - Immigrants from or travelers to endemic areas
 - Children with bloody stools or mucus in stools
 - Children with hepatic abscess
 - The febrile child with right upper quadrant pain and tenderness, abdominal pain, or discomfort
 - The child with hepatomegaly, typically without jaundice

PATHOPHYSIOLOGY

- *E. histolytica* is excreted as cysts or trophozoites in the stool of infected patients.
- Ingested cysts are unaffected by gastric acid and become trophozoites that colonize and invade the colon.
 - Amebae attach to epithelial cells via a galactose/N-acetylgalactosamine (Gal/GalNac)–binding lectin.
 - The parasite has the ability to lyse human epithelial cells or kill by inducing apoptosis.
 - Then cytokines and chemokines released attract neutrophils, macrophages, and lymphocytes. The host immune response contributes significantly to the reduction of epithelial integrity.
 - Amebae then use cysteine protease to cleave extracellular matrix proteins to invade the submucosal layers.
 - The EhCPDH112 complex interacts with mucosal tight junction proteins to produce mucosal damage.
- Amebae can then disseminate directly from the intestine to the liver in up to 10% of patients. Dissemination from the liver to the lung, heart, brain, and spleen has been described.

ETIOLOGY

- *E. histolytica* is a nonflagellated protozoan parasite.
- Other species of the *Entamoeba* family are nonpathogenic, including the morphologically identical *Entamoeba dispar*.

DIAGNOSIS

HISTORY

- Intestinal disease may be asymptomatic or have mild symptoms such as abdominal discomfort, flatulence, constipation, and occasionally diarrhea.
- Nondysenteric colitis is characterized by intermittent diarrhea and abdominal pain.
- Acute amebic colitis (dysenteric) is associated with grossly bloody stools with mucus, abdominal pain, and tenesmus.

PHYSICAL EXAM

- Fever may be present
- Abdominal tenderness, abdominal rigidity, and rebound are variably present.
- Right upper quadrant tenderness and jaundice may be present in cases of liver abscess.

DIAGNOSTIC TESTS & INTERPRETATION

The diagnosis of amebiasis depends on the recognition of typical symptoms and routine laboratory tests.

Lab

- CBC typically reveals a leukocytosis.
- Transaminases are often not elevated.
- Occult blood is detected in stool.
- Stool samples
 - Isolation and visualization
 - Serial stool samples, usually 3, are recommended.
 - Samples obtained within 1–2 hours of passage should be examined by wet mount and fixed in formalin and polyvinyl alcohol.
 - Serial stool samples are necessary because cysts may be shed intermittently. 3 serial stool samples will detect up to 70% of patients with amebic colitis and 50% of patients with hepatic abscess.

- Stool samples should not be contaminated by urine, water, barium, enema substances, laxatives, or antibiotics because these substances may destroy or interfere with identification of the trophozoites.
 - Microscopy has a sensitivity of <60% and specificity of 10–50% on a single sample.
- 2nd-generation stool antigen testing kits (commercially available) also have demonstrated excellent sensitivity and specificity comparable to real time PCR.
- Molecular testing to differentiate *E. histolytica* from nonpathogenic *Entamoeba* species is in the research phase.
- Serology
 - Serum antiamebic antibodies are considered an adjunct to diagnosis.
 - ~85% of patients with amebic dysentery and 99% of patients with liver amebiasis will have positive serology.

Imaging

- US, CT, or MRI of the liver may reveal liver abscess.
- In patients with hepatic amebiasis, chest x-ray may reveal elevation of the right hemidiaphragm.

Diagnostic Procedures/Other

- Note: Amebae are difficult to visualize in abscess aspirates, and substantial risk is associated with CT- or US-guided procedures, including bleeding, peritonitis secondary to spillage of amebae, or rupture of echinococcal cysts.
- Colonoscopy

Pathologic Findings

- Identification of trophozoites or cysts in the stool
- Colonic or rectal mucosa visualized by colonoscopy reveals ulcerations, and amebae can often be found around these lesions.

DIFFERENTIAL DIAGNOSIS

The diagnosis is often missed in children because the diagnosis is not considered in the differential. Because it is not common in the United States, amebiasis may initially be misdiagnosed as bacterial dysentery. Differential diagnosis includes the following:

- Infection
 - Salmonella species
 - Shigella species
 - Campylobacter species
 - Yersinia species
 - Clostridium difficile
 - Escherichia coli (enteroinvasive and enterohemorrhagic)
- Pyogenic abscess
- Echinococcal cyst
- Inflammatory bowel disease
 - Crohn disease
 - Ulcerative colitis
- Ischemic colitis
- Diverticulitis
- Arteriovenous malformations
- Hepatoma

TREATMENT

MEDICATION

First Line

- Asymptomatic intestinal amebiasis: intraluminal agents
 - Iodoquinol is the drug of choice. The recommended dosage is 30–40 mg/kg/24 h (max, 1,950 mg) PO in 3 divided doses for 20 days.
- Acute amebic colitis or extraintestinal amebiasis
 - Metronidazole (a tissue-active agent) 35–50 mg/kg/24 h PO in 3 divided doses for 10 days (max, 2,250 mg/24 hr) **plus** a course of treatment with an intraluminal-active agent (as the preceding)
 - ~1/3 of patients treated with metronidazole alone will relapse.

Second Line

- Asymptomatic intestinal amebiasis
 - Diloxanide furoate (Furamide) at doses of 20 mg/kg/24 h (max, 1,500 mg/24 h) PO in 3 divided doses or paromomycin, 25–35 mg/kg/24 h PO in 3 divided doses for 7 days

- Acute amebic colitis or extraintestinal amebiasis
 - 1 study has reported good efficacy using nitazoxanide in children; however, the sample size was small and the analyses combined *E. histolytica* and *E. dispar* into 1 stratum.
 - However, nitazoxanide shows good activity in vitro against *E. histolytica*.

General Measures

- The goal of treatment is the elimination of tissue-invading trophozoites and intestinal cysts.
- The choice of treatment regimens depends on the clinical presentation.
- Agents that are active against *E. histolytica* are divided into 2 categories: drugs with activity against intraluminal amebae and drugs with activity against extraintestinal and invasive amebiasis.

SURGERY/OTHER PROCEDURES

Patients with large liver abscesses or who have failed medical therapy should be considered candidates for surgical or percutaneous drainage.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Follow-up stool examination is always necessary to ensure eradication of intestinal amebae.
- For amebic abscesses, drainage should be considered if response to medical therapy has not occurred in 4–5 days.

PROGNOSIS

Clinical improvement is expected within 72 hours of initiation of therapy.

COMPLICATIONS

- Amebic liver abscess
 - 2nd most common presentation of amebiasis, often not associated with amebic dysentery
- Ameboma
 - Abdominal mass representing granulation tissue in the colon

- Extraintestinal manifestations of amebiasis are presumed to be a result of direct extension from liver abscesses. These include the following:
 - Pericarditis
 - Pleuropulmonary abscess or empyema
 - Bronchohepatic fistula
 - Genitourinary tract abscess
 - Cerebral abscess
 - Cutaneous amebiasis
 - This is a rare finding in children, with ~6,510 cases reported in the literature.
 - Shallow painful cutaneous ulcers in the diaper area, usually found in association with amebic colitis or dysentery.
 - Epidemiologic studies from countries with high prevalence of amebiasis show an association between amebic diarrhea and poor growth. The negative effect on growth was significantly more deleterious than diarrhea caused either by *Giardia* or *Cryptosporidium*.

CODES

ICD10

- A06.9 Amebiasis, unspecified
- A06.0 Acute amebic dysentery
- A06.4 Amebic liver abscess

FAQ

- Q: How often does a liver abscess complicate intestinal amebiasis?
- A: About 10% of children with intestinal amebiasis will develop a liver abscess.
- Q: What is the best diagnostic study for a suspected amebic liver abscess?
- A: Serology is the best way to diagnose amebiasis as the cause of a liver abscess. Stool studies are usually negative at the time that a liver abscess has complicated intestinal amebiasis; thus, the yield of stool studies is low.

AMENORRHEA

Renee K. Kottenhahn • Deborah B. Ehrenthal

BASICS

DESCRIPTION

Amenorrhea is the absence of menstruation. It is divided into 2 categories:

- Primary amenorrhea is the failure to begin menstruation by 16 years of age in girls with otherwise appropriate pubertal development or by age 14 years in the absence of secondary sexual characteristics. This diagnosis should also be considered if a girl has not menstruated within 2 years of obtaining Tanner IV breast development regardless of her age.
- Secondary amenorrhea is the cessation of menstruation for 3 cycles or 6 months in girls and women with previously established regular cycles:
 - Should not be used when referring to girls who are within 2 years of menarche because regular ovulatory cycles have not yet been established; their periods are unpredictable.

A regular menstrual cycle is a sign of good health. The absence of menses or disruption of regular cycles once they have been established can result from systemic disease, genetic or anatomic abnormalities, physical or emotional stress, or unrecognized pregnancy. The goal of the evaluation is to identify the underlying cause.

EPIDEMIOLOGY

There is insufficient information about the incidence of amenorrhea in contemporary pediatric populations.

- Primary amenorrhea
 - Approximately 5% of girls in North America fail to reach menarche by 14.5 years of age.
 - The most common chromosomal abnormality associated with primary amenorrhea is Turner syndrome, occurring in 1 to 2,500 female live births.
- Secondary amenorrhea

- Excluding pregnancy, anovulation is the most common cause of secondary amenorrhea.
- Amenorrhea associated with obesity or polycystic ovary syndrome (PCOS) is becoming a common cause of both primary and secondary amenorrhea among adolescents in developing countries.

GENERAL PREVENTION

- Healthy lifestyle avoiding excess weight gain or weight reduction
- Avoidance of excessive athletic activity or training
- Management of emotional stress
- Adherence with chronic disease management (adequate glycemic control for persons with diabetes) and avoidance of additional physiologic stressors

ETIOLOGY

Menstruation requires the presence of functional female internal genitalia with an intact and patent outflow tract and appropriate stimulation and regulation of the endometrial lining by the hypothalamic–pituitary–ovarian axis. Genetic disorders, anatomic abnormalities, or disruption at any level of the hormonal axis can each lead to amenorrhea.

DIAGNOSIS

GENERAL APPROACH

A stepwise approach to the evaluation, guided by the history and physical exam, is recommended.

- Phase 1: Exclude pregnancy by urine or serum β -hCG testing.
- Phase 2: Obtain a complete menstrual history to differentiate between primary and secondary amenorrhea to help identify the underlying cause.
- Phase 3: Perform a directed physical exam.
- Phase 4: Initiate stepwise diagnostic testing to assess for causes of amenorrhea.

HISTORY

- Age of patient

- Genetic abnormalities should be a consideration in younger patients with primary amenorrhea.
- Premature ovarian failure is a stronger consideration with increasing patient age.
- Past and current medical history
 - Prior/current/chronic illness including autoimmune, renal, thyroid, or liver disease; diabetes; or cancer (radiation or chemotherapy), which may be the underlying cause of amenorrhea
- Stressful life events
 - Stress can lead to amenorrhea but should be considered a diagnosis of exclusion.
- Growth and weight changes
 - Consider endocrinopathy, genetic disease, PCOS, rapid weight gain, eating disorder, or other chronic disease.
- Behavioral
 - Eating disorder and/or excessive exercise
- Headaches
 - Assess for visual field defects, dizziness (suggesting pituitary tumor or other intracranial process)
- Reproductive and menstrual history
 - Age at menarche
 - Menstrual cycle history: regularity, flow, duration; characteristics of last menstrual period (normal or abnormal)
 - Sexual history: sexual activity, prior pregnancy, current or prior contraceptive use (Depo-Provera can cause amenorrhea for up to 18 months)
 - A history of symptoms of pre/perimenstrual molimina (breast tenderness, fluid retention, cramping) suggests prior ovulatory cycles.
 - Risk factors for uterine scarring, such as prior gynecologic surgery
- Galactorrhea
 - Spontaneous milky discharge from the breast suggests elevated prolactin or thyroid abnormality or may be due to manual stimulation, medications, pituitary tumor, or illicit drug use (cannabis, opiates, amphetamines).

- Abdominal or pelvic pain
 - Cyclic or intermittent severe abdominal/pelvic pain suggests a uterine anomaly or obstruction.
- Skin and hair
 - Excess hair growth (inquire about shaving, plucking, or waxing), acne, balding, and acanthosis nigricans are symptoms of androgen excess and suggest PCOS, congenital adrenal hyperplasia (rare), or a tumor (rare).
 - Easy bruising or violaceous striae suggest Cushing syndrome.
- Medications
 - Hormonal medications (e.g., Depo-Provera or hormonal contraceptives), cytotoxic medications, illicit drugs, antidepressant drugs, antipsychotic drugs (e.g., risperidone), and other medications including opiates

PHYSICAL EXAM

- General appearance, height, and weight with calculation of body mass index (BMI, in kg/m^2):
 - Obesity raises suspicion of PCOS or possible Cushing syndrome.
 - Athleticism or underweight suggests female athlete triad or eating disorder, respectively.
 - Stigmata of Turner syndrome (short stature, webbed neck, etc.) or other genetic syndromes
 - Abnormal growth pattern suggests endocrinopathy, dietary restriction, chronic disease, or genetic disorder.
- Skin exam
 - Acne, hirsutism (increased facial hair, midline hair over sternum and lower abdomen), acanthosis nigricans, and balding are suggestive of virilization or PCOS.
 - Bruises or pigmented striae suggest Cushing syndrome.
- Tanner staging and breast exam
 - Abnormal Tanner stage for chronologic age suggests an endocrine, metabolic, or genetic abnormality.
 - Galactorrhea suggests abnormalities in prolactin or thyroid.
- Thyroid nodule or enlargement
 - Evaluate for hyperthyroidism or hypothyroidism.

- Abdominal mass
 - Evaluate for uterine obstruction, tumor
- Genitourinary exam
 - Abnormal external genitalia suggest outflow tract abnormalities.
 - Clitoral enlargement is a sign of virilization and raises suspicion for an androgen-secreting tumor or congenital adrenal hyperplasia.
 - The decision to do a digital or speculum pelvic exam should be based on the patient's age/maturity/gynecologic history/and ability to tolerate the exam. When presented with primary amenorrhea, an ultrasound should be used to evaluate anatomy (see the following discussion). An ultrasound may be needed as an adjunct to laboratory testing when evaluating secondary amenorrhea.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Standard initial testing: pregnancy test, FSH/LH, estradiol, TSH, free T₄, prolactin (8 a.m.)
- For primary amenorrhea, include genetic testing by checking a karyotype for sex chromosome abnormalities.
- If PCOS is suspected or virilization is identified, also include total and free testosterone, dehydroepiandrosterone-sulfate (DHEA-S), and 17-hydroxyprogesterone.
- If Cushing syndrome is suspected, consider an overnight dexamethasone suppression test or 24-hour urinary free cortisol excretion.

Imaging

- Imaging should be used selectively.
- Transvaginal or pelvic ultrasound
 - Confirm presence of normal müllerian structures (uterus and ovaries) for patients with primary amenorrhea.
 - Exclude ovarian mass and renal abnormalities based on abnormal physical exam or laboratory results.
- MRI of the pituitary gland if indicated based on neurologic symptoms, galactorrhea, and/or laboratory results (elevated prolactin)

DIFFERENTIAL DIAGNOSIS

- Pregnancy
- Outflow tract abnormalities
 - Imperforate hymen, transverse vaginal septum, müllerian agenesis, androgen insensitivity syndrome
- Ovarian failure
 - Chromosomal abnormalities and other inherited defects such as Turner syndrome and androgen insensitivity syndrome
 - Radiation- or chemotherapy-induced ovarian failure, autoimmune premature ovarian failure, idiopathic premature ovarian failure
- Chronic anovulation
 - Androgen excess: PCOS (common), congenital adrenal hyperplasia, ovarian or adrenal tumor
 - Elevated prolactin: prolactinoma, medications, hypothyroidism, others. Remember that stress can cause mild elevations in serum prolactin that are not pathologic.
 - Low or normal LH/FSH: chronic or systemic illness, eating disorders, extreme obesity, excessive exercise, psychological stress, hypopituitarism
 - Thyroid disease
 - Cortisol excess: Cushing syndrome
- Medications:
 - Cytotoxic, hormonal contraception, opiates, psychiatric medications, and others

TREATMENT

- Identification and management depends on the underlying disorder.
- Estrogen/progestin hormonal therapy may have a role but should not be initiated prior to completing a full evaluation.
- Premature use of hormonal therapy may alter subsequent testing.
- Contraindications to hormone therapy must be ruled out (refer to World Health Organization [WHO] Medical Eligibility Criteria at http://www.who.int/reproductivehealth/publications/family_planning/en)

ADDITIONAL THERAPIES

Behavioral interventions: An interdisciplinary team may be required to effectively manage eating disorders, complex behavior problems, or emotional symptoms.

FAQ

- Q: What are the normal benchmarks for evaluating pubertal development in girls?
- A: Normal benchmarks for evaluating pubertal development in girls: breast development by age 12–13 years, menarche ~2 years after breast development (by age 14 years), or menarche within 2 years of achieving Tanner IV breast stage
- Q: Does a patient who says she has never had sex still need a pregnancy test?

- A: Yes.

ANAEROBIC INFECTIONS

Hamid Bassiri

BASICS

DESCRIPTION

- Anaerobic bacteria are organisms capable of growing in a reduced oxygen environment, either exclusively (obligate anaerobes) or in addition to growing in air (facultative anaerobes).
- Anaerobic bacteria can cause invasive and serious diseases.
- Anaerobic bacteria tend to participate in polymicrobial infections with other anaerobic and aerobic flora.

EPIDEMIOLOGY

- Although anaerobic bacteremia is less frequent in children than in adults, other anaerobic infections such as chronic sinusitis or chronic otitis media are common in children.
- Because of their fastidious nature, the ability of microbiology laboratories to identify anaerobic bacteria is highly dependent on proper collection and transport of culture specimens; hence, anaerobic bacteria are often missed and likely underreported.

RISK FACTORS

- Impaired host immunity
 - Malignancy
 - Splenic dysfunction
 - Hypogammaglobulinemia
- Presence of devitalized tissue
- Surgery, trauma
- Vascular insufficiency
- Poorly controlled diabetes
- Presence of foreign bodies
- Colitis

PATHOPHYSIOLOGY

- Anaerobic infections commonly derive from the normal flora of the oropharynx, skin, intestines, or the female genital tract; thus, anaerobic infections occur when there is a loss of integrity of anatomic or epithelial barriers at these sites.
- Virulence factors include production of exotoxins (e.g., *Clostridia* spp.), endotoxins (e.g., *Fusobacterium* spp.), and presence of phagocyte-inhibiting capsules (e.g., *Bacteroides* spp.).

ETIOLOGY

- The most common clinically-relevant anaerobes include the following:
 - Gram-negative rods (*Bacteroides*, *Prevotella*, *Porphyromonas*, *Fusobacterium*)
 - Gram-positive cocci (*Peptostreptococcus*, *Peptococcus*)
 - Spore-forming gram-positive bacilli (*Clostridia*)
 - Non-spore-forming gram-positive bacilli (*Eubacterium*, *Bifidobacterium*, *Propionibacterium*, *Actinomyces*, *Lactobacillus*)
 - Gram-negative cocci (*Veillonella*, *Acidaminococcus*)
 - Spirochetes (many of which are anaerobic)

COMMONLY ASSOCIATED CONDITIONS

- CNS infections:
 - Brain abscess due to bacteremia
 - Subdural empyema
 - Epidural abscess (most commonly due to complications from sinusitis)
- Head and neck infections:
 - Sinusitis (generally polymicrobial)
 - Chronic otitis media
 - Ludwig angina (infection of the submandibular space)
 - Cervical adenitis
 - Peritonsillar abscess
 - Dental abscess
 - Gingivitis
 - Actinomycosis of jaw
 - Lemierre disease (septic thrombophlebitis of the internal jugular vein owing to anaerobic bacteremia, most commonly with

Fusobacterium spp., often resulting in pulmonary abscess formation)

- Pleuropulmonary infections:
 - Aspiration of infected amniotic or vaginal secretions in neonates
 - Aspiration of oral or gastrointestinal fluids in children (severe gingival or periodontal may be a risk factor)
 - Pneumonia, abscess formation due to aspirated foreign bodies
 - Actinomycosis
- Peritonitis/peritoneal abscess:
 - Appendiceal abscess
 - Perforated viscus
 - Postoperative complication
 - Trauma-related
 - Actinomycosis
- Cholangitis
 - Ascending infection may occur following biliary tract surgery (e.g., Kasai procedure)
- Soft tissue infections:
 - Paronychia
 - Pilonidal cyst
 - Hidradenitis suppurativa
 - Crepitant cellulitis
 - Necrotizing fasciitis
 - Gas gangrene (Clostridium spp.)
 - Infected decubitus ulcers (may result in contiguous osteomyelitis)
 - Penetrating wounds (may lead to tetanus)
- Infections of the female genital tract:
 - Endometritis
 - Salpingitis
 - Tubo-ovarian or adnexal abscess
 - Pelvic inflammatory diseases
 - Pelvic abscess
 - Bartholin gland, vulvar, or perineal abscess
 - Bacterial vaginosis
- Infected bite wounds

- Anaerobes isolated from 50% of human or animal bites
- Bacteremia
 - Often associated with focal primary site of involvement (gastrointestinal disease, abscess)
- Neonatal infections:
 - Cellulitis at fetal monitoring sites
 - Aspiration pneumonia
 - Omphalitis
 - Conjunctivitis
 - Infant botulism

DIAGNOSIS

Involvement of anaerobic bacteria should be suspected in infections with suppuration or foul smell, abscess formation, tissue necrosis, or in hosts with systemic disease or defective immunity.

HISTORY

- Impaired mental status
 - Increased risk of aspiration
- History of thumb sucking
 - Anaerobes frequently isolated from paronychia
- History of animal or human bites
- Recent surgery or trauma
 - Poor drainage or devitalized tissue associated with anaerobic infection
- Underlying immunodeficiency or chronic illness
 - Impaired phagocytic function
- History of pus that is “sterile” (no growth on routine cultures).

PHYSICAL EXAM

- Location of infection
 - See “[Commonly Associated Conditions.](#)”
- Poor dentition
 - Increased colonization of oropharynx with anaerobic organisms
- Necrotic tissue

- Crepitus with gas gangrene
- “Dishwater” pus or discharge with foul odor
 - Characteristic of anaerobic infections
- Lateral neck pain in association with respiratory distress:
 - Lemierre disease results in septic thrombophlebitis of the internal jugular vein and formation of lung abscesses; untreated or undiagnosed Lemierre disease carries a significant mortality rate.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Certain anaerobic bacteria have unique morphology on Gram stains:
 - Bacteroides spp.: small, pleomorphic gram-negative bacilli
 - Clostridium spp.: large gram-positive organisms with “boxcar” morphology
- Anaerobic cultures
 - Should be performed on tissue or aspirated fluid obtained directly from the infected sites in a sterile fashion
 - Anaerobically collected specimens should be transported to the laboratory promptly.
 - Swabs should not be sent for anaerobic cultures.

Imaging

- Radiographs may show the following:
 - Air–fluid levels
 - Cavity formation
 - Gas in tissue
- CT and/or MRI scans
 - Often important to define anatomic location and extent of disease, and to determine surgical approaches to drainage or debridement

TREATMENT

MEDICATIONS

Empiric antibiotics for anaerobic infections include the following:

- Metronidazole
- Carbapenems (e.g. meropenem or imipenem)

- Chloramphenicol (supplies in the United States may be limited)
- β -Lactam/ β -lactamase inhibitor combinations (e.g., amoxicillin-clavulanate, ampicillin-sulbactam, ticarcillin-clavulanate, or piperacillin-tazobactam)
- Clindamycin
- Cephamycins (e.g., cefoxitin or cefotetan)
- Vancomycin has activity against gram-positive but not gram-negative anaerobes.
- Penicillins, cephalosporins, tetracyclines, macrolides, aminoglycosides, trimethoprim-sulfamethoxazole, and monobactams have either variable or poor activity against anaerobes and should not be used empirically.
- Most fluoroquinolones also have variable activity, but exceptions exist (e.g., moxifloxacin).
- Antibiotic resistance is increasing in certain anaerobes, especially *Bacteroides* spp.; not all microbiology laboratories routinely test anaerobes for antibiotic susceptibility.
 - If a patient with a documented anaerobic infection does not appear to be responding to empiric therapy, it is advisable to consult with a infectious diseases specialist for further recommendations.

Empiric drug therapy reflects the polymicrobial nature of infections in which anaerobic bacteria are predominantly found:

- CNS infections
 - Vancomycin + 3rd or 4th generation cephalosporin (e.g., ceftriaxone) + metronidazole
 - Avoid using β -lactam-/ β -lactamase inhibitor combinations for brain abscesses, as β -lactamase penetration across blood–brain barrier may be suboptimal.
- Head and neck infections
 - Ampicillin-sulbactam, amoxicillin-clavulanate, or clindamycin alone if gram-negative aerobic bacteria are of little concern
- Pleuropulmonary infections due to aspiration
 - Ampicillin-sulbactam, amoxicillin-clavulanate, or clindamycin
- Peritonitis/peritoneal abscess
 - Ampicillin-sulbactam, ticarcillin-clavulanate, piperacillin-tazobactam, cefoxitin, meropenem, or imipenem

- Cholangitis
 - Piperacillin-tazobactam, meropenem, or imipenem
- Soft tissue infection
 - Clindamycin, ampicillin-clavulanate
- Infections of the female genital tract
 - Ampicillin-sulbactam, ticarcillin-clavulanate, piperacillin-tazobactam, cefoxitin, meropenem, or imipenem
- Infected bite wounds
 - Ampicillin-sulbactam, piperacillin-tazobactam, amoxicillin-clavulanate
- Bacteremia
 - Isolate-dependent, but it may be reasonable to start with vancomycin + 3rd or 4th generation cephalosporin (e.g., ceftriaxone) + metronidazole until isolate speciated and bacteremia confirmed to be due to anaerobic bacteria

COMPLEMENTARY & ALTERNATIVE THERAPIES

- Neutralization of toxins, especially in the case of botulism or tetanus, is critical.
- Hyperbaric oxygen, although still sometimes used (especially in clostridial infections), has not been shown to be of proven benefit, although it may help define and demarcate the borders of devitalized tissues.

SURGERY/OTHER PROCEDURES

- Effective drainage of abscesses and debridement of devitalized tissue is essential.
- Cultures should be obtained by aspirating fluids into sterile syringes, capping them, and transporting these to the laboratory promptly.
- Cultures can also be obtained from intact tissues that are transported to the laboratory promptly.
- Swabs should not be sent for anaerobic cultures.

ONGOING CARE

PROGNOSIS

- Determined by speed with which infection is appropriately treated with antibiotics and/or drainage
- High rates of morbidity and mortality associated with untreated anaerobic bacteremia
- Specific prognosis depends on the bacterial species involved and the status of the patient's immune system.
- Soft tissue infections, necrotizing fasciitis, or gas gangrene caused by *Clostridium* spp. may cause up to 20% mortality despite aggressive therapy.

COMPLICATIONS

- Vary with nature of infection, but can include extension of infection to adjacent structures
- Development of bacteremia

ANAPHYLAXIS

Benjamin T. Prince • Rachel G. Robison

BASICS

DESCRIPTION

- Anaphylaxis is a serious, life-threatening, systemic allergic reaction that is rapid in onset, and is a result of mast cell and basophil activation and degranulation.
- Skin and mucosal symptoms such as flushing, itching, urticaria, or angioedema are present in 80–90% of patients with anaphylaxis. Yet, absence of skin findings does not exclude anaphylaxis.
- In fatal anaphylaxis, initial signs and symptoms may include respiratory distress without urticaria resulting in delayed diagnosis and treatment.

EPIDEMIOLOGY

- 0.05–2% lifetime prevalence
- Rate of occurrence appears to be increasing.
- Estimated to be fatal in 0.7–2% of cases

RISK FACTORS

Genetics

There are few studies of genetic factors in human anaphylaxis; however, individuals with a previous history of anaphylaxis or a history of atopy are at increased risk for future anaphylaxis episodes.

PATHOPHYSIOLOGY

- In anaphylaxis, mast cells and basophils are activated via an IgE-mediated (most common) or non-IgE-mediated mechanism releasing preformed and newly generated mediators of inflammation.
 - Mediators include histamine, tryptase, proteoglycans, leukotrienes, prostaglandins, platelet-activating factor, and cytokines.
 - Local or systemic effects can include increased vascular permeability, vasodilation, smooth muscle contraction, complement

activation, and coagulation.

- IgE-mediated anaphylaxis occurs when IgE is synthesized in response to allergen exposure (sensitization) and becomes fixed to high-affinity IgE receptors located on the surface of mast cells and basophils. Subsequent allergen exposure results in receptor-bound IgE aggregation and cell activation.
- Non-IgE-mediated anaphylaxis generally results from nonimmune stimulation of mast cells or basophils. Rarely, IgG and complement can be implicated.

ETIOLOGY

- IgE-mediated:
 - Foods (peanut, tree nuts, fish, shellfish, milk, egg, wheat, soy)
 - Medications (antibiotics, especially, β -lactams, NSAIDs, biologic products)
 - Venoms (usually from stinging insects including fire ants)
 - Latex (direct exposure to natural rubber or ingestion of cross-reacting foods)
 - Other (vaccines, occupational allergens, and rarely inhaled allergens)
- Non-IgE-mediated:
 - Radiocontrast media (can also trigger IgE-dependent anaphylaxis)
 - Medications (opiates, NSAIDs, dextrans, vancomycin, polymyxin B)
 - Physical stimuli (exercise, cold, heat, sunlight/UV radiation)
 - Ethanol

DIAGNOSIS

Anaphylaxis is a clinical diagnosis that is considered highly likely when any one of the following three criteria is met:

- Acute onset of illness (minutes to hours) with involvement of skin, mucosa, or both and at least one of the following: (a) respiratory compromise or (b) reduced blood pressure or associated symptoms of organ dysfunction.

- Two or more of the following occurring acutely (minutes to hours) after exposure to a likely allergen: (a) involvement of skin-mucosal tissue (b) respiratory compromise (dyspnea, wheezing, stridor, hypoxemia), (c) reduced blood pressure or associated symptoms of organ dysfunction, (d) persistent gastrointestinal symptoms (abdominal cramping, vomiting).
- Reduced systolic blood pressure acutely (minutes to hours) after exposure to known allergen for that patient. Defined by age-specific normals or >30% decrease from patient's baseline

HISTORY

- A detailed history of exposures and events in minutes to hours prior to onset should be obtained after treatment is initiated.
- Any previous history of anaphylaxis?
 - Can help direct history and patient education, especially if epinephrine was indicated but not given or if a known allergen was not recognized
- Food triggers
 - Most common: peanut, tree nuts, fish, shellfish, milk, egg, wheat, soy, sesame, additives (spices, colorants, contaminants)
 - Foods need to be ingested for a reaction to occur, but rarely anaphylaxis can be caused by inhalation of aerosolized vapors from cooking or processing (fish and shellfish).
 - Gastrointestinal symptoms tend to be more prominent than in other etiologies.
- Medication triggers
 - Specifically inquire about NSAIDs, supplements, and herbal treatments.
 - β -Blockers and ACE inhibitors can increase severity and/or make treatment of anaphylaxis more difficult.

ALERT

For patients with anaphylaxis who are taking β -blockers or ACE inhibitors and have persistent hypotension and bradycardia despite epinephrine, consider giving glucagon.

- Insect stings

- If possible, attempt to identify the insect (honeybees leave stinger at sting site).
- All patients should be referred to an allergist, as immunotherapy is effective in preventing 98% of future anaphylactic reactions.
- Natural rubber latex
 - Latex-allergic patients can develop anaphylaxis after ingestion of cross-reactive foods including banana, kiwi, papaya, avocado, potato, and tomato.

PHYSICAL EXAM

- Skin and mucosa
 - Flushing, itching, conjunctival erythema, urticaria, angioedema
- Respiratory
 - Upper airway: nasal itching, congestion, rhinorrhea, sneezing, dysphonia, hoarseness, stridor, drooling (can be a sign of angioedema or obstruction)
 - Lower airway: tachypnea, cough, wheezing/bronchospasm, decreased peak expiratory flow
 - Cyanosis, respiratory arrest
- Cardiovascular system
 - Tachycardia or bradycardia (less common), hypotension, arrhythmias, shock, urinary or fecal incontinence, cardiac arrest
- Gastrointestinal
 - Abdominal pain/cramping, vomiting, diarrhea, dysphagia
- Central nervous system
 - Patients may appear uneasy or describe a sense of impending doom.
 - Altered mental status, confusion, tunnel vision

DIAGNOSTIC TESTS & INTERPRETATION

Anaphylaxis is a clinical diagnosis; however, certain tests can aid in confirming the diagnosis. Treatment of anaphylaxis should be initiated immediately if a patient presents with a clinical picture that is consistent with anaphylaxis.

Lab

- Serum total tryptase
 - Elevated 15 minutes to 3 hours after onset of anaphylaxis

- Elevated in patients with anaphylaxis due to injected medications, insect stings, and when hypotension is present
- Can be normal in anaphylaxis due to foods or in those who are normotensive
- Normal serum tryptase does not rule out anaphylaxis.
- Laboratory test that is routinely used in practice
- Plasma histamine
 - Elevated if measured 15–60 minutes after onset of anaphylaxis due to its short half-life
 - Blood sample requires special handling.
 - Normal level does not rule out anaphylaxis.
- Urine histamine and N-methylhistamine
 - 24-hour urine histamine and N-methylhistamine (metabolite) can be elevated in the context of anaphylaxis.

Imaging

Chest radiograph: may be useful to rule out foreign body aspiration, or congenital malformations of the respiratory or gastrointestinal tract

DIFFERENTIAL DIAGNOSIS

- Allergic/atopic
 - Acute urticaria
 - Acute asthma
 - Pollen-food syndrome
- Cardiovascular
 - Myocardial infarction
 - Pulmonary embolus
- Genetic/metabolic
 - Hereditary or acquired angioedema
- Infectious
 - Septic shock
- Neoplastic
 - Mastocytosis/clonal mast cell disorders
 - Carcinoid
 - Basophilic leukemia
 - Pheochromocytoma

- Neurologic
 - Syncope
 - Seizure
- Nonorganic disease
 - Panic attack
 - Vocal cord dysfunction
 - Munchausen syndrome
- Other:
 - Foreign body aspiration
 - Scombroidosis (ingestion of fish containing high levels of histamine)
 - Red Man syndrome

TREATMENT

MEDICATION

First Line

- IM epinephrine 1:1,000 (1 mg/mL) solution
 - 0.01 mg/kg, maximum of 0.3 mg (child) or 0.5 mg (adult), repeated q5–15min as needed (most respond to 1 or 2 doses)
 - Many deaths from anaphylaxis are associated with delayed administration of epinephrine.

Second Line

- Diphenhydramine IV or PO (or equivalent H₁-antihistamine)
 - 1 mg/kg, maximum of 50 mg, q4–6h
- Albuterol 2.5 mg/3 mL solution
 - Nebulized and inhaled via face mask
- Ranitidine IV
 - 1 mg/kg, maximum 50 mg
- Methylprednisolone IV (or equivalent glucocorticoid)
 - 1–2 mg/kg, maximum of 60 mg (may be continued PO once daily for 1- to 3-day course)
 - Thought to prevent biphasic or protracted anaphylaxis, but unlikely to provide benefit in initial minutes of anaphylaxis

ADDITIONAL TREATMENT

General Measures

- Maintain airway:
 - Supplemental oxygen
 - Bag mask or intubation if necessary
- Maintain circulation:
 - Place patient supine and elevate lower extremities if possible.
 - Volume resuscitation with 0.9% saline
 - IV vasopressors may be necessary in patients with refractory hypotension or shock.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Most patients who are diagnosed with anaphylaxis will benefit from a referral to an allergist/immunologist for further evaluation, recommendations, and management.

Patient Monitoring

Biphasic anaphylaxis, in which symptoms recur within 1–72 hours (usually 8–10 hours) after resolution of initial symptoms, occurs in up to 23% of adults and up to 11% of children with anaphylaxis.

- A prescription for autoinjectable epinephrine should be provided on discharge in any patient diagnosed with anaphylaxis.
- A 1- to 3-day course of oral steroids may prevent or limit biphasic or protracted anaphylaxis.
- Medical monitoring after return to baseline should be individualized and depend on degree of symptoms and other risk factors.
 - Patients with moderate respiratory compromise should be monitored for a minimum of 4 hours or longer if indicated (especially young patients or patients with comorbidities).

PATIENT EDUCATION

All patients should be instructed on allergen avoidance measures and provided with a written personalized emergency plan detailing appropriate management of future anaphylactic episodes.

PROGNOSIS

Good with trigger identification and avoidance

COMPLICATIONS

- Laryngeal edema and airway obstruction
- Pulmonary edema, pulmonary hemorrhage, and pneumothorax
- Myocardial ischemia and infarction
- End-organ ischemia and damage
- Death secondary to airway obstruction (asphyxiation) and/or shock

CODES

ICD10

- T78.2XXA Anaphylactic shock, unspecified, initial encounter
- T78.00XA Anaphylactic reaction due to unspecified food, init encntr
- T63.891A Toxic effect of contact with other venomous animals, accidental (unintentional), initial encounter

FAQ

- Q: Can a patient have an anaphylactic reaction on first exposure to an allergen?
- A: In IgE-mediated anaphylaxis, a patient must have been previously

exposed to the offending allergen for sensitization to occur with a subsequent exposure potentially resulting in anaphylaxis. Remember, however, that the absence of a previous exposure on history does not exclude an allergen as causal because sensitization may have previously occurred unknowingly (through skin contact, in breast milk, in utero). Non-IgE-mediated anaphylaxis can occur on first exposure to the offending allergen.

- Q: Should patients with a history of anaphylaxis carry more than one autoinjectable epinephrine device?
- A: Yes, up to 20% of patients with anaphylaxis are reported to require a second dose of epinephrine either because of ongoing symptoms or because of biphasic anaphylaxis.
- Q: Can a patient develop anaphylaxis to an allergen that they have tolerated previously?
- A: Yes, this often occurs with medications or foods (particularly peanut, tree nuts, fish, and shellfish) especially if there is a long period of time between exposures.

ANEMIA OF CHRONIC DISEASE (ANEMIA OF INFLAMMATION)

Michele P. Lambert

BASICS

DESCRIPTION

Anemia that accompanies a variety of systemic diseases, with the common features of chronicity and inflammation. Anemia of chronic disease is more properly called anemia of inflammation (AI) and is the combined result of mildly increased destruction of RBCs, relative erythropoietin resistance, and iron-restricted erythropoiesis.

PATHOPHYSIOLOGY

Typically mild to moderate anemia (Hgb 7–12 g/dL); develops in the setting of infection, inflammatory disorders, and some malignancies

- Deficient cellular iron in the setting of hepcidin excess (functionally inaccessible iron)
- Typically normochromic, normocytic but, if long-standing, can be hypochromic, microcytic (especially in children)
- Main mechanism appears to be
 - Iron restriction (limited iron supply to erythropoiesis)
 - Hepcidin is increased by interleukin 6 (IL-6) and causes depletion of the only known membrane iron transporter (ferroportin).
 - These changes result in cellular inability to release stored iron and enterocyte inability to absorb iron because of inability to transport iron over cell membrane into bloodstream.
- Other factors contributing to anemia in various degrees include the following:
 - Increased red cell destruction
 - Diagnostic phlebotomy or other blood loss
 - Cytokine-mediated interference with erythropoietin signaling
 - Cytokine-mediated suppression of erythropoiesis
 - Cytokines such as interleukin-1 (IL-1) and IL-6 can activate ferritin

synthesis. The ferritin can lead to sequestration of iron, which eventually is converted into hemosiderin.

ETIOLOGY

Underlying disease process

COMMONLY ASSOCIATED CONDITIONS

- Underlying disease process
 - Infections, both acute and chronic
 - Inflammatory disease
 - Collagen vascular diseases
 - Malignancies
 - Renal failure
- Anemia of chronic disease often coexists with other causes of anemia, including occult blood loss, hemolysis, dietary iron deficiency, and drug-related marrow suppression.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Various abnormal physical findings may be present, depending on the underlying chronic disease process.
- May have mild pallor but will not have signs of circulatory collapse
- Similar disease can be seen more acutely in the setting of anemia of critical illness (also part of AI).

HISTORY

Anemia develops over the 1st month of the underlying disease process and then remains fairly stable over time.

PHYSICAL EXAM

- Mild pallor
- Mild tachycardia, may be inapparent at rest
- Very rarely more overt signs of anemia such as flow murmur, gallop, or hepatomegaly
- Physical findings of the underlying disease

DIAGNOSTIC TESTS & INTERPRETATION

If only the serum iron is obtained, without other iron studies, the child may be inappropriately diagnosed with iron deficiency.

Lab

- CBC with indices
 - Normocytic, normochromic (can be microcytic, hypochromic when very long-standing) anemia with hematocrit rarely <20%
 - Reticulocyte count usually in the normal range, but low for the level of anemia.
- Iron studies
 - Low plasma iron, with low total iron-binding capacity
 - Low transferrin saturation by iron
 - Normal or high ferritin level
- Elevated free erythrocyte protoporphyrin
- Hemosiderin in bone marrow macrophages is increased if bone marrow aspiration is done and the aspirate is viewed with iron stains.
- Albumin and transferrin are both low.
- Acute-phase reactants such as C-reactive protein may be elevated.
- Hepcidin levels will be elevated.

Diagnostic Procedures/Other

Bone marrow aspiration is generally not indicated.

DIFFERENTIAL DIAGNOSIS

Anemia of chronic disease is often confused with iron deficiency anemia.

- In anemia of chronic disease:
 - Mild to moderate anemia
 - Mild anisocytosis
 - Usually normochromic, normocytic but can be hypochromic with microcytosis
 - Decreased plasma iron
 - Decreased iron-binding capacity
 - Normal or slightly low transferrin saturation
 - Decreased marrow sideroblasts
 - Normal or elevated reticuloendothelial iron
 - Elevated free erythrocyte protoporphyrin

- Normal or elevated ferritin
- Increased hepcidin
- In iron deficiency:
 - Decreased plasma iron
 - Increased iron-binding capacity
 - Decreased transferrin saturation
 - Decreased marrow sideroblasts
 - Decreased reticuloendothelial iron
 - Increased free erythrocyte protoporphyrin
 - Decreased serum ferritin
 - Decreased hepcidin
- In both iron deficiency and anemia of chronic disease:
 - Decreased plasma iron
 - Decreased transferrin saturation
 - Decreased marrow sideroblasts
 - Elevated free erythrocyte protoporphyrin
 - Decreased reticulocyte count
- Tests that help differentiate iron deficiency from anemia of chronic disease:
 - Iron-binding capacity
 - Serum ferritin
 - Reticuloendothelial iron stain in marrow
 - Hepcidin level (although not available everywhere)

TREATMENT

GENERAL MEASURES

- Iron
 - Generally, no role for iron therapy unless there is coexisting iron deficiency anemia. However, recent studies in patients with renal disease have shown improved response to erythropoietin with coadministration of parenteral iron.
- Recombinant human erythropoietin
 - Effective, but indications for use are still not universally accepted
 - Often used in chronic renal failure

- Has been used in inflammatory bowel disease, with good results
- Should be used for more severe and symptomatic anemia in which the underlying disease is likely to be prolonged and difficult to treat
- Treatment should be directed at the underlying disease process.

SPECIAL THERAPY

Transfusion of packed RBCs is sometimes indicated intermittently in severe anemia with hemodynamic compromise.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

Treatment of underlying disease process may promote slow resolution of associated anemia. Hematocrit increases ~6–8 weeks after start of recombinant human erythropoietin therapy; continues to rise over 6 months.

COMPLICATIONS

If severe, patients may be transfusion dependent and, thus, be at risk for complications associated with packed RBC transfusions.

CODES

ICD10

- D63.8 Anemia in other chronic diseases classified elsewhere
- D63.1 Anemia in chronic kidney disease
- D63.0 Anemia in neoplastic disease

FAQ

- Q: Does anemia that is associated with a chronic disease require further evaluation?
- A: If the anemia fits within the usual expectations for the patient's diagnosis, there is no need to pursue further investigation, except in specific cases. If there is an associated malignancy for which marrow metastasis is possible, a bone marrow aspirate and biopsy should be done. In conditions with malabsorption, nutritional deficiencies and blood loss should be ruled out.

ANKYLOGLOSSIA

Timothy R. Shope • Robert F. Yellon • Melissa A. Buryk

BASICS

DESCRIPTION

Anatomic variation of the tongue in which the lingual frenulum is unusually tight and short. Also known as tongue-tie. This condition may result in impaired tongue mobility with early breastfeeding problems, maternal nipple pain, and, later, speech problems.

EPIDEMIOLOGY

- Incidence ranges from 1.7 to 5% of newborns in various studies.
- About half of breastfeeding infants with ankyloglossia will have difficulty feeding or cause maternal nipple pain during feeds.
- Incidence of speech articulation disorders due to ankyloglossia is unknown.
- Male-to-female ratio of 3:1.

RISK FACTORS

- Pedigree analysis suggests significant hereditary component, possibly X-linked.
- Studies show 40–50% of patients with ankyloglossia had a relative with the same condition and an inheritance rate of about 21%.
- Rarely, mutations in the T-box transcription factor TBX22 may lead to heritable ankyloglossia with or without cleft lip, cleft palate, or hypodontia.
- Rarely, may be associated with Opitz syndrome or orodigital facial syndrome
- No known environmental risk factors

PATHOPHYSIOLOGY

- Newborns with ankyloglossia
 - Are often asymptomatic but problems can occur with breastfeeding
 - May have poor or ineffective latch or may cause maternal nipple

- pain due to poor tongue mobility and prolonged feeding times
- Later in childhood, the effect of ankyloglossia is controversial.
 - May cause problems with articulation of certain sounds that require tongue to reach teeth, palate, and lips (e.g., “t,” “d,” “z,” “s,” “th,” “n,” “l”)
 - Not a cause of speech delay
 - May also result in mechanical problems including difficulty with oral hygiene (inability to lick lips), inability to lick ice cream cone, play wind instruments, or French kiss

DIAGNOSIS

Diagnosis based on physical appearance and functional impairment of breastfeeding or speech

HISTORY

- Maternal report of difficulty with infant latch or nipple pain while breastfeeding
- Report of inability of infant/child to extrude tongue beyond alveolus/teeth
- Ankyloglossia varies in severity. Some children can protrude tongue past alveolus/teeth but not past lower lip and still have difficulties.

PHYSICAL EXAM

- Commonly missed finding on newborn exam because the mouth is usually not open.
- Examiner should pass the small finger, pad-side down, under the infant’s tongue to feel for resistance at the site of the lingual frenulum.
- Examiner should also visualize the floor of mouth and lingual frenulum using tongue depressors, Q-tips, or fingers to open the mouth or by observation of the infant crying.
- Visualization of the tongue will show
 - Abnormally short frenulum, inserting at or near the tip of the tongue
 - Difficulty lifting tongue to upper alveolus/palate
 - Inability to protrude tongue beyond lower alveolus/teeth
 - Notching or heart shape of tip of tongue when protruded

- Note: Some children can protrude tongue past alveolus/teeth but not past lower lip and still have difficulties.

DIAGNOSTIC TESTS & INTERPRETATION

Imaging

- No imaging indicated
- Functional ultrasound of tongue movement during breastfeeding has been used experimentally to quantify milk transfer.

Diagnostic Procedures/Other

- Mothers of infants with ankyloglossia and difficulty breastfeeding should meet with lactation consultant to rule out other potential causative factors,
- Children with speech articulation difficulty should meet with speech therapist for therapy and to assess for other causes.

DIFFERENTIAL DIAGNOSIS

- Consider other causes of poor breastfeeding including inexperience, poor positioning, or poor suck.
- Consider other causes of speech articulation difficulties including incoordination and neuromuscular disease.

TREATMENT

GENERAL MEASURES

- Observation if there is no functional impairment of breastfeeding or speech
- Surgical treatment if functional impairment is present
- Treatment is frenotomy—incision of lingual frenulum.
 - For most healthy newborns, this may be performed in an outpatient setting. Topical lidocaine and oxymetazoline on a cotton ball are applied before and after incision with sterile scissors. Infants with a thick frenulum should have the procedure performed in the operating room setting to avoid bleeding.
 - For older children unlikely to cooperate, and any patient with medical comorbidities or coagulopathy, the procedure should be

performed in the operating room under general anesthesia.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Infants should be seen about one week after frenotomy to assess feeding and weight gain.
- Older children should be seen about 6 weeks after surgery to assess function and to determine whether a revision procedure for scar formation is needed.

PROGNOSIS

- Infants treated for tongue-tie have an excellent prognosis.
- <1% require repeat frenotomy and local flaps may be required.
- Frenotomy has been shown to be effective for improving infant breastfeeding problems and weight gain and maternal nipple pain while breastfeeding. There are 5 randomized controlled trials with similar positive results.
- Breastfeeding rates in infants treated with frenotomy for ankyloglossia appear similar to healthy infants (approximately 40–45% at 6 months and 25% at 12 months).
- There is anecdotal clinical evidence that frenotomy improves speech articulation problems. However, studies evaluating this are of low quality, with lack of randomization and small sample sizes. Further studies are needed.
- Complications have rarely been reported including severe infection or severe bleeding. Severe bleeding was associated with untrained individuals performing the surgery.

CODES

ICD10

- Q38.1 Ankyloglossia
- P92.8 Other feeding problems of newborn

FAQ

- Q: What is the appropriate time to perform frenotomy in breastfeeding newborns with ankyloglossia?
- A: Optimal timing is not known. A reasonable approach is to allow enough time to establish that there is a problem with breastfeeding caused by the ankyloglossia. Some infants with ankyloglossia will not have problems. Usually, this issue is evident in the first 2 days of life. Newborns with identified breastfeeding difficulty should have frenotomy performed quickly to allow for continued breastfeeding. Delay may cause some mothers to abandon breastfeeding due to pain or difficulty. Optimal timing is probably between 2 and 7 days of life.
- Q: In infants with ankyloglossia who are either bottlefeeding or breastfeeding with no difficulty, should frenotomy be performed to help “prevent” future problems with speech or functional difficulties?
- A: Data regarding speech/functional outcome in these children are not known at present.
- Q: Who does frenotomies?
- A: ENT or oral surgeons most commonly perform the procedure. In areas where access to these specialists is difficult, general

pediatricians, family practitioners, neonatologists, or newbornists may perform the procedure after sufficient training and appropriate credentialing. The procedure is not difficult. It can be done in the inpatient or outpatient setting. It is billed under the CPT Code 41010 (frenotomy).

- Q: What are the postoperative instructions after frenotomy?
- A: For all patients after frenotomy: acetaminophen for pain. Although complications are rare, patients should go to an emergency department if bleeding, infection, or swelling occurs. For older children, avoid citrus; spicy; or hard, scratchy foods for 1 week after the procedure.

ANOMALOUS LEFT CORONARY ARTERY FROM THE PULMONARY ARTERY (ALCAPA)

Shellie M. Kendall

BASICS

DESCRIPTION

The anomalous coronary artery arises from the pulmonary artery rather than the aorta. Most commonly, the anomalous left coronary artery arises from the pulmonary artery in a condition known as ALCAPA or Bland-White-Garland syndrome.

EPIDEMIOLOGY

Incidence

Very rare anomaly, occurring in 0.25% of congenital heart disease

Prevalence

The majority of patients present in infancy at approximately 2 months of age (when pulmonary vascular resistance is falling). There are case reports of patients presenting as late as the 4th–7th decades of life.

PATHOPHYSIOLOGY

- In the fetal and neonatal period, pulmonary artery pressure is increased owing to elevated pulmonary vascular resistance. This elevated pulmonary artery pressure provides antegrade flow from the pulmonary artery through the anomalous coronary artery.
- As pulmonary vascular resistance drops, pulmonary arterial pressure drops. When the diastolic blood pressure in the pulmonary artery decreases below myocardial perfusion pressure (or diastolic aortic pressure), pulmonary run-off “steals” blood from the myocardium, resulting in myocardial ischemia of the anterolateral left ventricular wall and mitral valve papillary muscle dysfunction.
- The fact that the left ventricle is perfused with desaturated blood plays a less important role than the overall perfusion-related imbalance

between myocardial oxygen demand and supply.

ETIOLOGY

- Abnormal septation of the conotruncus into the aorta and pulmonary artery
- Persistence of the pulmonary buds and involution of the aortic buds that usually eventually form the coronary arteries
- As-yet-unspecified genetic predisposition

DIAGNOSIS

HISTORY

- Typically presents with paroxysms of poor feeding, pallor, tachypnea, respiratory distress, and diaphoresis
- Irritability, crying, appearance of being in pain (especially after meals)
- Can be asymptomatic
- Can be symptomatic in infancy and then gradually improve (with the development of adequate coronary collateralization)
- Older children and adults may have dyspnea, syncope, or angina pectoris.
- Sudden death

PHYSICAL EXAM

- Signs of congestive heart failure (CHF) such as cachexia, tachycardia, tachypnea, lethargy, diaphoresis
- Signs of low cardiac output such as pallor, diminished peripheral pulses and perfusion
- Gallop rhythm
- Loud P₂ component of S₂ (if left ventricular heart failure raises pulmonary arterial pressure)
- Murmur of mitral regurgitation or a continuous murmur reminiscent of a coronary arteriovenous fistula
- Diagnosis should be entertained in any infant presenting with cardiomegaly or perplexing cardiorespiratory symptoms.

DIAGNOSTIC TESTS & INTERPRETATION

Imaging

- Chest radiograph: cardiomegaly, pulmonary edema
- Electrocardiography: anterolateral infarct pattern in an infant (Q in I, aVL, V₄–V₆), abnormal R-wave progression in precordial leads
- Echocardiogram: attachment of coronary artery to pulmonary artery by 2-dimensional imaging. Doppler interrogation shows flow passing from coronary artery to great artery rather than vice versa (if pulmonary vascular resistance has fallen).
 - Dilation of the right coronary artery
 - Left ventricular function impairment, wall motion abnormalities, and dilation
 - Mitral regurgitation
 - Echogenic papillary muscles
- Coronary CT angiography
 - Excellent diagnostic modality for older patients with slower heart rates, allowing better resolution
 - Emerging CT technology is allowing this technique to be used in infancy with lower radiation doses and excellent resolution.
- Nuclear imaging: Thallium myocardial perfusion imaging shows reduced uptake in ischemic regions.
- Cardiac catheterization: Angiographic and hemodynamic parameters may correlate with degree of cardiovascular dysfunction.
 - Low cardiac output
 - High left atrial filling pressures
 - Pulmonary arterial hypertension
 - Aortic root angiography shows passage of contrast medium from normally connected right coronary artery to the left coronary arterial system to the pulmonary artery.
 - Pulmonary artery angiogram shows reflux of contrast medium into the left coronary artery and/or a “negative wash-in” of unopacified blood flowing from left coronary to pulmonary artery.

DIFFERENTIAL DIAGNOSIS

- Cardiomyopathy
- Myocarditis
- Coronary artery fistula

- Left ventricular failure from other causes
- Mitral valve regurgitation
- Respiratory distress from other causes
- Colic

TREATMENT

GENERAL MEASURES

The first priority is to safely institute supportive care measures while expeditiously planning for surgical intervention.

SURGERY/OTHER PROCEDURES

- Direct reimplantation of the left coronary artery into the aorta using a button of pulmonary arterial tissue and/or an extension-tube graft of anterior and posterior pulmonary arterial wall tissue sewn into a narrow cylinder to avoid tension, distortion, and stenosis of the coronary
- Creation of an aortopulmonary window and tunnel that directs blood from aorta to the left coronary ostium (Takeuchi procedure).
- Ligation of the origin of the left coronary artery and reconstitution of flow with saphenous or internal mammary graft rarely used in the current era.
- Ligation of the origin of the left coronary artery (to prevent flow runoff into the pulmonary artery or “steal”) is rarely ever used, even in very ill infants.

INPATIENT CONSIDERATIONS

Initial Stabilization

- Attention to basic life support measures (airway, breathing, and circulation) and prompt referral to a pediatric cardiac center are indicated immediately on presentation.
- As myocardial ischemia can be worsened with traditional heart failure treatments such as oxygen administration, afterload reduction, and inotropic support, these therapies should be administered in consultation with a pediatric cardiac care center.
- An excess of procedures, interventions, and manipulation is poorly

tolerated by this group of critically ill patients.

ONGOING CARE

PROGNOSIS

- Untreated, 90% of those who present in infancy will die before the age of 1 year, usually at 1 to 2 months of age (when pulmonary vascular resistance falls).
- Very few of those who present early improve spontaneously.
- Late results after surgery are excellent in many centers. Hospital mortality in larger selected series of these frequently moribund patients is $\leq 5\%$, with very little subsequent attrition.
- Mitral regurgitation usually improves after surgery establishes a patent dual-coronary system, but this may take 6–12 months to be fully realized. Follow-up evaluation is warranted, as mitral regurgitation may progress despite surgery, and valve repair may be required later.

CODES

ICD10

Q24.5 Malformation of coronary vessels

FAQ

- Q: How do you differentiate crying from the symptoms of myocardial ischemia from crying from colic?
- A: This is not easy, but clinical assessment should manifest the signs of CHF, shock, and low cardiac output, which are decidedly atypical for the usual patient with colic. If the patient is still feeding, the crying in patients with this lesion classically occurs after meals, when blood is shunted to the liver and intestines. This is not a highly sensitive finding, and concern should lead to further objective evaluation.

ANOREXIA NERVOSA

Darlene Atkins • Sara M. Buckelew

BASICS

DESCRIPTION

Anorexia nervosa (AN) is a complex biopsychosocial illness.

- Diagnostic and Statistical Manual of Mental Disorders 5th edition (DSM-5) criteria:
 - Restriction of energy intake relative to requirements, leading to a significantly low body weight in the context of age, sex, developmental trajectory, and physical health. Significantly low weight is defined as weight that is less than minimally normal or, for children and adolescents, less than minimally expected.
 - Intense fear of gaining weight or becoming fat, or persistent behavior that interferes with weight gain, even though at a significantly low weight
 - Disturbance in the way in which one's body weight or shape is experienced, undue influence of body weight or shape on self-evaluation, or persistent lack of recognition of the seriousness of current low body weight
- Types: Restricting (no binge eating or purging) or binge eating/purging (purging includes vomiting, laxatives and/or diuretic use)
- Reprinted with permission from the American Psychiatric Association. Diagnostic and Statistical Manual of Mental Disorders. 5th ed. American Psychiatric Association; 2013:171.

EPIDEMIOLOGY

Prevalence

- Approximately 0.5% of adolescent girls in the United States have AN.
- 10% of all patients with eating disorders are males.
- In younger patients, approximately equal numbers of females and males
- Increasing prevalence of eating disorders is seen in preadolescents, in males, and in minority populations within the United States.

RISK FACTORS

- Early physical/pubertal development
- Personality traits such as perfectionism and eagerness to please
- Family history of eating disorders, alcoholism, or mood disorders
- Involvement in sports or activities that emphasize shape/weight
- “Dieting” itself is a risk factor for developing an eating disorder.

Genetics

Family studies demonstrate that 1st-degree relatives have a 10-fold increased lifetime risk of developing AN. Twin studies also support role of genetics and familial concordance of AN.

GENERAL PREVENTION

- Assess height, weight, and BMI at every preventive visit at a minimum; evaluate for deviations.
- Discourage “dieting” behavior. Instead, focus on promoting healthy eating behaviors and lifestyle change.
- Strongly encourage regular family meals. Research supports this as a protective factor for all types of eating disorders and obesity.

PATHOPHYSIOLOGY

- Physical manifestations are primarily the result of caloric restriction and consequences of malnutrition, which can affect all organ systems. The degree of symptoms seen may be due in part to the duration and severity of caloric restriction.
- Associated changes may also be due to purging, including vomiting, laxative use, or diet pill use.
- Bradycardia and hypothermia may result from significantly decreased metabolic rate due to malnutrition and caloric restriction.
- Hormonal changes due to starvation include resumption of prepubertal gonadotropin secretion.

ETIOLOGY

Evidence for specific etiology is not definitive; most likely multifactorial, including genetic risk factors, environmental triggers, and individual and family life experiences

COMMONLY ASSOCIATED CONDITIONS

- Amenorrhea
- Osteopenia/osteoporosis
- Female athlete triad (disordered eating, amenorrhea, osteoporosis)
- Depression
- Anxiety disorders including obsessive-compulsive disorder
- Substance abuse

DIAGNOSIS

Diagnosis is made using DSM-5 criteria. However, many patients exhibit marked symptoms but do not meet the full criteria for AN; for example, despite drastic weight loss, the patient's weight remains in the normal range. These patients may be diagnosed with other specified feeding or eating disorder, also called subclinical or atypical anorexia nervosa. These patients likely still require close monitoring and potential intervention.

HISTORY

- Weight history: highest and lowest weight in last year; patient's "target weight" they were attempting to reach with restriction. Ask, "How often do you weigh yourself? What is the most you have weighed in past year? The least? What do you think of as your own ideal weight?"
- Psychological assessment: interviews with patient and parents, detailed history of body image concerns, obsession with weight and/or shape, developmental and family history, social and academic history, cognitive and personality traits, and premorbid and current level of functioning. Critical in establishing a diagnosis and developing a treatment plan.
- Other psychological symptoms: Assess mood and anxiety symptoms, suicidal ideation, substance use, and other risky or self-injurious behaviors.
- Diet and nutrition history: 24-hour dietary recall, history of binge eating, purging (including use of diuretics, laxatives, diet pills, or emetics), food restrictions, or calorie counting
- Exercise history: type, how much and intensity.
- Menstrual history: last menstrual period (LMP), weight at LMP,

history of skipped periods

PHYSICAL EXAM

- Vital signs, specifically orthostatic heart rates (HR) and blood pressures (to evaluate for vital sign instability that may be an indicator of severity and need for inpatient management), and temperature
- Weight, height, and BMI plotted in comparison to historical growth curve.
- HEENT: evaluate for signs of dehydration, dental exam for erosion due to purging
- CV: cardiac status
- GI: evaluate for pain, tenderness, organomegaly
- Derm: lanugo, Russell sign (callousing of the finger from self-induced purging), evidence of self-injurious behavior
- GU: Tanner staging for pubertal development
- Neurologic: complete exam including fundoscopic exam to rule out brain tumor

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Serum electrolytes, BUN/creatinine, glucose: typically normal if patient is not purging
- Serum calcium, magnesium, phosphorous: May all be low. If hospitalized, follow phosphorous daily to assess for refeeding syndrome.
- TSH; if indicated, free T₄, T₃: to rule out thyroid disease. If abnormal, may be due solely to starvation.
- CBC with differential: Anemia may be present due to iron deficiency or chronic disease but may be falsely normal if patient is dehydrated; low WBC count is seen with malnutrition.
- ESR: generally low due to malnutrition
- AST, ALT: occasionally abnormal due to fatty liver
- β -hCG): Rule out pregnancy if amenorrheic.
- Urinalysis: Evaluate specific gravity to assess for dehydration or may have dilute urine if patients water load to falsely increase their weight.
- Consider EKG: may demonstrate bradycardia, prolonged QTc

- Patients amenorrheic for >6 months:
 - Dual-energy x-ray absorptiometry (DEXA) scan: Evaluate bone density, risk of compression fracture, and bone loss. May be helpful motivator for treatment as may not be reversible.
 - Serum LH, FSH, prolactin, if persistent amenorrhea with normal weight: LH and FSH will generally be low.

DIFFERENTIAL DIAGNOSIS

- Medical conditions such as
 - Pregnancy
 - Oncologic: brain tumor, other cancers
 - GI: inflammatory bowel disease (including Crohn and ulcerative colitis), celiac disease
 - Endocrinologic: diabetes mellitus, thyroid disease, hypopituitarism, Addison disease
 - HIV or other chronic infections
- Psychiatric or psychological conditions such as
 - Psychiatric: depression, obsessive-compulsive disorder, substance abuse, psychotic symptoms
 - DSM-5 avoidant/restrictive food intake disorder: food aversions/hypersensitivity, extreme picky eating, decreased intake due to fears of swallowing/choking

TREATMENT

- Multidisciplinary team approach is considered the state of the art standard of care and includes medical monitoring, nutritional counseling, and psychological treatments.
- Family-based treatment (FBT) is the only evidence-based psychological treatment for pediatric and adolescent AN. Parents/caregivers are viewed as an integral part of the treatment team.
- Initially, all meals and snacks are prepared by and supervised by the parents. Gradually, age appropriate autonomy regarding eating is returned to the child/adolescent as physical and psychological progress is made.

MEDICATION

- Medications are not the primary mechanism for treating AN but may be helpful in the treatment of co-occurring illnesses such as depression and anxiety.
- Medications to treat constipation may be necessary but should be used with caution.
- Supplements such as multivitamin, calcium, and vitamin D should be considered.
- Refeeding is the treatment of choice for amenorrhea rather than starting oral contraceptive pills (OCPs).

ISSUES FOR REFERRAL

Depending on severity and availability, refer to an adolescent medicine specialist or other eating disorder specialist.

INPATIENT CONSIDERATIONS

Admission Criteria

- Criteria for inpatient hospitalization:
 - Severe malnutrition with weight <75% ideal body weight or weight loss despite treatment
 - Bradycardia including daytime HR <50 bpm
 - Nighttime HR <45 bpm
 - Systolic blood pressure <90 mm Hg
 - Orthostatic hypotension or significant orthostatic changes in pulse
 - Severe hypothermia (temperature <96°F)
 - Arrhythmia
 - Acute food refusal
 - Severe electrolyte abnormalities.
- Suicidality may require psychiatric hospitalization.

Discharge Criteria

Once a patient is medically stable and no longer meets admission criteria, insurance companies may limit lengths of hospital stays. Most patients are treated solely as outpatients.

ONGOING CARE

- Ongoing medical monitoring with emphasis placed on overall vital signs and not on weight alone
- Goals are set for nutritional rehabilitation. Meal plans are established and reassessed at each subsequent visit.
- Referral to a family therapist with this expertise is advised. Individual psychotherapy may be useful for many patients also particularly given the anxiety that is typically generated by the refeeding process.
- Group psychotherapy can be a useful adjunct particularly for some older adolescent patients.
- More intensive services include intensive outpatient, day, or residential treatment.
- Other adjunctive therapies include mindfulness training, expressive arts, etc.

PROGNOSIS

- Most adolescent patients recover fully but generally not without a long course of treatment. Overall, children and adolescents have better outcomes than adults.
- Better outcomes are associated with shorter duration of symptoms, earlier diagnosis, absence of purging behaviors, and less severity of psychiatric comorbidity. However, outcome findings vary depending on factors such as length of follow-up and definitions of recovery.
- Mortality rates for adolescents with AN are reported to be 1.8%, primarily from effects of starvation or from suicide.

COMPLICATIONS

- Majority of complications may be reversed with improved nutrition.
- Refeeding syndrome: As the patient is refed, the body may shift from a catabolic state to an anabolic state, resulting in a release of insulin which may drive phosphorous and potassium intercellularly and drop extracellular levels resulting in delirium, coma, arrhythmias, cardiac failure, and death.
- CV: arrhythmias, pericardial effusions
- GI: delayed gastric emptying, slowed intestinal motility and constipation, pancreatitis; elevated cholesterol
- Endocrine: amenorrhea, osteoporosis, sick euthyroid syndrome, growth

delay

- Complications related to purging include Mallory-Weiss tears, esophagitis, electrolyte and fluid imbalances (particularly hypokalemia)
- Neuropsychological: anxiety, poor concentration, depressed mood, cognitive impairment, cortical atrophy

- F50.01 Anorexia nervosa, restricting type

- F50.02 Anorexia nervosa, binge eating/purging type

FAQ

- Q: If the patient presents with severe low mood, why not start them on an antidepressant right away?
- A: Many of their depressive symptoms may be secondary to the effects of their malnourished state. It's best to begin nutritional rehabilitation and reassess as intake improves.
- Q: Can patients have AN if they do not report feeling fat or intentionally dieting?
- A: Yes. Denial is very often associated with AN. Rely on behavioral signs and parental report.
- Q: Can AN be diagnosed in preadolescents?
- A: Yes. The age of onset of AN has continued to decrease. If they present with weight preoccupation, pursuit of thinness, and other diagnostic criteria, their diagnosis is AN.

ANTHRAX

Andrew P. Steenhoff

BASICS

DESCRIPTION

Bacillus anthracis is a spore-forming, gram-positive rod that can cause acute infection (anthrax) in humans and animals.

EPIDEMIOLOGY

- Anthrax is primarily zoonotic. Most naturally acquired anthrax infections are cutaneous (95%). Inhalational (5%) and GI (<1%) forms are particularly rare.
- Prior to October 2001, only 18 cases of inhalational anthrax were reported in the United States during the 20th century.
- No human-to-human spread of inhalational anthrax has been reported.
- Rare cases of human-to-human transmission of cutaneous anthrax have been reported after direct contact with infected skin lesions.
- Anthrax has been used as an agent of bioterrorism.

GENERAL PREVENTION

- Antibiotics are effective against germinating *B. anthracis* but not against the spores. Therefore, if prophylactic antibiotics are stopped prematurely, remaining spores can cause disease when they germinate. This phenomenon of delayed-onset disease does not occur with cutaneous or GI exposures.
- Where the threat of transmission of *B. anthracis* spores is deemed credible, decontamination of skin and potential fomites (e.g., clothing) may be considered to reduce the risk for cutaneous and GI forms of the disease.
- Anthrax vaccine absorbed (AVA) is the only licensed human anthrax vaccine in the United States. Primary vaccination consists of subcutaneous injections at 0, 2, and 4 weeks and 3 booster vaccinations at 6, 12, and 18 months. Annual booster injections are required to maintain immunity. The most common adverse event is injection-site

discomfort (e.g., edema, pain, local hypersensitivity).

- Infection control
 - Immediately notify the hospital epidemiologist, infection control department, or local health department of suspected cases.
 - No data suggest that patient-to-patient transmission of inhalational anthrax occurs. Standard barrier isolation precautions are recommended for all hospitalized patients with all forms of anthrax infection. High-efficiency particulate air-filter masks or other measures for airborne precautions are not indicated.
 - There is no need to immunize or provide prophylaxis to patient contacts unless they, like the patient, were exposed to the aerosol.
 - If anthrax is used as a bioweapon, spores may be detected on environmental surfaces. Inhalational anthrax is unlikely to be caused by secondary aerosolization of these spores.

ALERT

Pulmonary disease caused by anthrax is a hemorrhagic mediastinitis with pleural effusions and not a bronchopneumonia.

PATHOPHYSIOLOGY

- After inhalation, wound inoculation, or ingestion, *B. anthracis* spores infect macrophages, germinate, and proliferate.
 - Proliferation occurs at the site of infection and in regional lymph nodes.
 - Replicating bacteria release toxins, leading to edema, hemorrhage, and necrosis.
- Incubation period depends on the route of transmission.
 - Inhalational anthrax: Infection requires inhalation of >8,000 spores; incubation period is 2–60 days.
 - Cutaneous anthrax: Spores enter a cut or abrasion in the skin; incubation period is 1–12 days.
 - GI anthrax: Spores are ingested in undercooked, infected meat; incubation period is 1–7 days; infection occurs in the upper (oropharyngeal lesions) or lower (intestinal lesions) GI tract.
- Hematogenous spread of the bacteria causes infection at other sites, including the CNS, liver, spleen, and kidney.

COMMONLY ASSOCIATED CONDITIONS

If anthrax is intentionally released, physicians must be alert for diseases caused by other potential biologic warfare agents (e.g., plague, tularemia, Q fever, smallpox, and botulism).

DIAGNOSIS

HISTORY

- Inhalational anthrax
 - Clinical presentation is a 2-stage illness.
 - Initial symptoms are nonspecific and last 1–3 days. They include low-grade fever, dry cough, headache, vomiting, chills, weakness, abdominal pain, and substernal discomfort. This stage may be followed by a brief period of apparent recovery.
 - 2nd-stage symptoms develop abruptly 2–5 days later: fever, hemoptysis, dyspnea, chest pain, and profuse diaphoresis. Death may occur within 1–2 days.
- Cutaneous anthrax
 - Painless lesions develop on affected areas soon after exposure.
 - Systemic symptoms of fever, malaise, and headache may occur.
- GI anthrax
 - Oropharyngeal form causes sore throat, dysphagia, and fever.
 - Intestinal form also causes nausea, vomiting, anorexia, severe abdominal pain, and bloody diarrhea.

PHYSICAL EXAM

- Clinical presentation of anthrax in children is varied; rapid diagnosis and effective treatment require recognition of the broad spectrum of clinical presentations.
- Inhalational anthrax
 - Tachypnea, hypoxia, cyanosis
 - Stridor, rales, signs of pleural effusion
 - Hemoptysis, hematemesis, melena
- Cutaneous anthrax
 - Initial painless, pruritic macule or papule enlarges into a 1–3-cm

round ulcer by the second day.

- 1–3-mm vesicles with clear or serosanguineous fluid surround the ulcer.
- A painless, depressed, black eschar follows, often with extensive local edema.
- Over 1–2 weeks, the eschar dries, loosens, and falls off, occasionally with scarring.
- Painful, regional lymphadenopathy may occur.
- GI anthrax
 - Unilateral oral or esophageal ulcers, cervical lymphadenopathy
 - Cecal or terminal ileal ulcers (Intestinal anthrax progresses to massive ascites and acute abdomen.)
- Disseminated anthrax (potential complication of any of the above forms of anthrax):
 - Sepsis syndrome: tachycardia, hypotension, septic shock
 - Meningitis: meningismus, delirium, obtundation

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Gram stain smear and culture from vesicular fluid
 - Diagnose cutaneous anthrax
 - Gram stain reveals large, gram-positive, boxcar-shaped bacilli.
 - Capsule is visible on polychrome methylene blue stain.
 - *B. anthracis* grows readily on blood agar.
- Anthraxin skin test
 - Measures anthrax cell-mediated immunity
 - It is positive in 80% of patients within 72 hours of infection and in >95% of cases within 3 weeks.
 - The test was positive in 72% of patients >16 years after recovery.
- Serologic enzyme-linked immunosorbent assay (ELISA):
 - Measures antibodies to the lethal and edema toxins of *B. anthracis*
 - Positive if a single acute-phase titer is >1:32 or if there is a 4-fold or greater rise between acute and convalescent titers collected 4 weeks apart
- Polymerase chain reaction, immunohistochemical staining
- Nasopharyngeal swab or induced respiratory secretion culture

- Used for epidemiologic investigation
- The sensitivity, specificity, and predictive value of nasal swab testing are unknown; therefore, this test should not be used to guide the use of postexposure prophylactic antibiotics.
- Blood culture: Patients with cutaneous anthrax may have bacteremia with *B. anthracis* even without significant signs of systemic disease.
- CBC
- Serum electrolytes, glucose, and calcium
 - Hypokalemia, acidosis, hypoglycemia, and hypocalcemia occurred during experimental anthrax infection in animals.
 - Hemorrhagic meningitis

Imaging

Chest x-ray (or chest CT scan)

- Inhalational anthrax causes a hemorrhagic mediastinitis.
- May show a widened mediastinum and pleural effusions
- No infiltrates are present.

DIFFERENTIAL DIAGNOSIS

- The prodromal illness of inhalational anthrax may resemble a lower respiratory tract infection, although upper respiratory infection symptoms are characteristically absent.
- Patients with inhalational anthrax may have a widened mediastinum on chest radiograph which may resemble an aortic aneurysm or bacterial mediastinitis.
- Necrotic skin lesions may resemble plague, tularemia, ecthyma gangrenosum, and brown recluse spider bite.
- GI anthrax may be confused with other infectious enteritides (e.g., *Shigella*, *Salmonella*, *Yersinia*, *Campylobacter*, enterohemorrhagic *Escherichia coli*, *Clostridium difficile*, colitis), intussusception, Meckel diverticulum, and inflammatory bowel disease.

TREATMENT

MEDICATION

- Postexposure prophylaxis

- Ciprofloxacin 15 mg/kg (up to 500 mg) or doxycycline 2.2 mg/kg (up to 100 mg) or levofloxacin 8 mg/kg (up to 250 mg) PO b.i.d. for 60 days.
- Pediatric: Use ciprofloxacin for initial prophylaxis. Switch to amoxicillin or penicillin if susceptibility testing permits.
- Treatment
 - For all forms of anthrax, begin with IV therapy and switch to oral therapy when clinically appropriate. Treat for 60 days (IV and PO combined).
 - Inhalational or GI anthrax: ciprofloxacin 15 mg/kg (up to 400 mg) or doxycycline 2.2 mg/kg (up to 100 mg) IV q12h plus clindamycin or rifampin
 - Cutaneous anthrax: ciprofloxacin or doxycycline IV. (Pediatric: Begin therapy with ciprofloxacin [plus clindamycin or rifampin for inhalational/GI anthrax] and convert to penicillin G IV if susceptibility testing permits and when clinical improvement is documented.)

GENERAL MEASURES

Direct physical contact with a substance alleged to be anthrax:

- Wash exposed skin and articles of clothing with soap and water.
- Administer postexposure prophylaxis until the substance is proved not to be anthrax.
- Contact the public health department or the Centers for Disease Control and Prevention (CDC).
- For severe anthrax, anthrax-specific hyperimmune globulin 5% should be considered in consultation with CDC.

ONGOING CARE

PROGNOSIS

- Inhalational anthrax
 - Case fatality rates were previously estimated to be >85% after symptoms develop. However, early use of appropriate antibiotic therapy appears to improve survival.

- Survival rate is higher if symptoms develop >30 days after exposure.
- Cutaneous anthrax
 - Case fatality rate is 20% without antibiotic treatment and <1% with antibiotic treatment.
- GI anthrax: Case fatality rate is 25–60%.

COMPLICATIONS

- Antibiotic therapy of cutaneous anthrax limits the likelihood of developing systemic symptoms but does not change the course of the eschar formation.
- Systemic dissemination of inhalational, cutaneous, or GI anthrax may lead to sepsis, meningitis, and death.

CODES

ICD10

- A22.9 Anthrax, unspecified
- A22.0 Cutaneous anthrax
- A22.1 Pulmonary anthrax

FAQ

- Q: Does the government have a plan in place if there were mass exposure to anthrax?
- A: Yes. Under emergency plans, the federal government would ship appropriate antibiotics from its stockpile to wherever they are needed.
- Q: Should individuals ask their physicians to write a prescription for ciprofloxacin (or other antibiotic) so they have prophylaxis available?
- A: No. Ciprofloxacin and other antibiotics should not be prescribed unless there is a clearly indicated need. In addition, indiscriminate prescribing and widespread use of ciprofloxacin could hasten the development of drug-resistant organisms.
- Q: Can a person get screened or tested for anthrax?
- A: No screening test is available to determine whether anthrax exposure has occurred. The only way exposure can be determined is through a public health investigation.
- Q: What are the clues to differentiate pulmonary or inhalational anthrax from RSV in children?
- A: Children with pulmonary anthrax display a high WBC count with

left shift compared to the relatively normal WBC of those with RSV.
Blood O₂ levels may be severely depressed in inhalational anthrax.

APLASTIC ANEMIA

Craig M. Forester • James N. Huang

BASICS

DESCRIPTION

Aplastic anemia represents a heterogeneous group of disorders characterized by peripheral pancytopenia and bone marrow hypocellularity.

EPIDEMIOLOGY

Incidence

- Estimated incidence of 2:1,000,000 per year in Western Hemisphere and Europe with increased incidence of 5–7:1,000,000 per year in Far East and those of Asian descent
- In the pediatric population, most commonly presents between ages 15 and 25 years

RISK FACTORS

Genetics

Patients with a number of inherited bone marrow failure syndromes are at increased risk of developing aplastic anemia, but there is no known genetic mutation associated with acquired aplastic anemia.

GENERAL PREVENTION

There are no preventive measures for acquired aplastic anemia.

PATHOPHYSIOLOGY

- Most instances of acquired aplastic anemia are thought to occur through a T-cell dependent autoimmune process leading to apoptosis of hematopoietic stem or progenitor cells.
- Additionally, exposure to certain toxins, chemicals, medications (classically chloramphenicol), and high doses of radiation can also lead to marrow aplasia.

ETIOLOGY

- Acquired
 - Idiopathic (70% of cases)
 - Toxin: exposure to arsenic, benzene, radiation, organophosphates, organochlorines
 - Drugs: chloramphenicol, numerous chemotherapeutic agents
 - Radiation
 - Paroxysmal nocturnal hemoglobinuria (PNH)
 - Seronegative hepatitis (non-A, non-B, and non-C)
 - HIV-1, Epstein-Barr virus (EBV), human herpes virus-6, cytomegalovirus (CMV)
 - Malnutrition
 - Pregnancy

COMMONLY ASSOCIATED CONDITIONS

- Congenital or inherited bone marrow failure syndromes
 - Fanconi anemia, Shwachman-Diamond syndrome, Diamond-Blackfan anemia, dyskeratosis congenita, congenital amegakaryocytic thrombocytopenia, Pearson syndrome
- Acquired
 - Differentiating aplastic anemia from refractory cytopenia of childhood (RCC), defined by thrombocytopenia/neutropenia with impaired maturation of erythroid lineage and increased proerythroblasts in bone marrow, is crucial.
 - Differentiating RCC from aplastic anemia can be difficult but important as RCC should be considered a form of myelodysplastic syndrome (MDS) and evaluated for hematopoietic stem cell transplantation (HSCT).

DIAGNOSIS

HISTORY

- Detailed history including birth history, growth trajectory, antecedent illnesses, infections, environmental exposures
- Comprehensive review of systems with emphasis on neurologic (including developmental delay and learning disabilities),

dermatologic, cardiac, pulmonary, endocrine (hypogonadism, growth delay), and hematologic systems

- Family history of cancer predisposition, excessive toxicity to chemotherapy, unexplained fetal loss, anemia/cytopenias, or congenital anomalies

PHYSICAL EXAM

- Thorough physical exam combined with plotting of growth curves
- Head: evaluate for eye, epicanthal folds, jaw, palate abnormalities, oral mucosal lesions/bleeding, thrush
- Cardiopulmonary: auscultation for cardiac anomalies, dyspnea, diminished aeration, asymmetry
- GI: hepatosplenomegaly, palpation for masses
- GU: renal/urinary/ureter abnormalities, gonadal abnormalities, or undescended testes
- Skeletal: dysmorphisms, forearms, thumbs, vertebral anomalies, osteopenia
- Skin: pigmentation changes, eczematous rash, nail abnormalities, bruising, petechiae, pallor
- Lymphadenopathy

DIAGNOSTIC TESTS & INTERPRETATION

Lab

To confirm the diagnosis:

- Diagnosis requires exclusion of other disease processes associated with pancytopenia (see “[Etiology](#)” and “[Differential Diagnosis](#)” sections) as well as the following:
 - Empty or hypoplastic bone marrow
 - 2 out of 3 of the following: absolute neutrophil count (ANC) $<1,500 \times 10^6/L$, platelets $<50,000 \times 10^6/L$, hemoglobin (Hgb) $<10 \text{ g/dL}$
- Severe aplastic anemia (sAA)
 - Bone marrow cellularity $<25\%$
 - 2 out of 3 of the following: ANC $<500 \times 10^6/L$, platelets $<20,000 \times 10^6/L$, absolute reticulocyte count $<20 \times 10^9/L$
- Very severe aplastic anemia: the criteria are the same as for sAA, except for ANC $<200 \times 10^6/L$.

To exclude other causes:

- Complete blood count, + reticulocyte count
- Peripheral blood smear
- Hgb F %
- Liver function tests, lactate dehydrogenase (LDH), uric acid
- Direct and indirect Coombs assay
- Baseline serum iron, ferritin, total iron-binding capacity (TIBC)
- Flow cytometry for glycosylphosphatidylinositol (GPI)-anchored proteins CD55/CD59
- Vitamin B₁₂, folate, copper levels
- Viral studies: hepatitis A, B, and C; EBV, CMV, HIV, human herpesvirus 6 (HHV-6), varicella-zoster virus (VZV), parvovirus
- Antinuclear antibody (ANA), anti-double stranded DNA (dsDNA)
- Acid-fast bacillus (AFB) staining of bone marrow aspirate
- Human leukocyte antigen (HLA) typing of patient and family members
- Ruling out inherited bone marrow failure syndromes:
 - Chromosomal breakage (mitomycin C or diepoxybutane): Fanconi anemia
 - Telomere length: dyskeratosis congenita
 - Exocrine pancreatic testing: serum trypsinogen and pancreatic isoamylase: Shwachman-Diamond syndrome
 - Erythrocyte adenosine deaminase: Diamond-Blackfan anemia
 - c-MPL mutation: congenital amegakaryocytic thrombocytopenia

Imaging

- Chest x-ray
- Abdominal ultrasound (US)
- Echocardiogram

Diagnostic Procedures/Other

- Bone marrow aspirate and biopsy
- Cytogenetics of bone marrow with fluorescence in situ hybridization (FISH) for monosomy 5, 7, 8

Pathologic Findings

Bone marrow fragments are hypocellular with prominent fat spaces and reduced erythropoiesis, megakaryocytes, and granulocytes. Lymphocytes,

macrophages, plasma cells, or mast cells may be prominent. Appearance of dysplasia in megakaryocyte or granulocytic lineage, blasts, hypercellularity, or increased reticulin staining are not consistent with aplastic anemia.

DIFFERENTIAL DIAGNOSIS

- Myelosuppression secondary to ongoing infection (viral, tuberculosis)
- MDS (including RCC)
- Hematologic malignancy
- Nutritional deficiency: vitamin, mineral, or starvation/anorexia
- Autoimmune disease: systemic lupus erythematosus (SLE), thyroid disease, rheumatoid arthritis
- PNH
- Metastatic disease
- Hemophagocytic histiocytosis

TREATMENT

Treatment for aplastic anemia that does not meet the severe or very severe criteria is individualized and controversial as some patients do spontaneously improve. However, patients with severe or very severe aplastic anemia should be promptly treated because of their high risk of infection.

MEDICATION

First Line

In all patients with sAA who are younger than the age of 40 years and without significant comorbidities, the treatment of choice is HSCT with a matched sibling donor (MSD). Superior and durable outcomes for MSD transplants conditioned with cyclophosphamide/antithymocyte globulin (ATG) as 1st-line therapy stresses importance of timely workup and HLA typing.

Second Line

For patients without an MSD or with significant comorbidities:

- Immunosuppressive therapy (IST) with combination horse ATG and

cyclosporine (ATG/CsA) followed by prolonged taper of cyclosporine.

- If patients do not show clinical improvement within 3–6 months, consider an alternative donor HSCT such as with a matched unrelated donor (MUD) HSCT, if available, or repeat trial of IST.

Supportive Therapy:

Patients should be transfused when symptomatic with leukocyte-reduced, irradiated PRBCs and platelets. Transfusions are weighed against the risk of alloimmunization and graft rejection with allogeneic bone marrow transplant (BMT), but most institutions will transfuse to keep Hgb >7–8 g/dL and platelets above 10,000/mm³. Transfusions should be with CMV-negative blood (if patient is CMV seronegative) if patient is likely to undergo transplant.

ISSUES FOR REFERRAL

Pediatric hematology/oncology/BMT: As a rare disorder, patients are typically managed by centers with hematologic experience and transplant capabilities.

ADDITIONAL THERAPIES

- Use of *Pneumocystis carinii* (jiroveci) pneumonia (PCP) prophylaxis prior to BMT is institution-dependent but some recommend use of pentamidine (with atovaquone or dapsone as second line), avoiding sulfamethoxazole/trimethoprim due to its myelosuppressive properties.
- Antifungal prophylaxis is also used by many institutions.
- Granulocyte colony-stimulating factor (G-CSF) support may be used in setting of acute infection but has not been shown to improve overall survival or remission rates.
- Supportive care, androgens, cyclosporine, or growth factors alone are not definitive therapies. Corticosteroids alone are also not proven to be effective and lead to increased susceptibility to fungal infections.

INPATIENT CONSIDERATIONS

Initial Stabilization

- Patients should be transfused slowly initially with PRBC 5 cc/kg over 4 hours to avoid pulmonary overcirculation.
- Platelet transfusions for symptomatic bleeding

- Cultures of blood and urine should be obtained with all fevers, and empiric broad-spectrum antibiotics coverage should be started while awaiting culture results.

Admission Criteria

Symptomatic anemia, fever, severe thrombocytopenia, or any evidence of clinical bleeding must be admitted for supportive care and monitoring.

IV Fluids

Unless the patient has had a recent history of inadequate intake or losses, IV fluids are not usually necessary at the outset. Bear in mind that the patient will likely be receiving additional volume due to transfusions.

Nursing

Patients should be roomed in isolation if possible.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Regardless of whether IST or BMT is chosen for treatment modality, follow-up should be lifelong given risk of recurrence of aplastic anemia or transformation to MDS or malignancy. Long-term retrospective studies have demonstrated rates of relapse of up to 38%, with incidence of clonal transformation in 10–25% of patients who undergo IST.

Patient Monitoring

Those who undergo HSCT are expected to have hematopoietic reconstitution as they engraft. Hematologic recovery in those who undergo IST may take several months: 90% of patients who respond will do so by 3 months, but some patients may take up to 6 months from ATG to recover marrow function.

Parameters of Recovery

- Improve overall hematopoiesis to reduce transfusion dependency and no longer fulfill criteria for sAA by 6 months. Neutrophil recovery may be the first cytopenia to improve.
- Relapse or clonal evolution commonly occurs at 2–4 years from time of IST. Some centers recommend monitoring bone marrow aspirates

with biopsy at 6-month intervals for 1st year after IST, then annually.

PATIENT EDUCATION

- NIH site: <http://www.nhlbi.nih.gov/health/health-topics/topics/aplastic/>
- Aplastic Anemia & MDS International Foundation:
<http://www.aamds.org/about/aplastic-anemia>

DIET

Recommend low bacterial content diet.

PROGNOSIS

- Aplastic anemia has a high rate of mortality if left untreated. Death is predominantly from infection and hemorrhage. If patients are treated with antibiotics and transfusions alone, mortality is 80% in 2 years.
- First line
 - MSD: HSCT with MSD from bone marrow source has a predicted 6-year outcome of 80–91% in children younger than 20 years of age.
- Second line
 - IST: Response rate of IST in children is 75%.
- Relapse/salvage: aplastic anemia refractory to IST at 6 months should be considered for salvage therapy: MUD-HSCT for younger patients; repeat IST for older patients and those with significant comorbidities.
- MUD: Recent trials have shown improved survival of >60% and as high as 94% in children who have undergone MUD-HSCT for sAA.
- Repeat IST: Patients refractory to the initial course of IST had a response rate of 30–40% at 6 months to ATG/CsA.

COMPLICATIONS

- Infection
- Hemorrhage
- Iron overload requiring phlebotomy or chelation therapy
- Allosensitization to transfusion products

CODES

ICD10

- D61.9 Aplastic anemia, unspecified
- D61.89 Oth aplastic anemias and other bone marrow failure syndromes
- D61.3 Idiopathic aplastic anemia

FAQ

- Q: When starting IST, should I choose horse ATG or rabbit ATG as part of the ATG/cyclosporine/prednisone regimen?
- A: A head to head comparison of horse ATG (hATG) versus rabbit ATG (rATG) in immunosuppressive regimens showed inferiority of rATG in 1st-time treatment for sAA (Scheinberg, NEJM 2011).
- Q: When should patient and family members be HLA typed when considering aplastic anemia?
- A: HLA typing should be performed on patient and family members once peripheral pancytopenia and bone marrow hypocellularity is confirmed.
- Q: What are common side effects of the IST regimen?

- A: ATG may cause hypersensitivity reactions, whereas cyclosporine A may cause hypertension, electrolyte abnormalities, nephropathy, and hirsutism.

APPARENT LIFE-THREATENING EVENT

Craig DeWolfe

BASICS

DESCRIPTION

- Apparent life-threatening event (ALTE) is an episode that is frightening to the observer and is characterized by some combination of the following:
 - Apnea: central or occasionally obstructive
 - Color change: usually cyanotic or pallid but occasionally erythematous or plethoric
 - Marked change in muscle tone: usually limp
 - Choking or gagging
- ALTE describes a presentation rather than a diagnosis and should therefore trigger a pursuit of an etiology.

EPIDEMIOLOGY

- 43% of healthy term infants have at least one 20-second apneic episode over a 3-month period.
- 5.3% of parents recall seeing apnea.
- 0.2–0.9% of infants have an episode of apnea that results in an admission to the hospital.

RISK FACTORS

- Preterm infants born less than 34 weeks post–conceptual age have higher rates of apnea.
 - Differences resolve by 43 weeks post–conceptual age.
- Prematurity, multiple ALTEs, and suspected child maltreatment confer a greater risk for a future adverse event and/or serious underlying diagnosis.

PATHOPHYSIOLOGY

- No unifying pathophysiology because of the numerous potential presentations and underlying diagnoses

- Central apnea: disrupted propagation of respiratory signals from the brainstem along the descending neuromuscular pathways. Examples include the following:
 - Head trauma
 - Congenital central hypoventilation syndrome
- Obstructive apnea: neuromuscular respiratory effort disrupted by an occluded airway. Examples include the following:
 - Upper respiratory infection
 - Pierre Robin
- Mixed apnea: combination of central and obstructive apnea. Examples include the following:
 - Laryngomalacia with a sedating ingestion
 - Prematurity with superimposed viral infection
- Color change from decreased oxygenation or differential blood flow. Examples include the following:
 - Cyanotic heart disease
 - Acrocyanosis
- Altered muscle tone from central or autonomic nervous system disruption. Examples include the following:
 - Seizure
 - Breath-holding spell
- Choking or gagging: protective response to a stimulation of the airway

DIAGNOSIS

ALERT

ALTE is a symptom complex rather than a diagnosis. The practitioner should therefore attempt to identify an underlying diagnosis to explain the presentation.

HISTORY

A full, uninterrupted description of the event by a witness may answer or prompt the need to explore the following features:

- Presence of apnea

- Type suggests different causes.
 - Obstructive symptoms
 - Central symptoms
- Duration may suggest severity: <20-second central apnea is physiologic if not associated with other symptoms such as cyanosis.
- Presence of color change and distribution
 - Perioral and peripheral cyanosis are not suggestive of hypoxia unless accompanied by central cyanosis.
 - Blue/purple discoloration of face, lips, or core body indicates central cyanosis.
- Change in tone, rhythmic shaking, and/or eye deviation may suggest a seizure.
- Relationship to feeds and/or milk in the mouth may suggest aspiration.
- Fatigue or diaphoresis with feeds may suggest a cardiac condition.
- Coryza may suggest an upper or lower respiratory infection.
- Fever may suggest an infectious etiology.
- History of trauma may suggest an intracranial bleed.
- State of alertness prior to ALTE may suggest sleep apnea.
- Discrepancies among witnesses may suggest nonaccidental trauma.
- Type of resuscitation needed may provide a sense of severity or an opportunity for anticipatory guidance.
- Current condition of child and/or time required to reach baseline: may suggest an ongoing, evolving condition and/or postictal period
- Location of event and position of child (i.e., supine/prone)
- Medications dosed or taken by a breastfeeding mother
- Prematurity
- Prior history of ALTE
- Family history of ALTE, SIDS, or sudden unexpected death

PHYSICAL EXAM

- Ongoing abnormal symptoms may suggest an evolving and/or underlying condition and should be approached differently than if the patient had a normal exam.
 - Arousal
 - Vital signs
 - Signs of trauma

- Irritability
- Full fontanelle
- Pupil reactivity, conjunctival/retinal hemorrhage
- Bruising or bleeding
- Persisting signs of disordered breathing
- Heart rhythm/murmurs suggestive of an arrhythmia or cyanotic heart disease
- Neurologic exam
- Consider observing a feeding.

ALERT

Recurrent ALTEs; historical discrepancies; a family history of ALTE, SIDS, or unexplained death; parents calling emergency services; unexplained facial bruising or bleeding; and the presence or irritability at the time of presentation would warrant a thorough assessment for possible child maltreatment.

DIAGNOSTIC TESTS & INTERPRETATION

- Routine testing is unlikely to be helpful in patients who are well-appearing and have no other findings suggestive of a particular diagnosis.
- In addition to discomfort, inconvenience, risk, and costs of various tests, an indiscriminate number of screening tests may affect the reliability of the results and initiate an inappropriate and unnecessary testing cascade.

Lab

- If indicated by the history and/or physical
 - Basic metabolic panel
 - Blood culture
 - Cerebral spinal fluid analysis +/- culture
 - Complete blood count
 - Lactate level
 - Newborn metabolic screen
 - Urine analysis +/- culture
 - Venous blood gas
 - Viral studies

Imaging

- If indicated by the history and/or physical
 - Airway imaging
 - Contrast study of the gastrointestinal tract
 - Chest x-ray
 - Head CT
 - Isotope-labeled milk scan

Additional Testing

- In one study, even though 89% of patients presenting with ALTE had radiographic evidence of GER, half had another diagnosis that was thought to be more consistent with the presentation.
- If indicated by the history and/or physical
 - Airway visualization
 - Dilated fundoscopic examination
 - Electrocardiography
 - Electroencephalography
 - Four-extremity blood pressure
 - pH probe
 - Sleep study

DIFFERENTIAL DIAGNOSIS

Estimated frequency of the involved system given as a percentage

- Gastrointestinal: 34%
 - Colic
 - Dysphagia
 - Esophageal dysfunction
 - Gastroenteritis
 - GER
 - Surgical abdomen
- Neurologic: 17%
 - Apnea of prematurity
 - Brain tumor
 - Central hypoventilation syndrome (Ondine's curse)
 - Congenital malformation of the brainstem
 - Head injury (intraventricular hemorrhage, subarachnoid

- hemorrhage)
- Hydrocephalus
- Meningitis/encephalitis
- Neuromuscular disorders
- Seizure
- Vasovagal reaction
- Respiratory: 11%
 - Aspiration pneumonia
 - Foreign body
 - Other lower or upper respiratory tract infection
 - Reactive airway disease
 - Respiratory syncytial virus
 - Pertussis
- Otolaryngologic: 4%
 - Laryngomalacia or tracheomalacia
 - Anatomic airway stenosis or obstruction
 - Obstructive sleep apnea
- Child maltreatment syndrome: 1–2%
 - Intentional suffocation
 - Munchausen syndrome by proxy
 - Shaken baby syndrome
 - Head injury
 - Ingestion
- Cardiovascular: 1%
 - Cardiac arrhythmia/prolonged QTc
 - Cardiomyopathy
 - Congenital heart disease
 - Myocarditis
- Metabolic/endocrine: 1%
 - Electrolyte disturbance
 - Hypoglycemia
 - Inborn error of metabolism
- Other infections: 2%
 - Sepsis
 - Urinary tract infections

- Other: 6%
 - Anemia
 - Breath-holding spell
 - Choking
 - Drug or toxin reaction
 - Hypothermia
 - Physiologic event (periodic breathing, acrocyanosis)
 - Unintentional smothering
- Idiopathic/apnea of infancy: 23%

TREATMENT

INPATIENT CONSIDERATIONS

- Hospital admission is not necessary if the patient is well-appearing and has a self-limited diagnosis to explain the presentation. Admission criteria would include the following:
 - Premature patients less than 45 weeks post-gestational age
 - Patients with clusters or multiple episodes of ALTE
 - Suspected child maltreatment
- If admitted, place on a cardiorespiratory monitor with pulse oximetry.
- Manage patients with persistent symptoms based on the underlying working diagnosis.

ONGOING CARE

- All patients should be offered the following anticipatory guidance:
 - Safe sleep practices and other SIDS prevention techniques
 - CPR overview

FOLLOW-UP RECOMMENDATIONS

Return to medical attention for recurrence.

PROGNOSIS

- Studies on morbidity and mortality are generally incomplete and often contradictory. Differences in reported prognoses from such studies

may reflect differences in study design (e.g., patient inclusion criteria, definitions, and follow-up periods, etc.).

- Studies report mortality between 0 and 6%.
- Insufficient data to quantify risk of subsequent event or underlying diagnosis in the asymptomatic patient
- No developmental repercussions among patients who are discharged without a serious underlying diagnosis and have no subsequent events

ADDITIONAL READING

CODES

ICD10

- R68.13 Apparent life threatening event in infant (ALTE)
- P28.4 Other apnea of newborn
- R23.0 Cyanosis

FAQ

- Q: What is the relationship between ALTE and SIDS?
- A: There is no established relationship between ALTE and SIDS. The use of the terms “near-miss SIDS” and “aborted crib death” are discouraged. 4–13% of patients diagnosed with SIDS had a preceding

history of apnea, a percentage only slightly higher than healthy controls. The “back to sleep” campaign, which has dramatically decreased the SIDS rate, has had no effect on ALTE presentations.

- Q: What is the role of home monitoring in ALTE?
- A: Home monitors are not efficacious in preventing mortality among patients with ALTE. In fact, there is evidence that caregivers may have increased anxiety, depression, and hostility, whereas patients may have worse developmental consequences. The American Academy of Pediatrics suggests that home monitors may have a role in certain situations such as a known unstable airway, abnormal respiratory control, or symptomatic and technologically dependent chronic lung disease.
- Q: Why aren't there established guidelines with respect to the evaluation and management of patients presenting with ALTE?
- A: No study has compared diagnostic or treatment strategies among first presenters with a sample size large enough to detect rare events in a prospective fashion. Future study of ALTE would be enhanced by applying definitions that could distinguish patient populations.

APPENDICITIS

Nora M. Fullington • Michael P. Hirsh

BASICS

DESCRIPTION

Acute inflammation or infection of the vermiform appendix

EPIDEMIOLOGY

- Most common surgical emergency of childhood
- Affects 5 of 100,000 persons in the United States
- 293,000 admissions in the United States in 2010
- 80,000 pediatric cases per year in United States
- Most commonly seen in ages 5–40 years, with peak age of incidence age 28 years

PATHOPHYSIOLOGY

- Acute inflammation of the appendiceal lumen is caused by obstruction (i.e., by a fecalith, calculi, parasites, hyperplastic lymphoid tissue, or tumor).
- Appendix is innervated by somatic afferent nerves of the 10th dermatome overlying the epigastrium and periumbilical areas.
- In the first phase of pain, occlusion causing increasing wall tension results in vague pain poorly referred to this area.
- Increasing wall tension and full-thickness serositis results in inflammation of surrounding tissues, and the second phase of pain is localized to the area in which the appendix is lying.
- In 85% of patients, this is at McBurney point, but pelvic, retrocecal, retroperitoneal, inguinoscrotal, or other orientations will result in variance of location and intensity of this pain.

DIAGNOSIS

Classic signs and symptoms include right lower quadrant pain, anorexia, nausea and vomiting, and fever.

HISTORY

- Abdominal pain is most common symptom.
- Pain usually begins in the periumbilical or epigastric regions prior to migrating to the right lower quadrant. Pain is followed by nausea and vomiting with fever.
- Leukocytosis occurs later.
- Timing of pain preceding nausea and vomiting and absence of diarrhea in most cases are distinguishing factors from gastroenteritis.
- Anorexia is present in the majority of cases but may not be a prominent symptom if the appendix is retrocecal or retroperitoneal.
- Perforation of the inflamed appendix may result in temporary relief of pain. These patients can proceed to develop distension, dehydration, diarrhea from perirectal irritation, and dysuria from perivesicular irritation.
- Delayed diagnosis and perforation occur more frequently in young children, presumably because they are less able to articulate their symptoms.

PHYSICAL EXAM

- Low-grade fever is common unless perforation has already occurred.
- Perforation can result in worsened fever, tachypnea, and tachycardia.
- Pain and tenderness at McBurney point (1/3 the distance from the anterior superior iliac spine [ASIS] in a line from the umbilicus to the ASIS)
- Findings may include abdominal rebound tenderness, guarding, and focal tenderness on rectal exam.
- Other signs:
 - Rovsing sign is pain in the right lower quadrant with palpation in the left lower quadrant.
 - Psoas sign is pain in the right lower quadrant with passive right hip extension and may be associated with a retrocecal appendix.
 - Obturator sign is pain in right lower quadrant with right hip and knee flexion followed by internal rotation and may be associated with a pelvic appendix.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- CBC, expect elevated WBC count (10,000–17,000 cells per μL range) with left shift
- Erythrocyte sedimentation rate is usually normal.
- C-reactive protein can be elevated but is nonspecific.

Imaging

Diagnosis can often be made with history, physical exam, and laboratory studies without imaging with a diagnostic accuracy of 80–90% in some studies.

- Abdominal radiograph
 - Often normal
 - May show fecalith, indistinct psoas margins, cecal wall thickening
 - Free air or pneumoperitoneum may indicate a perforation.
- Ultrasound
 - Currently considered the initial imaging study of choice for the diagnosis of appendicitis
 - Findings include edema, inflammation, or abscess formation.
 - Most specific finding is an appendiceal maximum outer diameter (MOD) of ≥ 7 mm (associated with a sensitivity of 98.7% and a specificity of 95.4% for the diagnosis).
- CT scan
 - Has a high diagnostic accuracy for appendicitis and may have a higher sensitivity than ultrasound; however, requires exposure to ionizing radiation and may be avoidable with careful history and physical exam, use of labs, and less invasive imaging
 - Findings include fat stranding, abscess or phlegmon, appendicolith when present, and focal cecal thickening.

DIFFERENTIAL DIAGNOSIS

- Infection
 - Gastroenteritis (e.g., *Yersinia*, *Campylobacter*)
 - Constipation
 - Right lower lobe pneumonia
 - Mesenteric adenitis
 - Typhlitis

- Urinary tract infection
- Pelvic inflammatory disease, tubo-ovarian abscess, or ectopic pregnancy
- Parasitic infection (*Trichuris trichiura*, *Ascaris lumbricoides*)
- Inflammatory
 - Inflammatory bowel disease
 - Anaphylactic purpura
 - Cholecystitis
 - Pancreatitis
 - Diverticulitis
- Genetic/metabolic
 - Diabetes
 - Sickle cell disease
 - Renal stones
 - Hyponatremia
 - Crohn disease
- Miscellaneous
 - Functional abdominal pain
 - Torsion of testes or ovaries
 - Ovarian cyst
 - Endometriosis
 - Small bowel obstruction

TREATMENT

GENERAL MEASURES

- IV fluids to correct hypovolemia, electrolyte abnormalities
- Broad-spectrum antibiotics
- Pain medications

SURGERY/OTHER PROCEDURES

- Emergency appendectomy
 - Laparoscopic technique is now practiced by most surgeons in the United States.
 - It shows comparable results to open technique, allows wider

exploration, and is associated with faster recovery in adults to daily activity.

- Laparoscopic approaches now include single-port technology that limit the incision to the umbilical location.
- Given the relative risk and delay of care with CT prep, there is some evidence that immediate surgery may be preferential to radiologic investigation.
- Perforated appendicitis
 - Can also be treated via a laparoscopic approach and use of suction/irrigation devices to cleanse the abdomen of collections.
 - In many patients with perforated appendicitis, nonoperative management with percutaneous abscess drainage and broad-spectrum antibiotics followed by interval appendectomy may be preferable.

ONGOING CARE

PROGNOSIS

- Recovery is rapid.
- Prognosis is excellent.
- Overall current survival rate in United States is 98%.
- It is estimated that 35,000 people die yearly from appendicitis worldwide.

COMPLICATIONS

- Rate of wound complication post laparoscopic appendectomy is 3.1%.
- Rate of abscess formation post appendectomy is 0–4% for nonperforated appendicitis and 14–20% for perforated appendicitis.
- Perforated appendicitis may result in greater risk of postoperative ileus and small bowel obstruction or fertility issues longer term.

CODES

ICD10

- K37 Unspecified appendicitis
- K35.80 Unspecified acute appendicitis
- K35.89 Other acute appendicitis

FAQ

- Q: What were historical milestones in the treatment of appendicitis?
- A: In 1735, Dr. Claudius Amyand performed an appendectomy in a situation of an appendicitis within a right inguinal hernia (this is now referred to as Amyand hernia). In 1886, Dr. Reginald Heber Fitz first described what we recognize as appendicitis in his treatise “Diseases of the Vermiform Appendix.” In 1887, Dr. Thomas Morton performed the first successful appendectomy under ether anesthesia. In 1889, Dr. Charles McBurney described the localization of pain from appendicitis.

ARTHRITIS, JUVENILE IDIOPATHIC (RHEUMATOID)

Elizabeth Candell Chalom

BASICS

DESCRIPTION

Chronic synovial inflammation of unknown etiology in at least 1 joint, for at least 6 weeks. Age of onset must be <16 years old.

Juvenile idiopathic arthritis (JIA) is classified as one of 7 subtypes:

- Oligoarticular arthritis affects <5 joints during the first 6 months of the disease. Tends to involve large joints, especially the knee. Peak age of onset is 1–6 years; 80% are antinuclear antibody (ANA)-positive:
 - Persistent oligoarticular JIA remains in <5 joints.
 - Extended oligoarticular JIA spreads to involve 5 or more joints. Has worse prognosis than persistent oligoarthritis.
- Polyarticular juvenile idiopathic arthritis affects ≥ 5 joints. Can occur at any age: Peak ages of onset are 1–4 years and 7–10 years.
 - Rheumatoid factor–positive (RF+) polyarticular juvenile idiopathic arthritis is like adult-onset idiopathic arthritis that occurs in a child. Often quite aggressive
 - Rheumatoid factor–negative (RF–) polyarticular juvenile idiopathic arthritis is usually less aggressive and easier to control.
- Systemic-onset idiopathic juvenile arthritis
 - Characterized by high, spiking quotidian or diquotidian fevers and an evanescent pink/salmon-colored macular rash
 - Affected children may also have lymphadenopathy, hepatosplenomegaly, pericarditis, or pleuritis.
 - Arthritis may not appear until weeks to months after the onset of the systemic symptoms.
 - Can occur at any age
- Enthesitis-related arthritis (ERA)
 - Enteses (e.g., osteotendinous junctions, osteoligamentous junctions) are sites where tendons or ligaments attach to bone.

- ERA generally affects boys in late childhood or adolescence.
- Many are human leukocyte antigen-B27–positive.
- Psoriatic arthritis is associated with psoriasis. It often begins in a few joints and then becomes polyarticular. It often involves small joints of hands and feet, as well as knees. Dactylitis is seen in nearly 50% of patients.

EPIDEMIOLOGY

Incidence

- Incidence ranges from 1 to 22/100,000/year.
- Affects ~70,000–100,000 children in the United States

Prevalence

- Prevalence ranges from 8 to 150/100,000; varies, but is thought to be ~1/1,000
- Girls are affected twice as often as boys, but boys are affected more frequently with ERA.
- ~50% of children with JIA have the oligoarticular type.
- 30% have the polyarticular type.
- 10% have systemic-onset JIA.

RISK FACTORS

Genetics

- Rare in siblings, but many studies have demonstrated increased frequencies of various human leukocyte antigen markers in JIA.
- Each marker may be associated with a different subtype of JIA:
 - Human leukocyte antigen-DR4: RF+ polyarticular JIA
 - Human leukocyte antigen-DR1: oligoarticular disease without uveitis
 - Human leukocyte antigen-DR5: oligoarticular JIA with uveitis
 - Human leukocyte antigen-B27: ERA
 - Human leukocyte antigen-A2: early-onset oligoarticular JIA

DIAGNOSIS

HISTORY

- Morning stiffness that improves after a warm shower/bath or with stretching and mild exercise is common in JIA. Many young children do not complain of pain, but walk with a limp or refuse to walk down stairs in the morning.
- Joints often become sore/painful again in the late afternoon or evening.
- Patients with JIA generally do not complain of severe pain, but rather they avoid using joints that are particularly affected.
 - If a child has severe pain in a joint, especially pain that seems out of proportion to the physical findings, diagnoses other than JIA should be entertained.
- In systemic JIA, the fever curve is important to document.
 - Between fever spikes, the child is often completely afebrile.
 - The rash is evanescent and patients often have a history of fatigue, malaise, and weight loss.

PHYSICAL EXAM

- Arthritis must be present, not just arthralgias:
 - In addition to swelling, warmth, and tenderness, there may be restricted range of motion in the affected joints and soft tissue contractures.
- Enthesitis and sacroiliac tenderness are often seen in ERA.
- In systemic JIA, the rash, if present, is very suggestive of this disease.
- Lymphadenopathy and hepatosplenomegaly may be seen in systemic JIA.
- A careful cardiac and pulmonary examination must be done to look for pericarditis and pleuritis.

ALERT

Arthritis must be present for at least 6 weeks before a patient can be diagnosed with JIA. Many viral illnesses can produce joint pain and swelling that mimics JIA, but resolves within 4–6 weeks.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- No laboratory finding is diagnostic for JIA.
- Many patients with JIA, especially the polyarticular and systemic types, have elevated sedimentation rates and anemia.

- Antinuclear antibody is a useful test in classifying patients with JIA and determining the risk of uveitis. Positive in the following:
 - 80% of oligoarticular
 - 40–60% of polyarticular
 - 15–20% of normal population
- Rheumatoid factor will be positive in 15–20% of patients with polyarticular arthritis and usually indicates a more aggressive form of arthritis.

Imaging

- Radiography is often normal early in JIA.
- Later, if arthritis persists, bone demineralization, loss of articular cartilage, erosions, and joint fusion may be seen.

DIFFERENTIAL DIAGNOSIS

- Monoarticular JIA
 - Septic joint
 - Toxic synovitis
 - Trauma
 - Hemarthrosis
 - Villonodular synovitis
- Monoarticular or oligoarticular JIA
 - Lyme disease
 - Acute rheumatic fever or poststreptococcal arthritis
 - Viral/postviral arthritis
 - Malignancies
 - Sarcoidosis
 - Inflammatory bowel disease
- Polyarticular JIA
 - Viral or postviral illness (especially parvovirus)
 - Lyme disease
 - Lupus
- Systemic-onset JIA
 - Infection
 - Oncologic process (leukemia, lymphoma)
 - Inflammatory bowel disease

- Lupus

TREATMENT

MEDICATION

First Line

- Steroids (glucocorticoids):
 - Intra-articular steroids: Triamcinolone hexacetonide injections are often used when patients have only 1 or 2 active joints.
 - Systemic steroids
 - Systemic steroids are often needed to control flares or with the initial presentation of polyarticular or systemic JIA. Because of the many side effects, patients should be weaned off steroids as soon as possible.
 - Glucocorticoids can be given orally (daily or every other day) or as IV pulses (every 1–8 weeks).
- NSAIDs
 - 1st-line therapy for mild JIA
 - If there is no response to the initial NSAID after 4–6 weeks of an adequate dose, a different one should be tried. Patients will often respond differently to the various NSAIDs.
 - If patients experience GI upset or excessive bruising, COX-2 inhibitors may be used. If arthritis remains active after 2–3 months, a 2nd-line treatment should be added.

Second Line

- If NSAIDs are ineffective in controlling the disease, or the patient has moderate to severe arthritis, a 2nd-line agent should be used, such as methotrexate or sulfasalazine.
- Methotrexate
 - If the arthritis does not respond to NSAIDs, methotrexate is the most common 2nd-line agent for active arthritis in multiple joints.
 - Laboratory values must be monitored closely in these patients, looking for bone marrow suppression or elevation of transaminase levels.

- Sulfasalazine
 - Most often used in ERA

Third Line

- Biologic agents are often added when patients do not respond adequately to methotrexate or cannot tolerate its side effects, or when the arthritis is severe.
- Antitumor necrosis factor therapy is frequently used:
 - Etanercept is a receptor for tumor necrosis factor; given SC once or twice a week
 - Infliximab is a chimeric antibody to tumor necrosis factor; given IV every 4–8 weeks
 - Adalimumab is a fully humanized antibody to tumor necrosis factor; given SC every other week
- IL-1 inhibition may work better than TNF inhibition in systemic JIA.
 - Anakinra is a recombinant IL-1 receptor antagonist. Given as a daily SC injection
 - Canakinumab is given SC once monthly.
 - Rilonacept is an SC injection given weekly.
- Anti-IL-6 therapy (tocilizumab)
 - An IV medication given every other week.
 - It has been approved for children with systemic-onset and polyarticular JIA.
- Abatacept
 - Costimulation blocker. It blocks the interaction of CD28 on T cells with CD80 and CD86 receptors on antigen-presenting cells.
 - It is given IV every 4 weeks.
 - It is currently being tested as an SC injection in children (SC form is approved in adults).
- Rituximab
 - An antibody to CD20, which is present on all B cells
 - Approved for use in adult RA but not JIA
- Medications such as cyclophosphamide or thalidomide are sometimes necessary to control severe systemic-onset JIA.

ADDITIONAL TREATMENT

General Measures

- Responses to treatments for juvenile idiopathic arthritis vary tremendously:
 - Some patients may respond to NSAIDs within 1–2 weeks.
 - Others take 4–6 weeks to improve, and some may not respond at all.
 - Steroids usually start to relieve symptoms within a few days.
 - Methotrexate usually takes 4–8 weeks until a benefit is seen.
 - Antitumor necrosis factor therapy can start decreasing symptoms in as little as 1–2 weeks, or it may take up to 3 months.
 - Other 2nd-line agents can take up to 16 weeks until the maximum benefit is seen.
- The waxing and waning nature of JIA itself adds to the variability of response to treatment.

ADDITIONAL THERAPIES

- Physical and occupational therapy are important in the management of JIA.
- The goal is to maintain range of motion, muscle strength, and function.

ONGOING CARE

PROGNOSIS

- Varies considerably
- Children with oligoarticular JIA usually do well and often go into remission within a few years of starting treatment. They may have flares, however, even up to 10 years after being symptom-free and off all medications.
- Patients with polyarticular JIA who are RF+ often develop a severe arthritis that may persist into adulthood.
- RF– polyarticular patients generally fare better, and many outgrow their disease.
- 50% of patients with systemic-onset JIA will develop severe chronic polyarticular arthritis.

COMPLICATIONS

- Joint degeneration with loss of articular cartilage

- Soft tissue contractures
- Leg length discrepancy
- Micrognathia
- Cervical spine dislocation
- Rheumatoid nodules
- Growth retardation
- Uveitis
 - Oligoarticular JIA, especially with a positive ANA test, is associated with chronic uveitis, which can lead to loss of vision if not detected early with routine slit-lamp eye examinations.
 - May be seen in polyarticular JIA but is less common
- Pericarditis, pleuritis, and severe anemia may develop in patients with systemic-onset JIA.
- Macrophage activation syndrome or hemophagocytic syndrome
 - Rare, but potentially lethal complication of systemic-onset JIA, resulting from an overproduction of inflammatory cytokines
 - May present as an acute febrile illness with pancytopenia and hepatosplenomegaly
 - Bone marrow aspiration can be diagnostic.
 - Treatment is often high-dose steroids and high-dose IL-1 inhibitors, or cyclosporine.

CODES

ICD10

- M08.80 Other juvenile arthritis, unspecified site
- M08.849 Other juvenile arthritis, unspecified hand
- M08.879 Other juvenile arthritis, unspecified ankle and foot

FAQ

- Q: Will the patient outgrow JIA?
- A: Prognosis depends on the type of JIA. In some studies, up to 50% of patients with JIA still had active disease 10 years after diagnosis, but only 15% had loss of function.
- Q: Will siblings of patients with JIA develop the disease?
- A: Rarely, but it can occur.

ASCARIS LUMBRICOIDES (ASCARIASIS)

Amaya L. Bustinduy

BASICS

DESCRIPTION

Ascaris lumbricoides is a large parasitic nematode (roundworm), 15–40 cm in length, which infects humans via eggs found in soil.

EPIDEMIOLOGY

- Geographic distribution: South America, sub-Saharan Africa, China, and East Asia
- All ages may be affected; however, children are more frequent hosts owing to oral behavior and tend to have a higher worm burden.
- Ascariasis is more common where sanitation is poor and population is dense.
- Eggs are viable in the soil for more than 6 years in temperate climates.
- It is the most prevalent helminth infection in the world.
- ~1/6 of the world's population is infected.
- 8–15% of infections are symptomatic.
 - 120–220 million cases
 - Mostly moderate and heavy worm loads

GENERAL PREVENTION

Infection control

- Sanitary disposal of human excrement, not using human feces as fertilizer, and hand washing has the potential to eliminate this infection.
- In communities with high transmission of *Ascaris*, community-wide mass drug delivery of anthelmintics is effective in controlling morbidity.

PATHOPHYSIOLOGY

- Fertilized eggs are ingested from soil contaminated with human feces.
- Larvae hatch in the small intestine and migrate to cecum and colon.

- Larvae invade the mucosa into the venous system and travel to the portal circulation, inferior vena cava, and finally, pulmonary capillaries.
- During migration through the pulmonary vessels, an eosinophilic response is evoked.
- Larvae penetrate the alveoli, are expelled by coughing, and swallowed back (days 10–14).
- Larvae become adult worms in the small intestine (day 24).
- Female worms excrete up to 200,000 eggs per day.
- Ingestion to excretion takes 2–3 months.
- Once in soil, fertilized eggs require 2–3 weeks of incubation in soil to become infectious and restart cycle.

ETIOLOGY

Children commonly acquire this infection from playing in dirt contaminated with *Ascaris* eggs.

COMMONLY ASSOCIATED CONDITIONS

- This infection may be associated with other soil-transmitted helminths:
 - Hookworm (*Necator americanus*, *Ancylostoma duodenale*)
 - *Trichuris trichiura*
 - *Strongyloides stercoralis*
 - *Toxocara canis*

DIAGNOSIS

HISTORY

- Gastrointestinal symptoms include the following:
 - Abdominal distention
 - Pain
 - Nausea
 - Diarrhea
 - Decreased appetite
- In the chronic phase, ascariasis is associated with the following:
 - Growth stunting
 - Cognitive delays

- Severe respiratory symptoms during the pulmonary migratory stage, when larvae cause an inflammatory response (Löeffler syndrome), characterized by the following:
 - Dyspnea
 - Cough
 - Fever
 - Shifting pulmonary infiltrates
 - Eosinophilia
- Severe presentation during the intestinal phase, when symptoms are due to the presence of worms:
 - Pain
 - Obstruction (2 per 1,000)
 - Peritonitis from perforation
 - Biliary colic, hepatitis, or pancreatitis from blockages due to worms
- History of passage of large worms in the stool or vomitus is suggestive of ascariasis.
- History of wheezing may precede passage of worms by 2–3 months.

PHYSICAL EXAM

- Chest: may have rales or wheezing if *Ascaris* larvae are in the lungs
- Abdomen
 - Distended
 - Auscultate and palpate for signs of obstruction or perforation.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Microscopic examination of stool specimens will demonstrate the characteristic ascaris eggs (round with thick shell).
- During the pulmonary phase, may have peripheral eosinophilia and larvae in sputum, but negative stool examinations
- Serologic tests are unnecessary and are poorly specific to the diagnosis.

Imaging

- Chest radiograph, if cough is present
- Abdominal imaging, if abdominal signs or symptoms of obstruction or perforation

DIFFERENTIAL DIAGNOSIS

Ascariasis should be considered in the differential diagnosis when a patient presents with pneumonia, peripheral eosinophilia, and/or intestinal obstruction in returned traveler or resident from an endemic area.

TREATMENT

MEDICATION

First Line

- Oral
 - Albendazole
 - 400 mg, single dose
 - WHO recommends 200 mg single dose for children <1 year old.
 - Mebendazole
 - 100 mg, b.i.d. for 3 days or 500 mg once
 - Ivermectin
 - 150–200 mcg/kg, single dose
- Alternatives (oral):
 - Pyrantel pamoate
 - 11 mg/kg to max 1 g per day for 3 days
 - Piperazine citrate
 - 75 mg/kg/24 h for 2 days; maximum, 3.5 g
 - Has been used historically for cases of intestinal obstruction (causes worm paralysis), but it is no longer available in the United States

SURGERY/OTHER PROCEDURES

Surgery or endoscopic retrograde cholangiopancreatography may be required for severe intestinal or biliary tract obstruction.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Treatment is highly effective.
- Reexamination of stool specimens 2 weeks after therapy can be

considered but is not essential.

- Reinfection is common in endemic areas and has led to mass drug administration programs.

Patient Monitoring

Warn parents about passage of worms in stool with treatment.

PROGNOSIS

- Once intestinal infection is detected and treated, the prognosis is excellent.
- If obstructive or respiratory complications have occurred, the prognosis is less favorable.
- The case fatality rate in cases with complications is up to 5%, most from obstruction.

COMPLICATIONS

- Bronchopneumonia may be seen during the pulmonary migrational stage, producing fever, cough, dyspnea, wheeze, eosinophilia, and pulmonary infiltrates (Löeffler syndrome).
- Heavy infestations may cause abdominal pain, malabsorption, and growth failure.
- Children may experience obstruction (ileocecal), malabsorption, or intussusception.
- Perforation or migration into the appendix, biliary, or pancreatic ducts may rarely occur.
- Hepatitis, acute cholecystitis, or pancreatitis can occur. Liver abscess can occur if intrahepatic ducts are obstructed.

CODES

ICD10

- B77.9 Ascariasis, unspecified
- B77.0 Ascariasis with intestinal complications
- B77.81 Ascariasis pneumonia

FAQ

- Q: What are the long term effects of untreated Ascaris infection in children?
- A: Growth stunting and cognitive delays are the most common long-term effects of untreated infections. Given the prevalence of this infection in the world, this is a major cause of morbidity in the world.

ASCITES

Rima Fawaz

BASICS

DESCRIPTION

- Ascites is defined as a pathologic accumulation of intraperitoneal fluid.
- Peritoneal fluid formation is a dynamic process of production and absorption.
- In children, ascites is usually the result of liver or renal disease.
- In adults, ascites is most often due to portal hypertension from cirrhosis.
- Ascites is the most common of the three major complications of cirrhosis; the other two complications of cirrhosis are hepatic encephalopathy and variceal hemorrhage.

PATHOPHYSIOLOGY

- Normal circulation
 - Blood enters the liver from the hepatic artery and portal vein, perfuses the hepatic sinusoids, and exits the liver via the hepatic veins.
 - Hepatic lymph, formed by the filtration of sinusoidal plasma into the space of Disse, drains from the liver via the transdiaphragmatic lymphatic vessels to the thoracic duct.
 - Hepatic lymph is isosmotic to plasma, as the sinusoidal endothelium is highly permeable to albumin.
 - In the intestine, the mesenteric capillary membrane is impermeable to albumin. The osmotic gradient favors the return of interstitial fluid/lymph into the capillary.
 - Intestinal lymph from regional lymphatics combines with hepatic lymph in the thoracic duct.
- Portal hypertension
 - Ascitic fluid production is due to a net transfer of fluid that exceeds the drainage capacity of the lymphatics.
- Cirrhotic ascites results from three pathophysiologic process:

- Portal hypertension
- Vasodilation: mediated predominantly by nitric oxide
- Hyperaldosteronism: Decreased effective volume sensed by the kidneys stimulate the renin-angiotensin-aldosterone system, leading to increased sympathetic activity and antidiuretic hormone secretion.
- Noncirrhotic ascites can be the result of the following:
 - Proteinaceous material produced by malignant cells or by inflammation of visceral and/or parietal peritoneum: peritoneal carcinomatosis, tuberculous ascites
 - Obstruction of lymphatic flow by mass, tumor, or external pressure
 - Impaired portal flow: right-sided heart failure, Budd-Chiari syndrome, portal venous malformations
 - Decreased effective arterial blood volume: heart failure
 - Decreased oncotic pressure/ hypoalbuminemia: nephrotic syndrome, protein-losing enteropathy, severe malnutrition
 - Primary (congenital) abnormalities of the lymphatics, metabolic disorders (lysosomal storage diseases including sialidosis, Wolman disease, GM1 gangliosidosis, Gaucher disease, and Niemann-Pick type C)
 - Rupture of intra-abdominal viscus or peritoneal/mesenteric cyst, bowel perforation, ureteral rupture

ETIOLOGY

Accumulation of fluid occurs with the following:

- Inflammatory conditions (e.g., mesenteric adenitis, tuberculosis, pancreatitis, secondary to inflammation of visceral, and/or parietal peritoneum)
- Portal hypertension or obstruction of portal vein flow and/or lymphatic flow by mass, tumor, or external pressure; tumors of abdominal viscera, retroperitoneum, thorax, or mediastinum (often characterized by chylous ascites)
- Infectious processes: abscess, tuberculosis, Chlamydia infection, schistosomiasis
- Gastrointestinal: infarcted bowel/perforation, pancreatitis, ruptured pancreatic duct, parenchymal liver disease

- Gynecologic: ovarian tumors, torsion, or rupture
- Renal: nephrotic syndrome, obstructive uropathy, perforated urinary tract, peritoneal dialysis
- Cardiac: CHF, constrictive pericarditis, inferior vena cava web
- Neoplastic: lymphoma, neuroblastoma
- Miscellaneous: systemic lupus erythematosus, eosinophilic ascites, chylous ascites, hypothyroidism, ventriculoperitoneal shunt

DIAGNOSIS

HISTORY

- The etiology for acute decompensation in hepatocellular function (e.g., massive bleeding, sepsis, superimposed infections) should be investigated.
- Weight gain
- Use of umbilical catheters in newborn period (increased risk of portal vein thrombosis)
- Evidence of chronic liver disease
- Respiratory distress
- Exposure to hepatotoxins
- Developmental delay or growth failure suggestive of metabolic disease

PHYSICAL EXAM

- Vital signs:
 - Increased heart rate (increased cardiac output)
 - Lower blood pressure seen in cirrhotics
- General appearance: cachexia
- Abdominal exam
 - Protuberant abdomen, bulging flanks (fluid wave or shifting dullness)
 - Caput medusae, umbilical hernia,
 - Dullness to percussion
 - Peritoneal signs
 - Abdominal pain
 - Splenomegaly

- Auscultation of the pericardium: pericardial friction rub (pericarditis), cor pulmonale
- Neurologic exam: hepatic encephalopathy
- Skin
 - Jaundice
 - Spider angioma
 - Palmar erythema
 - Scratch marks
 - Striae
 - Xanthomas
- Extremities
 - Clubbing
 - Edema

DIAGNOSTIC EVALUATION

Laboratory

- Complete blood count
- Electrolytes
- Liver test: transaminases, prothrombin time/international normalized ratio, total protein, albumin, total and fractionated bilirubin
- Amylase and lipase (to exclude pancreatitis)
- Creatinine and blood urea nitrogen
- Fluid cultures: blood, urine, ascitic fluid
- Urinalysis
- Specific testing for etiologies of ascites from chronic liver disease and other causes as deemed appropriate

Imaging

- Ultrasound of the abdomen with Doppler study
 - Study of choice to differentiate between free and loculated fluid collection and the presence of intra-abdominal masses
 - Can evaluate patency of hepatic and portal vasculature and directionality of flow
- Plain radiography (centralized bowel loops)
- Abdominal computed axial tomography
- Abdominal magnetic resonance imaging

Abdominal Paracentesis

- Ascitic fluid analysis is essential:
 - Cell count and differential
 - Albumin, total protein
 - Culture, Gram stain
 - Glucose (low in infection)
 - Lactate dehydrogenase concentration (high in infection, bowel perforation, or tumor)
 - Other optional tests include amylase (high in perforated viscus or pancreatitis), triglycerides (high in chylous ascites), and cytology (peritoneal carcinomatosis).
- Serum to ascites albumin gradient (SAAG)
 - (Serum albumin) – (ascites albumin)
 - Blood and ascitic fluid analysis should be obtained on same day.
 - $\text{SAAG} \geq 1.1 \text{ g/dL}$ suggests presence of portal hypertension.
 - If $\text{SAAG} < 1.1 \text{ g/dL}$, suspect other causes.

DIFFERENTIAL DIAGNOSIS

- Organomegaly: enlarged liver or spleen
- Mesenteric cyst or ovarian cyst: does not have shifting dullness when position is changed
- Bowel obstruction
- Cancer
- Heart failure
- Nephrotic syndrome

TREATMENT

- The management of the ascites should be directed toward the underlying etiology.
- Benefits of treatment of ascites should always be weighed against risks and complications of treatment.
- Mobilization of cirrhotic ascitic fluid is best accomplished by creating a negative sodium balance and then maintaining the balance.
- In patients with cirrhosis, causes of decompensation should be sought,

such as sodium and fluid overload, infection, esophageal hemorrhage, spontaneous bacterial peritonitis.

- In adults, dietary sodium intake is restricted to 44–88 mEq (1–2 g/24 h) or approximately 17–35 mEq (0.4–0.8 g) per thousand calories.
- In pediatrics, restricting dietary sodium intake is recommended: diet with no extra salt to a maximum 2 mEq/kg/24 h (to be balanced against palatability of food and nutritional needs).
- Water is only restricted in patients with profound hyponatremia (<125 mEq/L): 50–75% of maintenance requirements.
- Goal of diuretic therapy is reduction of bodyweight by 0.5–1% daily until ascites is resolved.
- Spironolactone (PO)
 - Most effective single diuretic, as it counteracts the hyperaldosteronism present in cirrhotic ascites
 - Acts on the distal collecting system, hence, inhibits reabsorption of 2% of filtered sodium
 - Bioactive metabolites have long half-lives, hence, need >5 days to achieve steady state.
 - Start at 2–3 mg/kg/24 h as a single morning (max 100 mg initial dose). In adults, typical starting dose is up to 100 mg/24 h and can be increased to max 400 mg/24 h.
 - Most effective in combination with furosemide
- Adequacy of spironolactone therapy can be monitored with urinary sodium excretion (desired >50 mEq/L). If no response, furosemide is added.
- Furosemide (PO)
 - Loop diuretic: can increase sodium excretion by 30%
 - Start at 1 mg/kg (max initial dose 40 mg), may increase every few days if needed.
 - Adults maintain ratio of 100 mg of spironolactone to 40 mg of furosemide to maintain eukalemia (max 400 mg spironolactone to 160 mg of furosemide daily)
- When diuretics are used, urine output and serum electrolytes should be closely monitored to prevent prerenal azotemia and decreased effective blood flow to the kidneys.

- Albumin: Supplementation may aid fluid mobilization if albumin is <2.5 g/dL (use 1 g/kg of 25% albumin until level >2.5 g/dL).
- Refractory ascites: Diuretic-refractory ascites derives from a lack of response to dietary sodium restriction and maximal diuretic therapy. Treatment options are the following:
 - Therapeutic abdominal paracentesis (large-volume paracentesis) is used in adults with refractory ascites.
 - In children, this approach is used to relieve respiratory distress or other sequelae of rapidly increasing intra-abdominal pressure.
 - Paracentesis of volumes >1 L should be accompanied by IV infusion of 25% albumin during the procedure.
 - Transjugular intrahepatic portosystemic shunting may be valuable in cases where portal hypertension is felt to be the underlying etiology of ascitic accumulation.
 - Orthotopic liver transplantation is the only curative therapy for refractory ascites from liver disease and the only definitive treatment that has been shown to improve survival.
- When diuretics are used, urine output and serum electrolytes should be closely monitored to prevent prerenal azotemia and decreased effective blood flow to the kidneys.

ALERT

- Ultrasonography should be the initial diagnostic imaging of choice for evaluation of ascites.
- With congenital ascites, evaluate for lysosomal storage diseases.
- Diagnostic paracentesis is crucial in the evaluation of new-onset ascites.
- Calculate SAAG to differentiate between portal hypertension and other causes.
- In patients with liver disease and new-onset ascites, evaluate for etiologies to explain acute decompensation.

PROGNOSIS

- Development of ascites in the setting of cirrhosis is a landmark in the natural history of cirrhosis: 15% of adult patients succumb in 1 year and 44% in 5 years.

- Liver transplantation dramatically improves survival.
- Prognosis depends on etiology of ascites: nephrotic syndrome (ascites will regress as proteinuria clears), infection, hepatic decompensation (prognosis improves if able to reverse cause of liver injury).

COMPLICATIONS

- Spontaneous bacterial peritonitis (SBP)
 - Spontaneous ascitic fluid infection: Infection of the peritoneal fluid may occur in the absence of secondary cause (e.g., bowel perforation or intra-abdominal abscess).
 - Fever, irritability, abdominal tenderness, and distention are common signs, vomiting and diarrhea may occur.
 - Abdominal paracentesis must be performed and ascitic fluid must be analyzed before a confident diagnosis of ascitic fluid infection can be made. The blood culture bottle should be injected with peritoneal fluid at the bedside in order to increase the culture yield.
 - Diagnosis: ascitic fluid absolute polymorphonuclear leukocytes ≥ 250 cells/mm³ without evidence of an intra-abdominal process
 - Bacterial organisms commonly identified are the following: *Streptococcus pneumoniae*, *Escherichia coli*, *Klebsiella pneumoniae*, enterococci, and *Haemophilus influenzae*.
 - Broad-spectrum antibiotics with gram-negative coverage such as third generation cephalosporin can be used until identification of bacterial pathogen allows narrower coverage.
 - Prophylaxis for recurrent SBP has been recommended in certain situations.
- Other complications:
 - Respiratory distress from decreased lung volume and diaphragmatic limitation: hepatic hydrothorax (large symptomatic pleural effusion that occurs in a cirrhotic patient in the absence of primary cardiopulmonary disease), abdominal wall hernias with rupture, tense ascites with leakage (especially after paracentesis)
 - Conservative management consists of appropriate initial therapy for most of these except hernia rupture, which requires surgical reduction.

CODES

ICD10

- R18.8 Other ascites
- R18.0 Malignant ascites
- A18.31 Tuberculous peritonitis

FAQ

- Q: What etiologies are likely in cases of congenital ascites?
- A: Lysosomal storage disorders and/or other metabolic diseases should be excluded. If hepatic function is impaired, causes of neonatal liver failure should also be investigated.
- Q: What is the best test to discriminate the type of ascites?
- A: Analysis of the peritoneal fluid collected by abdominal paracentesis is required for this purpose. The SAAG is helpful to discriminate ascites due to portal hypertension from other etiologies.
- Q: Where does the word “ascites” come from?
- A: It is thought that the word ascites is derived from the Greek word “askos” which refers to a container of wine or a wineskin.

ASPERGILLOSIS

Jessica E. Ericson • Daniel K. Benjamin, Jr.

BASICS

DESCRIPTION

- Diseases caused by species of the mold *Aspergillus* include superficial, immune-mediated, and invasive conditions depending on host factors.
- Most human disease is caused by *Aspergillus fumigatus*, *Aspergillus flavus*, or *Aspergillus niger*; other *Aspergillus* spp. may occasionally cause disease.

EPIDEMIOLOGY

- *Aspergillus* spp. are common, ubiquitous environmental saprophytic molds that are found growing in soil, grain, dung, bird droppings, and decaying plant matter.
- Reproduce through conidia (spore) formation. Spores are hardy and become airborne when soil is disturbed.
- Conidia are inhaled and are typically eliminated by alveolar macrophages and neutrophils.
- Disease occurs when airborne spores are inhaled but not effectively cleared; person-to-person spread does not occur.
- The incubation period has not been defined.
- Nosocomial infections can occur when ventilation or water systems become contaminated or when large numbers of spores become airborne during nearby construction or renovation projects.

Incidence

Aspergillosis incidence varies by the population studied. It is not common in a normal host. Ten percent of patients needing sinus surgery have *Aspergillus*. Up to 5% of leukemia and bone marrow transplant patients may develop invasive aspergillosis.

RISK FACTORS

- Otomycosis, fungal sinusitis, and allergic bronchopulmonary aspergillosis (ABPA) can occur in otherwise healthy patients.

- Most patients infected with *Aspergillus* have some degree of immunocompromise.
- Patients receiving chemotherapy for malignancy or rheumatologic disorders, chronic steroid therapy, organ and bone marrow transplant recipients, and those with HIV or primary immunodeficiencies are at increased risk.

GENERAL PREVENTION

- Hospitalized, immunosuppressed patients are at risk for invasive aspergillosis.
- Careful control of airflow using filters and laminar flow systems especially aimed at limiting exposure to air from construction sites is important.
- Shower heads should be cleaned regularly to prevent aerosolization of mold particles.

PATHOPHYSIOLOGY

- *Aspergillus* most frequently enters the body through the respiratory tract; however, the ear canal and breaks in the skin (especially if acquired from contact with a soiled surface) can also allow infection to occur.
 - Progression to disease depends largely on its ability to evade host defenses.
 - Macrophages and neutrophils can typically eliminate *Aspergillus* without difficulty, explaining its rarity in normal hosts.
 - *Aspergillus* produces proteolytic enzymes and cytotoxins, which may contribute to its pathogenesis.
- Conditions that alter the normal immunologic mechanisms predispose to invasive aspergillosis. Examples include leukemia (neutropenia), corticosteroids (decreased neutrophil mobilization and macrophage killing), and chronic granulomatous disease (decreased oxidative-mediated killing).

ETIOLOGY

Aspergillus sp.: *A. fumigatus* is most common and can cause the whole spectrum of disease. *A. niger* causes sinus and otomycosis and *A. flavus* causes sinus disease.

COMMONLY ASSOCIATED CONDITIONS

- Cutaneous: typically follows trauma, can also occur in premature infants or due to embolism in disseminated disease
- Otomycosis: typically a localized infection, often a superinfection of bacterial otitis externa. More common in warm, moist climates. Host may be normal or have altered mucosal immunity (diabetes, eczema, steroid use).
- Sinusitis: occurs as an aspergilloma, acute or chronic sinus disease. Normal and immunocompromised patients can be affected. Associated with nasal polyps and aspirin allergy in normal hosts.
- ABPA: an IgE-mediated hypersensitivity response to inhaled spores. Most commonly occurs in settings of chronic lung disease (cystic fibrosis, asthma). Often have wheezing, productive cough with brown sputum. Diagnostic criteria include +skin test to *Aspergillus* antigens, serum IgE >1,000 ng/mL, transient infiltrates on chest x-ray, total eosinophil count >500 cells/microliter.
- Aspergilloma: fungus balls that grow in preexisting lung cavities (congenital, secondary to TB, sarcoid, chronic lung disease)
- Invasive pulmonary aspergillosis occurs in the immunocompromised host, most commonly following bone marrow or solid organ transplants, and patients with hematologic malignancy or primary immunodeficiency. Invasion of blood vessels by *Aspergillus* leads to infarction, necrosis, and hematogenous dissemination; resulting pulmonary hemorrhage is often fatal.
- Invasive aspergillosis in immunocompromised hosts can disseminate to the sinuses, brain, or skin. Rarer infections include endocarditis, meningitis, osteomyelitis, esophagitis, or infection of the eye.

DIAGNOSIS

HISTORY

- Otomycosis: ear pain, pruritus, hearing loss
- Sinusitis: environmental allergies, chronic congestion, sinusitis unresponsive to antibiotics
- ABPA: unexplained worsening of asthma symptoms, cough productive

of dark mucous plugs

- Lung disease: exposure to construction site or gardening (especially involving mulch or compost)
- Immunity: Is the patient immunocompromised?
 - Immunocompromised patients, especially those with prolonged neutropenia, are at highest risk for invasive aspergillosis.

PHYSICAL EXAM

- Cutaneous: necrotic-appearing painful ulcer
- Otomycosis: relapsing otorrhea with thick greasy exudate and pain on tragal movement. Black spores (*A. niger*) may be visible in the canal. Rarely invasive but may cause facial nerve palsy if it is.
- Sinusitis: Nasal obstruction, polyps, facial pain, and proptosis are typically seen. Invasive sinus aspergillosis may also cause monocular blindness and bony destruction on radiographic films, with erosion into the orbit or the cranial vault, or with widespread dissemination. The maxillary sinuses are most commonly involved.
- Lung disease: often indistinguishable from other causes of pneumonia on physical examination. Fever, tachypnea, rales, hypoxemia, and hemoptysis (due to angioinvasion) may be present.

DIAGNOSTIC TESTS & INTERPRETATION

Lab & Radiography

- *Aspergillus* can be isolated from nearly any body site including blood, cerebrospinal fluid, sputum, urine, bronchoalveolar lavage (BAL) fluid, and tissue biopsy specimens.
- Respiratory specimens growing *Aspergillus* spp. on culture (e.g., sputum and nasal cultures) may represent colonization in the immunocompetent host but may indicate invasive disease in certain hosts. The entire clinical picture including history and physical exam should be considered when interpreting culture results.
- Presence of branching, septate hyphae on stained biopsy specimens or a wet preparation performed with 10% potassium hydroxide (KOH) is suggestive of *Aspergillus* or other mold species.
- Cutaneous aspergillosis, otomycosis, and sinusitis: Suggestive lab findings include biopsy culture growing *Aspergillus* sp., pathology

specimen with septate hyphae on KOH preparation in the setting of a consistent clinical picture.

- Sinusitis and ABPA: may also see elevated serum IgE, eosinophilia, Aspergillus-specific serum IgE, and an immediate-type skin test response to Aspergillus antigen which may support diagnosis
- Isolation of Aspergillus sp. by culture is ideal but often does not occur in pulmonary and disseminated disease.
- Radiographic studies may support the diagnosis but are not definitive.
 - ABPA: centrilobular nodules, “finger in glove,” upper lobe infiltrate
 - Pulmonary disease: cavitations, nodules (seen in ~35%). Classic CT findings of “halo sign” (an area of low attenuation surrounding a nodule) initially and later the “crescent sign” (an air crescent near the periphery of a lung nodule, caused by contraction of infarcted tissue) are seen infrequently in children but may be present in adolescents.
- Adjunctive tests: Galactomannan is a polysaccharide of Aspergillus cell walls. Enzyme immunoassay (EIA) for galactomannan from serum or BAL fluid early in the course may aid diagnosis of aspergillosis in immunocompromised children.

DIFFERENTIAL DIAGNOSIS

- Bacterial sinusitis, otitis, or pneumonia
- Asthma, cystic fibrosis
- Nocardia, Streptococcus pneumoniae, and Staphylococcus aureus can cause similar-appearing pulmonary lesions.

TREATMENT

MEDICATION

First Line

Voriconazole is primary therapy for invasive aspergillosis. Treatment is generally at least 12 weeks. Therapeutic drug monitoring should be performed because of interpatient variability.

Second Line

- Echinocandins (micafungin, caspofungin)

- Amphotericin B and the lipid-based amphotericin products can be used for salvage therapy or empirically in cases when mold is suspected and zygomycetes cannot be ruled out. Lipid-based products tend to have less toxicity and may be better tolerated.
- Posaconazole: requires that patients tolerate a fatty diet for optimal absorption
- Itraconazole is occasionally used as step-down therapy for mild to moderate aspergillosis, but with newer agents, this is rarely necessary.

ADDITIONAL TREATMENT

General Measures

- Otomycosis: As it is often a coinfection with bacterial external otitis, treatment of the bacterial infection and debridement of canal debris is usually curative. Otic antifungal preparations or acetic acid may be considered if the tympanic membrane is intact.
- Sinusitis: If noninvasive, surgical drainage or debridement is usually curative.
- ABPA: First-line therapy is oral steroids. Addition of itraconazole or voriconazole may help refractory cases.
- Aspergilloma: Surgical excision is necessary as antifungals cannot penetrate cavitation well.

SURGERY/OTHER PROCEDURES

Surgical excision or localized debridement, in addition to antifungal medication, may be required for invasive disease. Mortality may be improved with surgical excision of lung lesions, but the procedure itself is often risky.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

Ongoing infections should be carefully monitored with serial radiographic studies as complications can be severe.

ALERT

- The classic radiographic findings of pulmonary aspergillosis are infrequently seen in children and their absence should NOT be used to eliminate *Aspergillus* as the causative agent.
- Evaluation for *Aspergillus* should be performed in immunocompromised patients with persistent fever who do not improve on broad-spectrum antibiotics; empiric antifungals should be considered.
- Aspergillosis in a normal host often does not require antifungal therapy.

PROGNOSIS

- Noninvasive disease (otomycosis, sinusitis) in the normal host usually resolves but may take several weeks.
- ABPA has variable outcomes: Resolution, steroid dependence, and ongoing lung destruction due to inflammatory dysregulation are all possible.
- Immunosuppressed or neutropenic patients may have rapid extension or dissemination of disease; prognosis is often very poor. Early recognition and aggressive treatment and debridement are necessary.

COMPLICATIONS

- Progression to invasive disseminated disease can occur as the initial manifestation if host factors are altered. Involvement of CNS, heart, or bones worsen prognosis.
- Otitis and sinusitis can erode through cranial bones to involve the orbits or CNS.
- Pulmonary disease can progress to pulmonary hemorrhage as angioinvasion occurs; respiratory failure or pneumothorax may develop as lung tissue is destroyed.

CODES

ICD10

- B44.9 Aspergillosis, unspecified
- B44.1 Other pulmonary aspergillosis
- B44.81 Allergic bronchopulmonary aspergillosis

FAQ

- Q: Is aspergillosis contagious?
- A: No. Disease is acquired by inhalation of airborne spores. People living or working in the same environment may be exposed to similar amounts of spores so clusters of infection are possible.

ASPLENIA/HYPOSPLENIA

Joseph A. Picoraro • Sarah S. Lusman

BASICS

DESCRIPTION

- Asplenia is the absence of the spleen due to either a congenital anomaly or a surgical procedure.
- Hyposplenia is the reduced or absent function of the spleen, impairing the capacity to prevent bacterial infections.

EPIDEMIOLOGY

- The exact incidence is not known.
- Asplenia is present in about 3% of neonates with structural heart disease.
- Isolated asplenia is most often recognized at autopsy.

PATHOPHYSIOLOGY

- The spleen is a major component of the reticuloendothelial system; it is important both for antibody synthesis and for clearance of opsonized organisms by phagocytosis.
- Antibody-mediated phagocytosis is the primary mechanism to destroy encapsulated microbes, such as pneumococcus, meningococcus, and Haemophilus.
- In the absence of the spleen's phagocytic pathway, the polysaccharide-rich capsules of these bacteria protect them from destruction and permit them to effect systemic bacterial infection that may lead to overwhelming sepsis.
- For patients <4 years of age in whom few alternate routes of bacterial clearance exist, significant pathology can result from impaired splenic function.

ETIOLOGY

- Surgical splenectomy
- Congenital asplenia

- In association with certain diseases or conditions (see “[Differential Diagnosis](#)”)

COMMONLY ASSOCIATED CONDITIONS

- Besides splenectomy, when asplenia is known, patients with certain diseases are at risk of asplenia or hyposplenia (see “[Differential Diagnosis](#)”).
- Asplenia or hyposplenia should be suspected in any patient with overwhelming infection with an encapsulated organism.

DIAGNOSIS

HISTORY

- Any patient with a condition known to be associated with asplenia/hyposplenia (see “[Differential Diagnosis](#)”) deserves evaluation for splenic function.
- In the apparently healthy child with no identified risk factors who presents with an overwhelming infection with an encapsulated organism, a blood smear should be examined for signs of hyposplenism (see “[Lab](#)”).

PHYSICAL EXAM

- The spleen may be normal, large, or nonpalpable. Therefore, the size of the spleen cannot be used as an indicator of splenic function.
- The size is most closely linked to the underlying etiology.
 - Portal hypertension or complete splenic replacement by cysts, neoplasm, or amyloid can lead to splenomegaly.
 - Sequestration crises such as those associated with sickle cell disease and malaria clog the spleen with cellular debris, which may also result in increased spleen size.
 - Sickle cell disease patients typically have splenomegaly early in life, as the spleen tends to sequester the abnormal red cells. With time, the spleen slowly autoinfarcts and eventually becomes nonpalpable.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- The reduction or absence of splenic function can be determined by specific hematologic changes detectable on a blood smear.
 - The spleen normally removes intercellular debris such as Howell-Jolly bodies (nuclear remnants), Heinz bodies (denatured hemoglobin), and Pappenheimer bodies (iron granules).
 - Findings of target cells (red cells with a bull's eye center due to excessive membrane relative to the amount of iron and hemoglobin), Howell-Jolly bodies, Heinz bodies, Pappenheimer bodies, and pitted (or pocked) erythrocytes are indicative of hyposplenism or asplenia.
- Surface indentations, pits or “pocks,” of the red cell surface when seen in >12% of red blood cells are the most sensitive indicator of hyposplenism. These are submembranous vacuoles that can be seen only in wet preparations of red cells fixed in 1% glutaraldehyde and viewed using direct interference-contrast microscopy.

Imaging

- US with Doppler: to assess spleen size and direction of flow in splenic vein and portal vessels
- CT/MRI: to detect polysplenia
- Radionuclide (technetium-99m) liver/spleen scan: to detect functional reticuloendothelial cells

DIFFERENTIAL DIAGNOSIS

Diminished splenic function is associated with the following:

- Congenital
 - Isolated congenital asplenia
 - Heterotaxy syndrome
- Hematologic
 - Sequestration crises (e.g., sickle hemoglobinopathies, essential thrombocytosis, malaria)
 - Sickle cell disease
 - Hereditary hemoglobinopathies
- Autoimmune
 - Glomerulonephritis

- Systemic lupus erythematosus
- Rheumatoid arthritis
- Sarcoidosis
- Sjögren syndrome
- Graves disease
- Graft-versus-host disease
- GI/hepatic
 - Celiac disease
 - Inflammatory bowel disease
 - Chronic liver disease/portal hypertension
- Space-occupying lesions
 - Tumors, such as lymphoma
 - Amyloidosis
 - Cysts
- Postsplenectomy
 - Trauma
 - β -Thalassemia
 - Hereditary spherocytosis
- Vascular
 - Splenic artery occlusion
 - Splenic vein thrombosis
- Miscellaneous:
 - Normal infants
 - Elderly
 - Bone marrow transplant
 - HIV infection
- Splenic irradiation

TREATMENT

GENERAL MEASURES

- Immunization with pneumococcal, meningococcal and Haemophilus vaccines should be carried out in all patients with asplenia/hyposplenia.
- In those patients who will be undergoing a scheduled splenectomy, the

pneumococcal, meningococcal, and Haemophilus vaccines should be given at least 14 days prior to the operation.

- All children between 6 weeks and 59 months of age should receive the 4-dose series of the 13-valent pneumococcal conjugate vaccine (PCV13).
 - In children 2–5 years of age with asplenia/hyposplenia, the 23-valent pneumococcal polysaccharide vaccine (PPSV23) should be administered following the 4-dose series of PCV13.
 - A repeat of the PPSV23 should be administered 5 years after the initial dose.
- Infants between 6 weeks and 18 months of age with asplenia/hyposplenia should receive the 4-dose series of the meningococcal groups C and Y and Haemophilus influenzae b tetanus toxoid conjugate vaccine (Hib-MenCY-TT).
 - Children older than 19 months should wait until 2 years of age and then receive the 2-dose series of the quadrivalent meningococcal conjugate vaccine (MenACWY).
 - Revaccination is recommended every 5 years.
- Children should also receive the Haemophilus influenzae type b vaccine if not completed, as above.
- Antimicrobial prophylaxis should be strongly considered in all children with asplenia/hyposplenia.
 - Penicillin or amoxicillin is most commonly used; however, with increasing penicillin resistance, it may be replaced by amoxicillin-clavulanic acid, fluoroquinolones, or cefuroxime.
- Sick cell patients have impaired splenic function at all stages and should receive antimicrobial prophylaxis.

INPATIENT CONSIDERATIONS

Any patient with asplenia/hyposplenia with a febrile illness should be evaluated for systemic bacterial illness. Blood culture with broad-spectrum antibiotic coverage should be strongly considered.

ONGOING CARE

PATIENT EDUCATION

- Patients should be counseled regarding the risk of bacterial infection and considerations in setting of febrile illness.
- MedicAlert bracelets/necklaces can be used to indicate splenic function and risk of sepsis.

COMPLICATIONS

- Bacteremia
 - For asplenic or hyposplenic patients, risk of bacteremia is highest in younger children and in the years immediately following splenectomy.
 - The most common pathogens causing bacteremia are the encapsulated organisms, *Streptococcus pneumoniae*, *Haemophilus influenzae*, and *Neisseria meningitidis*.
 - There is also an increased risk of infection with *Babesia microti* and *Plasmodium falciparum* (intraerythrocytic parasites) and *Capnocytophaga canimorsus* (via dog bites).

ALERT

Generally, for patients <4 years, splenectomy is contraindicated because of the risk of developing bacterial infection.

CODES

ICD10

- Q89.01 Asplenia (congenital)
- Z90.81 Acquired absence of spleen
- D73.89 Other diseases of spleen

FAQ

- Q: What should I do if my child has a fever?
- A: All patients with asplenia/hyposplenia should be evaluated for a serious bacterial infection and treated appropriately.
- Q: Are there any special times I need to worry about infections?
- A: Patients with asplenia/hyposplenia receiving dental work or GI endoscopy should be considered on a case-by-case basis. Antibiotic prophylaxis should be strongly considered in patients undergoing high-risk endoscopic procedures (i.e., sclerotherapy or stricture dilation). Rubin LG and, W Schaffner W. Clinical practice. Care of the asplenic patient. N Engl J Med. 2014;371(4):349–356.

ASTHMA

Lee J. Brooks

BASICS

DESCRIPTION

- Characterized by 3 components:
 - Reversible airway obstruction
 - Airway inflammation
 - Airway hyperresponsiveness to a variety of stimuli
- Diagnosis (the 3 “R”s)
 - Recurrence: Symptoms are recurrent.
 - Reactivity: Symptoms are brought on by a specific occurrence or exposure (trigger).
 - Responsive: Symptoms diminish in response to bronchodilator or anti-inflammatory agent.

ALERT

Pitfalls

- Not recognizing that asthma can manifest as chronic cough; wheezing may not be evident.
- Reluctance to “label” child with having asthma (using terms such as reactive airway disease or bronchitis)
- Frequent antibiotic or cough medicine use to treat asthma symptoms
- “Recurrent pneumonias” often are actually asthma exacerbations; subsegmental atelectasis on chest radiograph misdiagnosed as an infiltrate
- Underreporting of asthma symptoms; beware of the child who “doesn’t like to play sports”; he/she may have learned that exercise causes dyspnea.
- Poor adherence with therapy when symptoms are controlled
- Failure to use inhaled medications properly: Inhaled medication use must be taught and reviewed at each visit. A fixed-volume holding chamber should always be used with a pressurized metered-dose inhaler (pMDI), regardless of patient age. pMDIs should be refilled

based on the number of doses used, not by estimating contents by shaking or spraying. pMDIs with a built-in dose counter are preferred.

EPIDEMIOLOGY

Incidence

- Most common chronic illness in children
- About 20% of children are diagnosed with asthma at some point before age 20 years.
- Death from asthma in children more than tripled from 1979 to 1996 but has been decreasing since then, perhaps owing to better recognition and increased use of anti-inflammatory medications. The incidence of death from asthma does not seem to correlate with severity.

Prevalence

- Wheezing in children is extremely common in the industrialized world (cumulative prevalence, 30–60%).
- In younger children, most episodes occur following viral infections.
- >50% of children who wheeze in early childhood stop wheezing by age 6 years.
- 14% of all young children (40% of those who wheeze during infancy) continue to wheeze.

RISK FACTORS

Genetics

- Children of asthmatics have higher incidence of asthma.
 - 6–7% risk if neither parent has asthma
 - 20% risk if 1 parent has asthma
 - 60% risk if both parents have asthma
- Several genes are known to be associated with the development of atopy and bronchial muscle responsiveness.

GENERAL PREVENTION

- Patient and caregiver education is mandatory to establish provider/caregiver partnership and ensure adherence with treatment plan.
- Every patient/caregiver should be taught that asthma is a chronic, inflammatory condition that can be controlled with proper therapy.

- All medications should be explained and potential risks (side effects) and benefits reviewed.
- A written asthma management plan should be provided, outlining daily therapy and an “action plan” for managing exacerbations of asthma.
- Environmental counseling:
 - Avoid airborne irritants (tobacco smoke, wood stoves, noxious fumes).
 - Minimize dust-mite exposure.
 - Minimize stuffed animals, quilts, books, and clutter.
 - Use dust mite–proof coverings on mattresses, pillows, and box springs.
 - Wash pillows, blankets, and sheets in hot water.
 - Avoid molds by decreasing relative humidity to 50%.
 - Remove pets from child’s bedroom and from house if patient is allergic to the animal.

PATHOPHYSIOLOGY

- Immune and inflammatory responses in the airways are triggered by an array of environmental antigens, irritants, or infectious organisms.
- Atopy and asthma are related.
 - Eosinophilia and the ability to make excess IgE in response to antigen are associated with increased airway reactivity.
 - Asthma is more common in children who have allergic rhinitis and eczema.
- Viral infections, particularly respiratory syncytial virus (RSV) during infancy, may play a role in the development of asthma or may modify the severity of asthma.
- Exposure to cigarette smoke and other airway irritants influences the development and severity of asthma.
- Airway is stimulated and primary inflammatory mediators released.
- Airway is invaded by inflammatory cells (mast cells, basophils, eosinophils, macrophages, neutrophils, B and T lymphocytes).
- Inflammatory cells respond to and produce various mediators (cytokines, leukotrienes, lymphokines), augmenting the inflammatory response.
- Airway epithelium is inflamed and becomes disrupted, and basal

membrane is thickened.

- Airway smooth muscle is hyperresponsive, and bronchoconstriction ensues.
- Airway smooth muscle hypertrophy and airway epithelial hyperplasia are characteristic chronic changes resulting from poorly controlled asthma.

DIAGNOSIS

HISTORY

- Inquire about these symptoms: coughing, wheezing, shortness of breath, chest tightness:
 - Frequency of symptoms defines severity.
 - Precipitating factor (trigger)
 - Response to bronchodilator or anti-inflammatory medication
 - Family history of asthma or atopy
- Pattern of symptoms:
 - Perennial versus seasonal
 - Continuous versus acute
 - Duration and frequency of episodes
 - Diurnal variation/nocturnal symptoms
- Do any of the following set off the breathing difficulty?
 - Infections (upper respiratory, sinusitis)
 - Exposure to dust (mites), animal dander, pollen, mold
 - Cold air or weather changes
 - Exercise or play
 - Environmental stimulants (e.g., cigarette smoke, strong odors, pollutants)
 - Emotional factors (e.g., laughing, crying, fear)
 - Drug intake (aspirin, nonsteroidal anti-inflammatory drugs, β -blockers)
 - Food additives
 - Endocrine factors (e.g., menses, pregnancy, thyroid dysfunction)
- Review of systems:
 - Symptoms of complicating factors (gastroesophageal reflux,

sinusitis, allergies)

- Dyspepsia, sour taste (gastroesophageal reflux); throat clearing, purulent nasal discharge, halitosis, cephalalgia, or facial pain (sinusitis); nasal itching (“allergic salute”), eye rubbing, sneezing, watery nasal discharge (allergies)
- Impact of asthma:
 - Number of hospitalizations/intensive care unit admissions
 - Number of emergency room visits/doctor’s office visits
 - Asthma attack frequency
 - Number of missed school days/parent workdays
 - Limitation on activity (may be subtle)
 - Number of courses of systemic steroids needed
- Environmental history:
 - Type of home
 - Location of home (urban, suburban, rural)
 - Heating system/air conditioning
 - Use of humidifier
 - Presence of molds, cockroaches, rodents
 - Fireplace/wood burning stove
 - Carpeting
 - Stuffed animals
 - Pets
 - Exposure to cigarette smoke

PHYSICAL EXAM

- Pulmonary exam may be normal when asymptomatic.
- Assess work of breathing:
 - Level of distress
 - Intercostal/supraclavicular muscle retractions
- Chest shape (i.e., normal vs. barrel-shaped)
- Lung auscultation:
 - Wheezing
 - End-expiratory involuntary cough
 - Prolonged expiratory phase
 - Crackles or coarse breath sounds
 - Stridor (indicates extrathoracic airway obstruction)

- Head, eyes, ears, nose, and throat exam: signs of allergies or sinusitis:
 - Watery or itchy eyes
 - Allergic shiners
 - Dennie lines
 - Nasal congestion
 - Boggy nasal turbinates
 - Nasal polyps
 - Postnasal drip
- General exam (vital signs):
 - Blood pressure (pulsus paradoxus)
 - Respiratory rate (tachypnea)
- Skin: evidence of eczema
- Extremities: digital clubbing (very rare in asthma; suggests alternative diagnosis)
- Physical exam pearl: forced-exhalation maneuver to observe for wheezes or for precipitating coughing

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Pulmonary function tests
 - Very sensitive; may show airway obstruction even when the physical exam is normal
 - Essential for the assessment and ongoing care of children with asthma
 - Spirometer measures the degree of airway obstruction and the response to bronchodilators.
 - Values obtained can measure absolute degree of airway obstruction.
 - Serial values can follow progress of disease and response to treatment.
 - Children as young as 4–5 years old can usually perform spirometry with practice.
- Provocational testing
 - Exercise challenge: determines effect of exercise on triggering airway obstruction
 - Cold-air challenge: indirect test of airway hyperresponsiveness
 - Methacholine challenge: A positive test supports the diagnosis of

asthma (useful in cases for which history is equivocal and pulmonary function test is normal), measures the degree of airway hyperreactivity.

- Allergy evaluation:
 - Blood tests (eosinophil count, IgE level)
 - Skin testing (best test for assessing allergen sensitivity)
 - RAST testing (not as accurate as skin testing)
 - Sputum/nasal examination for presence of eosinophilia
- Exhaled nitric oxide
- Identifies Th2-mediated airway inflammation
- May identify/exclude steroid responsive airway inflammation
- Other studies:
 - Gastroesophageal reflux evaluation
 - pH probe
 - Milk scan
 - Barium swallow (confirms normal anatomy)
- Peak flow meter (home testing)
 - Measures peak flow rate (PEFR)
 - Effort-dependent
 - Assesses central, not peripheral, airway obstruction
 - Used with patients who have poor symptom recognition or labile asthma
 - Dips in peak flow rate precede onset of clinical asthmatic symptoms.
 - Peak flow rate should be performed at least once a day.
 - Peak flow rate values are divided into 3 zones:
 - ▢ Green: $\geq 80\%$ of baseline
 - ▢ Yellow: 50–80% of baseline
 - ▢ Red: 50% of baseline
- Specific peak flow rate guidelines should be individualized for each patient based on the best measurement obtained during a 14-day period when the child is well.

Imaging

- Chest radiograph
 - Can be obtained if the diagnosis is uncertain or there is not the

expected response to treatment, to rule out congenital lung malformations or obvious vascular malformations

- ▣ Findings can be normal.
- ▣ Common findings are peribronchial thickening, subsegmental atelectasis, and hyperinflation.
- Sinus CT is useful if symptoms suggest sinusitis.
- Chest CT should be performed if bronchiectasis or anatomic abnormality is suspected.

Diagnostic Procedures/Other

Bronchoscopy can rule out anatomic malformations, foreign bodies, mucous plugging, vocal cord dysfunction, and aspiration (lipid-laden macrophages).

DIFFERENTIAL DIAGNOSIS

- Infectious
 - Pneumonia
 - Bronchiolitis
 - Chlamydia infection
 - Laryngotracheobronchitis
 - Sinusitis
 - Immune deficiency
- Mechanical
 - Extrinsic airway compression
 - Vascular ring
 - Foreign body
 - Vocal cord dysfunction
 - Tracheobronchomalacia
- Miscellaneous:
 - Cystic fibrosis
 - Bronchopulmonary dysplasia
 - Pulmonary edema
 - Gastroesophageal reflux
 - Recurrent aspiration
 - Bronchiolitis obliterans

TREATMENT

MEDICATION

- Corticosteroids (anti-inflammatory agents)
 - Most effective anti-inflammatory agents
 - Inhaled: reduce airway inflammation and hyperresponsiveness more than any other inhaled agents; inhibit production and release of cytokines and arachidonic acid–associated metabolites; enhance β -adrenoreceptor responsiveness
 - Side effects include oral thrush; may minimally affect growth velocity at moderate or high doses
 - Dosage individualized to each patient (see [Figure 5](#) in Appendix for Stepwise Approach for Managing Asthma Long Term). Agents vary in topical potency and systemic bioavailability; available as pMDIs, dry-powder inhalers (DPIs), or nebulized. Fluticasone (Flovent) 44, 110, 220 mcg/puff pMDI and 50, 100, 250 mcg DPI; budesonide (Pulmicort) 90, 180 mcg/puff DPI and 250, 500, and 1,000-mcg vials for nebulizer; beclomethasone (Qvar) 40, 80 mcg/puff; flunisolide (AeroBid) 80 mcg/puff; ciclesonide (Alvesco) 80, 160 mcg/puff; mometasone (Asmanex) 100 mcg/puff pMDI and 110, 220 mcg DPI (see [Table 14](#) in Appendix for Comparative doses)
 - Oral: used for asthma exacerbations or for severe asthma that cannot be otherwise controlled.
 - Exacerbations: prednisone or prednisolone 1–2 mg/kg/24 hr for 3–7 days or longer; usually tapered if >7 days of therapy required or if systemic steroids are used frequently. Shorter 2-day courses of oral dexamethasone have also been described in clinical trials.
 - Ongoing therapy: 0.5–1 mg/kg/24 hr daily or every other day for patients with severe asthma
 - Undesirable side-effect profile. When used daily, assess bone density and for cataract formation at least yearly.
 - IV: Methylprednisolone (Solu-Medrol) 1–2 mg/kg/24 hr IV divided q6–12h until improved and able to take oral medication
- Leukotriene modifiers (anti-inflammatory agents)

- Block the synthesis and/or action of leukotrienes
- 5-lipoxygenase inhibitors, zileuton: may cause hepatic dysfunction
- Leukotriene receptor antagonists: zafirlukast (10 mg; Accolate) and montelukast (4, 5, and 10 mg; Singulair)
- Indicated as monotherapy for mild or exercise-induced asthma and in combination with an inhaled corticosteroid for more effective symptom control or using a lower dose of inhaled corticosteroid
- Mast-cell stabilizers
 - Weak anti-inflammatory agents
 - Preparations: cromolyn sodium; nedocromil sodium (Tilade, available in Canada)
 - Decrease bronchial hyperresponsiveness
 - Can be used prior to exercise for exercise-induced symptoms
 - No significant side effects
 - Inhaled: nebulizer; MDI
- β_2 -Agonists (bronchodilators)
 - Indication is for relief of acute bronchoconstriction (quick-relief medicine); used as needed in people with asthma who have breakthrough symptoms; used prior to exercise in exercise-induced bronchospasm
 - Regular use or overuse associated with worsened control of asthma
 - Routes include metered-dose inhaler or nebulizer
 - Short-acting (4–6 hours) preparations include albuterol (Ventolin, Proventil, ProAir), terbutaline (Brethaire, Brethine), and metaproterenol (Alupent); a single-isomer preparation of albuterol (Xopenex) may have a slightly longer duration of action and perhaps fewer side effects.
 - Longer acting (up to 12 hours) preparations include salmeterol (Serevent) and formoterol (Foradil) available as pMDI, and DPI can be used daily in conjunction with anti-inflammatory agent for improved symptom control.
 - Fixed combination products of inhaled corticosteroid and a long-acting β -agonist (Advair, Dulera, Symbicort) are available as DPIs and pMDIs.
- There may be an increased risk of asthma-related deaths in patients

using long-acting β -agonists (LABAs), and it is suggested that LABAs be prescribed only for patients not adequately controlled on other asthma-controller medications or whose disease severity warrants initiation of treatment with 2 maintenance therapies.

- Theophylline (bronchodilator)
 - 2nd-line agent used when more conventional therapies are unsuccessful
 - Indications are chronic, poorly controlled asthma and nocturnal asthma (if no gastroesophageal reflux); adjunctive therapy with β_2 -drugs and steroids in hospitalized patients in selected cases; route (oral or IV); serum levels must be routinely monitored (therapeutic levels are 10–20 mg/mL).
 - Side effects are seen with increased levels.
 - Many factors affect theophylline levels. Increased levels are seen with erythromycin, ciprofloxacin, cimetidine, viral illnesses, fever. Decreased levels are seen with phenobarbital, phenytoin, rifampin.
 - Sustained-release tablets should not be crushed.
- Anticholinergic agents (bronchodilators): Adjunctive bronchodilators may be useful in patients who only partially respond to β -agonists; preparations include ipratropium bromide MDI or ampule for nebulization (Atrovent).
- Monoclonal antibodies against IgE (Xolair) can be given as a monthly SC injection in severe asthma patients with moderately high IgE levels.

ISSUES FOR REFERRAL

- A patient who requires hospitalization more than once a year, or who has required intensive care
- A patient who requires frequent bursts of systemic corticosteroids
- A patient whose airway obstruction is not easily reversible
- A patient who has clinical features suggesting another pulmonary process

COMPLEMENTARY & ALTERNATIVE THERAPIES

- Miscellaneous drugs used in severe cases
- Steroid-sparing agents:
 - Troleandomycin (TAO): Macrolide antibiotic decreases clearance of

corticosteroids, thus prolonging the effects of corticosteroids on the lung; lower corticosteroid dosing required

- Methotrexate: Potent immunosuppressive drug needs further investigation in children.
- Cyclosporine: shown to have steroid-sparing effect in adult population with asthma; side effects are significant and may limit use.
- Magnesium sulfate (MgSO_4): used intravenously as a smooth muscle relaxer in severe acute asthma exacerbation
- Helium
 - May improve airflow in severe asthma
 - Can improve ventilation and potentially oxygenation
- Immunotherapy
 - Efficacy in asthma is controversial.
 - Most effective if a single antigen can be identified
 - Used only in select cases if medical management and environmental control measures are ineffective

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Long-term follow-up is essential to maintain normal activity and pulmonary function. All patients should use a valved holding chamber with pMDIs, and technique for all inhaled medications should be reviewed regularly.

Patient Monitoring

Signs that may indicate problems: increased symptoms (cough day or night, wheeze), exercise limitations or symptoms during exercise, decrease in peak flow rate, increasing use of inhaled bronchodilators, subject not improving on enhanced home therapy. For patients requiring a daily controller medication, regularly assess level of asthma control based on a standard clinical instrument (e.g., pediatric asthma control test [P-ACT], the Asthma Therapy Assessment Questionnaire for children and adolescents [the pediatric ATAQ]). If asthma not well controlled, consider

increasing level of daily controller medication.

DIET

- Avoid foods or food additives (if truly allergic).
- Food-induced asthma is uncommon.

PATIENT EDUCATION

Activity

- Most patients with asthma can participate fully in sports, even at a high level, with close follow-up. Extra medications such as albuterol and/or cromolyn may be required before vigorous exercise. All athletes should have their quick-relief medications on hand at all times.
- Athletes with asthma may need to report their medications to the governing bodies of their sport.

PROGNOSIS

With proper therapy and good adherence to treatment regimen: excellent

COMPLICATIONS

Morbidity: frequent hospitalizations and absence from school.

Psychological impact of having a chronic illness. Decline in lung function over time

CODES

ICD10

- J45.909 Unspecified asthma, uncomplicated
- J45.901 Unspecified asthma with (acute) exacerbation
- J45.990 Exercise induced bronchospasm

FAQ

- Q: Will my child outgrow his or her asthma?
- A: Family history and allergies affect the ultimate outcome. Wheezing during the 1st 3 years of life is extremely common, with 40–50% of all

children wheezing at some time. Many of these children do not develop asthma and “outgrow” their illness by school age. Some patients develop asthma again as young adults.

- Q: Can my child become dependent on asthma medications?
- A: Children do not become “dependent” on these medications as they would with narcotic agents. Daily asthma medications are required to maintain airway patency and to control airway inflammation.
- Q: Will my child be on medications for the rest of his or her life?
- A: This depends on the severity of the asthma. The types, doses, and frequency of asthma medications will change over a patient’s lifetime.

ATAXIA

Kristin W. Barañano

BASICS

DESCRIPTION

- Ataxia refers to incoordination of movement out of proportion to weakness.
- Can be caused by dysfunction of cerebellum, proprioception, or vestibular system
- Careful history of timing of onset and antecedent events key in framing differential: acute, subacute, chronic/progressive, episodic

EPIDEMIOLOGY

- Acute cerebellar ataxia (ACA) was previously seen in 1 per 5,000 cases of varicella, accounting for 25% of total cases. The risk following varicella-zoster virus (VZV) vaccination is 1.5 per 1,000,000 doses.
- Most cases of ACA are still postviral, followed by ingestions, then Guillain-Barré syndrome (GBS) (combined account for 80% of total).
- Dominantly inherited spinocerebellar ataxias (SCAs) are 1–5 per 100,000 but tend to have a later age of onset.
- More likely to see autosomal recessive (AR) ataxias in childhood; most common is Friedreich (FRDA) at 1 in 30,000–50,000

PATHOPHYSIOLOGY

- The cerebellum does not generate motor commands; instead, it modifies them to make them accurate and adaptive.
- The cerebellum receives input from the vestibular apparatus, spinal cord, and the cerebral cortex (via the pons).
- Both input and output is ipsilateral (i.e., right-sided cerebellar lesions cause right-sided ataxia).
- Midline cerebellum (vermis) controls gait, head and trunk stability, eye movements; lesions of vermis result in wide-based (“drunken sailor”) gait, truncal sway, and head titubation (bobbling movements).

- Cerebellar hemispheres control limb tone and coordination, motor learning, speech, eye movements; lesions of the cerebellar hemispheres cause limb dysmetria (trouble with finger nose finger testing).
- Function can be impaired by chemicals, autoimmune processes, genetic mutations; typical pathologic finding is loss of Purkinje cells and injury to their elaborate dendritic arbor.

ETIOLOGY

- Acute onset
 - Ingestions/intoxications: alcohol, anticonvulsants including phenytoin, benzodiazepines, antihistamines, heavy metals, carbon monoxide
 - Infections (e.g., Bartonella, Mycoplasma, Epstein-Barr virus)
 - Postinfectious
 - Postvaccination
 - Demyelinating events: multiple sclerosis, acute disseminated encephalomyelitis (ADEM) (can be associated with altered mental status and seizure), Miller Fisher variant of GBS (triad of ataxia, ophthalmoplegia, areflexia; look for eye movement abnormalities and areflexia)
 - Initial presentation of recurrent ataxia
- Subacute onset
 - Cerebellar hemorrhage
 - Ischemic stroke
 - Encephalitis or cerebellitis
 - Acute labyrinthitis/vestibular neuronitis (often prominent nausea/vomiting, hearing affected)
 - Posterior fossa tumors (e.g., medulloblastoma)
 - Paraneoplastic syndromes (opsoclonus-myoclonus syndrome, with multidirectional chaotic eye movements; evaluate for neuroblastoma)
- Chronic or progressive
 - Developmental defects: Dandy Walker, cerebellar agenesis, rhombencephalosynapsis, Chiari I malformation
 - Ataxic cerebral palsy
 - Tumors

- Paraneoplastic
- Metabolic/degenerative
 - With pathologic accumulation: hexosaminidase deficiency, Niemann-Pick type C, metachromatic leukodystrophy, Wilson disease
 - Hypomyelinating leukodystrophies (e.g., Pelizaeus-Merzbacher disease)
 - SCAs
 - AR ataxias including FRDA (associated pes cavus, cardiomyopathy, diabetes, polyneuropathy), ataxia telangiectasia (frequent infections, increased susceptibility to leukemia/lymphoma; telangiectasias are a late finding, check alpha fetoprotein [AFP] level, sensitive after 1 year of age)
- Recurrent
 - Migraine (vestibular migraine can present with ataxia and vertigo without headache)
 - Episodic ataxia (EA1 and EA2 best characterized, at least 6 loci identified)
 - Metabolic disorders: mitochondrial disorders, Hartnup disease, urea cycle defects, intermittent forms of maple syrup urine disease

DIAGNOSIS

HISTORY

- Focus on the time course of onset.
- Elicit possible ingestions, access to medications at homes of friends, family
- Antecedent infections or vaccinations (fever, especially upper respiratory infection [URI] and GI symptoms)
- Recent trauma (concussion, possible vertebral artery dissection)
- Past medical history: similar episodes, migraines, congenital heart defect, multiple organ system involvement suggestive of metabolic/mitochondrial disease, unusual susceptibility to infection
- Family history: recurrent or progressive ataxias, migraines
- Symptoms to elicit: altered mental status, headache, diplopia, vertigo

(illusion of movement or dizziness), history of seizure, nausea/vomiting, diminished hearing, or tinnitus

PHYSICAL EXAM

- Vital signs: presence of fever
- General exam: presence of meningismus, otoscopic examination for otitis, assess for pharyngitis, lymphadenopathy, splenomegaly, rash, skin and eyes for telangiectasias
- Neurologic exam
 - Mental status: altered with ingestions, CNS infections, ADEM
 - Cranial nerves: funduscopic exam for papilledema, eye movement abnormalities, presence of nystagmus, head impulse (thrust) test for vestibular function, hearing with tuning fork (Weber and Rinne tests), dysarthria or scanning speech
 - Motor: presence of hypotonia or tremor, exclude weakness as cause of incoordination
 - Reflexes: absence suggestive of GBS
 - Sensory: assess for sensory ataxia due to lack of proprioceptive input
 - Coordination: presence of head titubation, truncal ataxia, intention tremor, and limb dysmetria with finger-nose-finger, overshoot with finger-chase, dysdiadochokinesia with rapid alternating movements, heel to shin test
 - Gait: ability to tandem walk, sway with Romberg test (either cerebellar or proprioceptive defect)

DIAGNOSTIC TESTS & INTERPRETATION

Labs

- Initial ER screening labs for acute presentation:
 - CBC, comprehensive metabolic panel (CMP)
 - Lactate, ammonia
 - Toxicology screen and drug levels for specific intoxications
- Additional investigations for chronic/progressive ataxias:
 - Rule out reversible/potentially treatable causes:
 - Exposures: heavy metals, zinc (chelates copper)
 - Autoimmune: celiac, anti-glutamic acid decarboxylase (GAD),

paraneoplastic panel, urine homovanillic acid/vanillylmandelic acid (HVA/VMA) for neuroblastoma

- ▣ Metabolic: TSH, vitamin E, coenzyme Q, B₁₂ and B₁ levels, copper, ceruloplasmin, lactate, ammonia, plasma amino acids, urine organic acids, urine amino acids (for Hartnup disease), very-long-chain fatty acid (VLCFA) with phytanic acid (Refsum), paired CSF and serum glucose levels or SLC2A1 sequencing for GLUT1 deficiency, cholestanol (cerebrotendinous xanthomatosis), lysosomal enzymes
- Other potential screening laboratories: lipid panel, IgA levels, AFP
- Ataxia panels for inherited cerebellar ataxias (e.g., SCAs); most not clinically distinguishable in early stages

Imaging

- Head CT in the acute setting for altered mental status or concern for hemorrhage
- MRI of brain more sensitive in assessing posterior fossa pathology; consider administration of contrast if concern for infection/demyelination; MRA of brain and neck if concern for stroke/dissection.

Diagnostic Procedures/Other

- Lumbar puncture
 - For infection or ADEM: cell counts, protein, glucose, bacterial culture and viral polymerase chain reactions (PCRs), IgG index, oligoclonal bands
 - For suspected metabolic disorders: glucose, protein, cell counts, lactate, pyruvate, 5-methyltetrahydrofolate (MTHF), amino acids; pair with serum glucose and amino acids
- Metaiodobenzylguanidine (MIBG) scan and body CT for potential neuroblastoma
- Nerve conduction studies: suspected GBS
- Electronystagmography (ENG) for potential vestibular involvement
- EEG for consideration of epileptic ataxia

DIFFERENTIAL DIAGNOSIS

- Movement disorders: tremor, chorea, athetosis may be mistaken for

ataxia

- Weakness: incoordination in proportion to weakness (myasthenia gravis, GBS)
- Conversion disorder: variability, distractibility, lack of associated cerebellar signs, astasia-abasia (exaggerated factitious inability to walk or stand)
- Epileptic ataxia (pseudoataxia): episodic, associated alteration of awareness
- Optic ataxia: difficulty reaching for target due to lesions in posterior parietal lobe resulting in impaired visual input to cerebellum

TREATMENT

- Treatment of many of the acute ataxias (ingestions, postviral) is supportive.
- Specific therapies
 - ADEM: steroids
 - GBS: intravenous immunoglobulin (IVIG), plasmapheresis
 - Paraneoplastic: treatment of malignancy, immunosuppression
 - Migraine: avoidance of food triggers, preventive medications (e.g., calcium channel blockers, tricyclic antidepressants [TCAs])
 - Episodic ataxias: acetazolamide
 - Inherited ataxias: some evidence for use of medications such as amantadine, riluzole, varenicline
 - Possible role for treatment with specific vitamins and cofactors (carnitine, coenzyme Q, vitamin E, riboflavin, folinic acid) for mitochondrial disorders

ONGOING CARE

PROGNOSIS

- Most acute ataxias are ingestions and postviral and have a good prognosis. If recovery from a presumed postviral ataxia is delayed (more than 2 weeks), evaluation for neuroblastoma should be

undertaken.

- Recovery from GBS is generally good but can be incomplete.
- Specific diagnosis of an inherited cerebellar ataxia is helpful in predicting clinical course (time to wheelchair, potential for cognitive decline, death).

COMPLICATIONS

- Risk of injury due to falls
- Risk of aspiration due to swallow dysfunction
- Autonomic instability can be associated with GBS.
- With inherited cerebellar ataxias: Some patients also develop neuropathy, spasticity, and cognitive decline.
- Risk of depression and cognitive impairment given increasingly recognized role of cerebellum in cognition and emotion

CODES

ICD10

- R27.0 Ataxia, unspecified
- G11.9 Hereditary ataxia, unspecified
- G11.1 Early-onset cerebellar ataxia

FAQ

- Q: Which ingestions are most likely to cause ataxia?
- A: Alcohol, anticonvulsants, antihistamines, benzodiazepines, TCAs
- Q: What is the typical time course of postinfectious ataxia?
- A: Typically, it will be maximal in onset in the first day or two, then improve within 2 weeks. Ataxia persisting beyond 2 weeks should prompt evaluation for neuroblastoma.
- Q: What is the role of physical therapy for cerebellar ataxia?
- A: Studies have demonstrated that intensive coordination training improves motor performance in progressive cerebellar disorders and translates into improved activities of daily living.
- Q: What is the risk of transmitting a hereditary cerebellar ataxia?
- A: It depends of the mode of inheritance: AR (25%), autosomal dominant (50%, with risk of anticipation for disorders with polyglutamine expansion), maternal (mitochondrial and X-linked disorders).

ATELECTASIS

Richard M. Kravitz

BASICS

DESCRIPTION

- State of collapsed and airless alveoli
- May be subsegmental, segmental, or lobar or may involve the entire lung
- A radiographic sign of an underlying disease and not a diagnosis unto itself

EPIDEMIOLOGY

- Depends on the underlying disease causing atelectasis
- Resorption atelectasis is the most common form.

RISK FACTORS

Genetics

Depends on the underlying disease causing atelectasis (i.e., cystic fibrosis, primary ciliary dyskinesia)

GENERAL PREVENTION

- Maintaining adequate cough
- Good airway clearance techniques in patients at risk for atelectasis

PATHOPHYSIOLOGY

- Reduced lung compliance
- Loss of alveoli (if extensive) may lead to hypoxia.
- Intrapulmonary shunting develops from hypoxia-induced pulmonary arterial vasoconstriction, which may lead to areas of ventilation–perfusion (V/Q) mismatch and further hypoxia.
- If atelectasis is extensive and long-term, pulmonary hypertension may develop.
- Atelectatic areas are prone to bacterial overgrowth and possible secondary infection.

ETIOLOGY

- Airway obstruction (resorption atelectasis)
 - Most common cause of atelectasis in children
 - Obstructed communication between alveoli and trachea
- Large airway obstruction
 - Intrinsic
 - Foreign body aspiration
 - Mucous plug
 - Tumor
 - Plastic bronchitis
 - Extrinsic
 - Hilar adenopathy
 - Mediastinal mass
 - Congenital lung malformations
- Small airway obstruction
 - Acute infection
 - Bronchiolitis
 - Pneumonia
 - Respiratory infections are the most common cause of acute atelectasis
 - Altered mucociliary clearance:
 - CNS depression
 - Smoke inhalation
 - Pain
- Mechanical compression of the pulmonary parenchyma or pleural space (compressive atelectasis)
 - Intrathoracic compression
 - Pneumothorax
 - Pleural effusion
 - Lobar emphysema
 - Intrathoracic tumors
 - Cardiomegaly
 - Diaphragmatic hernias
 - Abdominal distention
 - Large intra-abdominal tumors

- Hepatosplenomegaly
 - Massive ascites
 - Morbid obesity
- Decreased surface tension in the small airways and alveoli (adhesive atelectasis)
 - Stems from surfactant deficiency
 - Diffuse surfactant deficiency
 - Hyaline membrane disease
 - Acute respiratory distress syndrome
 - Smoke inhalation
 - Localized surfactant deficiency
 - Acute radiation pneumonitis
 - Pulmonary embolism
- Neuromuscular weakness (hypoventilation)
 - Inherent weakness
 - Duchenne muscular dystrophy
 - Spinal muscular atrophy
 - Paralysis
 - Acquired weakness (e.g., postanesthesia hypoventilation)

DIAGNOSIS

HISTORY

- Depends on the underlying disease process
- May be asymptomatic
- Cough and/or wheeze can be present.
- Dyspnea
- Chest pain
- Special questions:
 - Is the atelectasis acute, recurrent, or chronic in terms of its duration?
 - Is there a history of asthma, chronic lung disease, or exposure to smoke or toxic fumes that would increase the risk for atelectasis?

PHYSICAL EXAM

- May be normal

- Tachypnea
- Rales or rhonchi
- The most specific sign is localized decrease or loss of breath sounds.
- Dullness to percussion if large area involved
- Tracheal deviation and shift of heart sounds toward atelectatic side
- Localized wheezes in cases of partial obstruction
- Cyanosis (seen when extensive atelectasis is present, causing impairment of oxygenation and areas of ventilation/perfusion mismatch)

DIAGNOSTIC TESTS & INTERPRETATION

Lab

Appropriate test depends on the underlying etiology:

- Asthma
 - Spirometry
 - Sweat test (if cystic fibrosis suspected)
- Infection
 - Cultures (sputum, blood, bronchoalveolar lavage fluid)
 - Nasal washing (especially for viruses)
 - PPD (when tuberculosis is suspected)
- Foreign body aspiration
 - Bronchoscopy (to remove the obstructing agent. Rigid bronchoscopy is indicated if the obstructing agent is a foreign body; flexible: can be used for mucous plugs, plastic bronchitis, or infectious etiology)
- Immunodeficiency
 - CBC with differential
 - Immunoglobulins (IgG, IgA, IgM)
 - HIV testing
- Congenital malformations
 - CT scan of the chest (for lung malformation)
 - Bronchoscopy (for H-type tracheoesophageal fistula [TEF] or bronchial stenosis)

Imaging

- Chest radiograph

- Most important diagnostic tool
- Radiographic signs of atelectasis:
 - ▣ Loss of lung volume from the affected lobe
 - ▣ Compensatory hyperexpansion of the remaining lobes on the affected side
 - ▣ Shift of interlobar fissures
 - ▣ Elevation of diaphragm
 - ▣ Mediastinal shift toward the affected side
 - ▣ Approximation of ribs on the affected side
- CT of chest
 - Confluence of bronchi and blood vessels converge toward the affected side.
 - Provides information regarding precise location and extent of any obstructing process

DIFFERENTIAL DIAGNOSIS

- Pneumonia
 - Viral pneumonia versus subsegmental atelectasis
 - Bacterial pneumonia versus segmental or lobar atelectasis
- Thymus (may often be mistaken for atelectasis in an upper lobe)
- Congenital malformations (e.g., sequestration, bronchogenic cyst)
- Pleural effusion
- Asthma (acute exacerbation or poorly controlled)

TREATMENT

GENERAL MEASURES

- Treat underlying disease (i.e., removal of aspirated foreign body, clearance of mucous plugs, treatment of any underlying infection)
- Chest physical therapy with bronchodilators (usually for at least 1 month)
- If no improvement with conservative therapy, a bronchoscopy with lavage to remove possible mucous plug is indicated (lavage may be with saline or, in select cases, with recombinant human DNase, N-acetylcysteine, or hypertonic saline).

- Consider surgery to remove the affected region:
 - Chronic or recurrent atelectasis
 - Unresponsive to therapy
 - Focal bronchiectasis has developed.
 - Significant morbidity is seen.
- Prevention of recurrent or future atelectasis: directed toward underlying cause, when applicable
- Airway clearance is important in clearing areas of atelectasis.
- Various techniques are available including the following:
 - Manuel chest physiotherapy
 - Mechanical chest physiotherapy (ThAIRapy vest)
 - Incentive spirometry
 - Acapella or Flutter devices
 - Intermittent positive pressure breathing (IPPB) or intrapulmonary percussive ventilator (IPV)
 - Mechanical insufflator–exsufflator (Cough Assist):
 - For patients with weakened cough (i.e., neuromuscular weakness)

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

Expect improvement: 1–3 months in typical, uncomplicated cases

PROGNOSIS

- Depends on the underlying disease process
- In otherwise healthy individuals: excellent

COMPLICATIONS

- Recurrent infections
- Bronchiectasis
- Hemoptysis
- Abscess formation
- Fibrosis of the pulmonary parenchyma

CODES

ICD10

- J98.11 Atelectasis
- P28.10 Unspecified atelectasis of newborn
- P28.0 Primary atelectasis of newborn

FAQ

- Q: What should be considered if atelectasis is recurrent in nature but in different segments?
- A: Asthma should always be considered if atelectasis is recurrent and in varying segments.
- Q: When is the optimal time for bronchoscopy?
- A: There are no established criteria for when a bronchoscopy should be performed. A bronchoscopy should be done early in the course of illness when:
 - There is a high suspicion of a foreign body
 - Significant respiratory distress is present
 - Cases of acute chest syndrome in patients with sickle cell disease
 - The atelectasis is extensive and conservative treatment is ineffective
 - Bronchoscopy is infrequently performed in patients with cystic fibrosis secondary to its recurrent nature.

ATOPIC DERMATITIS

Rhonique Shields-Harris • Marceé J. White

BASICS

DESCRIPTION

Atopic dermatitis or eczema is a chronic skin condition characterized by an acute, intermittent pruritic rash. It most commonly begins in infancy or early childhood with an age-specific pattern of skin involvement.

Individuals with atopic dermatitis usually have a personal or family history of atopy (e.g., asthma, hay fever, or rhinitis).

EPIDEMIOLOGY

- Common, occurs in nearly 1 in 5 children
- 60% of affected children will develop atopic dermatitis in the 1st year of life and 85% by age 5 years.
- Higher prevalence in Nevada, Utah, Idaho, and East Coast states
- Higher prevalence in urban versus rural areas
- Usually worse in the winter, but flares can occur at any time of year

RISK FACTORS

Genetics

- Genetic predisposition in affected patients with 30–70% of family members having atopy (allergies, asthma, eczema)
- Mode of inheritance is not well defined and is likely multifactorial.
- Studies show that genetic mutations in the filaggrin gene (FLG) are associated with skin barrier defects and occur in early-onset atopic dermatitis.

PATHOPHYSIOLOGY

- Histologic findings depend on the stage of atopic dermatitis (i.e., acute or chronic).
- Atopic dermatitis is a disorder of immune dysregulation with increased T-cell activation and increased cytokine production of interleukin (IL)-4, IL-5, and IL-13, which lead to increased IgE production.

- Acute atopic dermatitis shows spongiosis, a manifestation of intercellular edema that can lead to vesicle formation.
- Mutations in the filaggrin gene (FLG) are associated with abnormal skin barrier function and cause increased transepidermal water loss and increased penetration of allergens.

ETIOLOGY

- Etiology of atopic dermatitis is multifactorial, with genetic, environmental, physiologic, and immunologic factors.
- Increased viral (warts and molluscum) and dermatophyte infections seen in atopic patients appear to be related to cytokine-induced suppression of endogenous antimicrobial peptides.
- Patients often have elevated IgE levels and decreased chemotaxis of neutrophils.

DIAGNOSIS

HISTORY

- Age of onset
- Location of skin findings
- Pruritus
- Prior treatment
- Bathing habits
- Family history of atopy (allergies)
- Asthma
- Allergic rhinitis
- Exposure to allergens (i.e., change in detergents/soaps, excessive dryness)

PHYSICAL EXAM

- Acute flares reveal erythematous and scaly maculopapular exudative patches.
- Chronic disease is characterized by hyperpigmentation or hypopigmentation, lichenification, and scaling.
- Age-specific patterns of skin involvement:
 - In infancy, atopic dermatitis is widespread, primarily affecting

- extensor surfaces and also involves the cheeks, forehead, and scalp.
- In childhood, the disease affects the characteristic flexural sites with lichenification. The hands and face can also be involved.
- From adolescence to adulthood, the flexures, neck, hands, and feet are primarily involved.
- Severe atopic dermatitis can present as exfoliative erythroderma with diffuse scaling and erythema.
- Other associated findings include Dennie-Morgan folds (infraorbital folds), pityriasis alba (dry white patches), hyperlinear palms, facial pallor, infraorbital darkening, follicular accentuation, keratosis pilaris (dry, rough hair follicles on extensor surfaces of upper arms and thighs), and ichthyosis.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- There are no diagnostic tests for atopic dermatitis.
- Biopsy can be helpful to rule out other skin disorders, such as psoriasis.
- IgE levels can be elevated but need not be checked.
- Bacterial cultures of skin can be obtained to rule out superinfections.
- Rapid fluorescent antibody studies, polymerase chain reaction studies, or viral cultures and Tzanck smear can identify the presence of eczema herpeticum.

DIFFERENTIAL DIAGNOSIS

- Tinea corporis
- Severe seborrheic dermatitis
- Contact dermatitis
- Allergic or irritant psoriasis
- Wiskott-Aldrich syndrome
- Langerhans cell histiocytosis
- Acrodermatitis enteropathica
- Scabies
- Xerosis
- Hyper-IgE syndrome
- Metabolic deficiencies
 - Carboxylase deficiencies

- Prolidase deficiencies

TREATMENT

MEDICATION

- Topical steroids
 - Mainstay of therapy to control inflammation
 - Mid- to high-potency steroids are used during acute flares, with tapering to milder potency steroids when control is achieved.
 - Long-term use of steroids can lead to atrophy, telangiectasias, and tachyphylaxis
- Oral antihistamines, such as hydroxyzine or diphenhydramine, may help to decrease itching in selected patients.
- Oral antibiotics
 - Indicated when there is superinfection of lesions
- Oral antivirals are indicated in cases of eczema herpeticum.
- Topical calcineurin inhibitors (TCIs)
 - Include tacrolimus ointment and pimecrolimus cream
 - Approved for use in children 2 years of age and older
 - These topical agents act to suppress T-cell function.
 - Sun damage can be potentiated, so children who receive these medications should receive instructions for diligent sun protection and sunscreen use.
- Systemic steroids are generally not used because of the chronicity of atopic dermatitis. They are reserved for refractory atopic dermatitis, and if used, it should only be for a short duration.
- Phototherapy with UVB can be used in patients with extensive disease resistant to other therapies.
- Topical barrier repair agents including N-palmitoylethanolamine cream, MAS063DP cream, and various ceramide formulations may be useful adjuncts to therapy.

ADDITIONAL TREATMENT

General Measures

- There is no cure for atopic dermatitis.

- Parents must understand that this is a chronic disease with intermittent flares and that control is the aim of treatment.
- Good skin care is critical to maintenance and includes use of mild soaps, frequent use of emollients, and wet wraps.
- Dilute bleach baths (about 1/4 cup per full tub of water or about 1 tsp per gallon of water) can be used as a once- or twice-weekly 10-minute soak to help reduce bacterial skin colonization and risk for recurrent skin infection.
- Avoidance of environmental irritants is recommended. Nail trimming and protective clothing at night to avoid scratching while sleeping is also helpful.
- Vitamin D supplementation has been shown to decrease the severity of atopic dermatitis due to effects on immunomodulation

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- It should be emphasized to parents that atopic dermatitis is a chronic disease and that good skin care is necessary to control disease activity and enhance quality of life.
- To improve compliance with treatment, providers should use therapeutic patient education techniques so parents and patients can manage this chronic disease.
- Address parental concerns about the safety of topical steroids in order to reduce steroid phobia.

PROGNOSIS

Up to 40–50% of children will outgrow their atopic dermatitis after the age of 5 years.

COMPLICATIONS

- Skin infections
 - Decreased cell-mediated immunity, decreased chemotaxis, and decreased production of endogenous antimicrobial peptides can result in increased infection (e.g., viral, dermatophyte, bacterial).

- Patients with atopic dermatitis have a high density of *Staphylococcus aureus* on their skin, and given the fissures and open excoriations, there is a risk of superinfection.
- Eczema herpeticum
 - The decreased integrity of the skin can result in widely spread cutaneous infections such as herpes simplex infection, known as Kaposi varicelliform eruption or eczema herpeticum.
 - Similar problems can also be seen with coxsackievirus or molluscum contagiosum and used to occur with vaccinia.
- Overuse of topical medications
 - Overuse of potent topical steroids can result in hypopigmentation, telangiectasias, atrophy, and striae as well as excess systemic absorption leading to hypothalamic–pituitary axis suppression and growth retardation.
 - Pigmentary changes may result from overuse of topical medications; however, the lesions of atopic dermatitis may themselves cause postinflammatory skin color changes independent of topical therapy.
- Early growth delay is not uncommon among children with atopic dermatitis, although later catch-up growth is generally seen. This may be related to various mechanisms including impaired growth hormone release. Growth delay can occur independent of topical steroid exposure.
- Increased prevalence of emotional, behavioral, and psychological issues secondary to sleep disturbance in patients with atopic dermatitis

CODES

ICD10

- L20.9 Atopic dermatitis, unspecified
- L20.83 Infantile (acute) (chronic) eczema
- L20.89 Other atopic dermatitis

FAQ

- Q: Will the child outgrow this?
- A: Up to 40–50% of children will outgrow their atopic dermatitis after age 5 years. In some patients, however, the disease will persist to varying degrees throughout adulthood.
- Q: Will the steroid treatment change my child's skin color?
- A: Skin pigment changes are caused primarily by the lesions of atopic dermatitis, which cause postinflammatory hyper- or hypopigmentation (darkening or lightening), independent of topical therapy. The discoloration will eventually fade but may take weeks or months.
- Q: When atopic dermatitis is controlled, is any treatment necessary?
- A: Excessive dryness can exacerbate or flare disease. Therefore, less frequent use of soaps and frequent use of emollients are recommended.
- Q: Do food hypersensitivities play a role in atopic dermatitis?

- A: This is a debated issue. In general, the majority of patients are probably not adversely affected by foods. However, some individuals, particularly those who are unresponsive to routine therapy, may benefit from screening for food hypersensitivity and a trial of avoidance to any foods that test positive. The most common foods associated with exacerbation when an association can be made are eggs, milk, wheat, soy, peanuts, and fish.

ATRIAL SEPTAL DEFECT

Jonathan Fleenor

BASICS

DESCRIPTION

- An opening in the atrial septum, other than a patent foramen ovale (PFO)
- 4 major types of atrial septal defects (ASDs)
 - Secundum ASD
 - Primum ASD
 - Sinus venosus ASD
 - Coronary sinus ASD
- A PFO usually does not cause a significant intracardiac shunt. A probe-patent PFO can be found in up to 15–25% of normal hearts at pathologic exam.
- Secundum defects make up 60–70% of all ASDs. Usually, there is a shunt from the left atrium to the right atrium.
- Primum defects occur in ~30% of all ASDs. They are usually associated with a cleft mitral valve. This defect is the result of an abnormality of the endocardial cushions and therefore is also referred to as an incomplete atrioventricular (AV) canal defect.
- Sinus venosus defects can be of the superior or inferior vena caval type and occur in ~5–10% of all ASDs. In ASDs of the superior vena caval type, the right pulmonary veins (usually right upper lobe) may drain anomalously to the superior vena cava or right atrium.
- Coronary sinus ASDs are rare and occur in <1% of all ASDs. They are often associated with absence of the coronary sinus and a persistent left superior vena cava that joins the roof of the left atrium (also known as an “unroofed coronary sinus”).

EPIDEMIOLOGY

Females > males (2:1)

Incidence

- Difficult to determine
- Represents 6–10% of all cardiac anomalies encountered

PATHOPHYSIOLOGY

- A left-to-right shunt occurs through the ASD. For large defects, this results in right atrial and right ventricular volume overload.
- There is usually increased pulmonary blood flow.
- The left-to-right shunt generally increases with time as pulmonary resistance drops and right ventricular compliance normalizes.
- Moderate and large defects are associated with a Qp/Qs ratio of >2:1.
- The direction of atrial shunting is determined by the relative compliance of the right and left ventricles.

ETIOLOGY

- ASDs may be associated with partial or total anomalous pulmonary venous drainage, mitral valve anomalies, transposition of the great arteries, or tricuspid atresia.
- Although usually isolated, ASDs may occur as part of a syndrome (Holt-Oram [autosomal dominant]).

DIAGNOSIS

HISTORY

- Most infants are asymptomatic.
- Older children with moderate left-to-right shunts are often asymptomatic but may have mild fatigue or dyspnea, especially with exercise.
- Children with large left-to-right shunts may complain of fatigue and dyspnea, which may become noticeable as the child gets older.
- Growth failure is uncommon.
- Older patients with large atrial shunts may develop atrial arrhythmias.

PHYSICAL EXAM

- Inspection and palpation of the precordium are usually normal, although older children with a large ASD may have a hyperdynamic precordium, right ventricular heave, or precordial bulge.

- Auscultation reveals 3 important features:
 - Wide and “fixed” splitting of S_2 . Splitting of S_2 (A_2 and P_2 components) is caused by a delay in emptying of a volume-loaded right ventricle.
 - A systolic ejection murmur at the upper left sternal border. This murmur is caused by an increase in blood flow across a normal pulmonary valve. It may be differentiated from the murmur of pulmonary stenosis because there is no click.
 - A diastolic murmur at the lower sternal border, indicating a Q_p/Q_s ratio of at least 2:1. This murmur is caused by increased flow across the tricuspid valve.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- ECG
 - Usually normal sinus rhythm with an rSR' (incomplete right bundle branch block pattern) in leads V_1 , V_3R , and V_4R , indicating right ventricular volume overload. For larger shunts, ECG may show evidence of right atrial enlargement as well as 1st-degree AV block. A late finding suggestive of pulmonary hypertension is right ventricular hypertrophy.
- Chest radiograph
 - Cardiomegaly (right atrium and right ventricle), increased pulmonary vascular markings, and a dilated pulmonary trunk are seen in patients with significant left-to-right shunts.
- Echocardiogram
 - A 2-D echo study is diagnostic; it reveals the location, size, and associated defects, if any. It may demonstrate dilated right heart structures. Color Doppler generally permits visualization of the direction of shunt flow. Older children and adolescents may require transesophageal echo to best define the ASD.
- Cardiac catheterization
 - Generally unnecessary. It is indicated when pulmonary vascular disease is suspected (determination of pulmonary vascular resistance) or for associated cardiac defects.

DIFFERENTIAL DIAGNOSIS

- Ventricular septal defect
- Patent ductus arteriosus
- AV canal defect
- Valvar pulmonary stenosis

TREATMENT

ADDITIONAL TREATMENT

General Measures

- Infants with congestive heart failure should be treated with diuretics.
- Elective closure is indicated for ASDs associated with large left-to-right shunts, cardiomegaly, or symptoms.
 - The timing of closure is usually deferred until 3–5 years of age.
 - For most secundum-type ASDs, device closure of the defect can be performed in the cardiac catheterization laboratory, thus avoiding surgery.
- Prevention of paradoxical emboli and cerebrovascular accidents is an uncommon but possible indication for closure of ASDs or PFO.
- Irreversible pulmonary hypertension from a long-term left-to-right shunt usually does not occur until adolescence or young adulthood.
- Sinus venosus, primum, and coronary sinus–type ASDs require surgical closure. The mortality of surgical repair for an uncomplicated ASD approaches 0%.
- There is some anecdotal evidence suggesting that PFOs are a cause of migraine headaches in certain populations. Prospective adult studies are currently ongoing to further investigate this question, but to date no study has found an indication for PFO closure in migraine patients.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Children with typical auscultation, chest radiograph, and ECG findings

should undergo an echocardiographic evaluation to determine the location and size of the ASD.

- Children with ASDs should have regular follow-up to assess for signs of congestive heart failure or right ventricular volume overload. Restriction of activity is unnecessary. Subacute bacterial endocarditis (SBE) prophylaxis is not indicated for an isolated secundum ASD. Residual ASD after surgery is rare.
- SBE prophylaxis is indicated for the first 6 months (assuming no residual defect) after closure of a secundum defect.
- Complications related to surgery include the following:
 - Sinus node dysfunction
 - Venous obstruction (facial or pulmonary edema) may occur after a sinus venosus ASD repair.
 - Postpericardiotomy syndrome, which manifests with nausea, vomiting, chest pain, abdominal pain, or fever, may occur a few weeks after surgical repair. Although a friction rub may not be present, the chest radiograph may show cardiomegaly and the echocardiogram may reveal a pericardial effusion.

PROGNOSIS

- The prognosis for small ASDs seems excellent without specific therapy.
- Spontaneous closure of small secundum ASDs can occur in up to 80% of infants in the 1st year of life. Isolated secundum ASDs of moderate and large size do not typically cause symptoms in most infants and children.
- Pulmonary hypertension is rare in childhood.
- Atrial flutter and fibrillation occur in up to 13% of unoperated patients older than 40 years of age.
- Bacterial endocarditis is rare in children with isolated ASD.
- Paradoxical emboli may occur and should be considered in patients with cerebral or systemic emboli.

CODES

ICD10

- Q21.1 Atrial septal defect
- Q21.2 Atrioventricular septal defect

FAQ

- Q: When should a moderate secundum ASD be closed?
- A: This can generally be electively performed in children prior to their starting grade school.
- Q: What is the significance of a patient having gastrointestinal complaints (nausea and vomiting) 2–3 weeks after surgical closure of an ASD?
- A: This may represent a pericardial effusion (postpericardiotomy syndrome).

ATTENTION-DEFICIT/HYPERACTIVITY DISORDER

D. David O'Banion • Mark Wolraich

BASICS

DESCRIPTION

- Attention-deficit/hyperactivity disorder (ADHD) is a chronic condition that is characterized by a pattern of developmentally inappropriate behaviors of inattention and/or hyperactivity/impulsivity.
- DSM-5 criteria for diagnosis:
 - At least 6 of 9 behaviors in inattention and/or 6 of 9 hyperactivity/impulsivity behaviors and
 - Maladaptive behaviors persisting for at least 6 months and
 - Impairment from symptoms present in 2 or more major settings (home, school, day care, after-school activities) and
 - Some symptoms existed before age 12 years.
- It can be classified into 3 subtypes:
 - Hyperactive/impulsive
 - Inattentive
 - Combined type
- Symptoms cannot be better explained by another mental health disorder. Autism spectrum disorder is no longer an exclusion criteria.

EPIDEMIOLOGY

- 2:1 males-to-female ratio
- 3–10% prevalence of school-age children
- Females more likely to have inattentive type

RISK FACTORS

Genetics

- Risk of ADHD in 1st-degree relatives is ~25%.
- Concordance in monozygotic twins: 59–81%; dizygotic twins: 33%

COMMONLY ASSOCIATED CONDITIONS

- Learning disorders
- Language disorders
- Anxiety disorder
- Mood disorders
- Sleep disorders
- Tic disorder (may affect treatment decisions)
- Oppositional defiant disorder and conduct disorder
- Poor social skills

DIAGNOSIS

- Primary care clinicians should consider an extended visit to evaluate any child, age 4–18 years, presenting with behavioral and/or academic problems related to ADHD symptoms.
- To make the diagnosis, the clinician should ensure DSM-5 criteria are met and document impairments in >1 major setting (e.g., home, school, day care). Information should be gathered from more than one reporter, when possible (e.g., caregivers and teachers).
- Comorbid conditions may prompt a referral to a subspecialist.
- In general, the diagnosis does not require any specific psychological test, cardiac test, laboratory test, or referral.
- Watchful waiting is not recommended, as evidence-based treatments can make significant improvements even at a young age.

HISTORY

- A detailed history of the child’s behavior at home, school, and with peers
- Onset and duration of noted behaviors—sudden onset should prompt consideration of other conditions (mood disorder, trauma, abuse, substance use, etc.).
- Timing of behaviors with respect to developmentally appropriate expectations placed on the child
- Frequent or excessive need of supervision and redirection in age-appropriate common tasks and routines
- Not following rules/requests—oppositional and/or “forgetful” (getting

lost or side-tracked)

- Academic progress with particular attention to academic problems with specific subjects, and behaviors during specific subjects
- Disruption of peer relationships
- Developmental history (developmental delay is not characteristic of ADHD)
- Sleep history—adequate length, hygiene
- Participation in age-appropriate organized activities (e.g., scouts, camp, team sports)
- Family history of dropping out of school, ADHD, or learning disorders
- Family history of early cardiac disease including arrhythmias, hypertrophic cardiomyopathy, sudden cardiac death or unexpected death in children or young adults
- Social history: those who live with patient, recent family discord, separation, recent death in the family, recent change in schools
- Past medical history and medication history
- Adverse pregnancy or birth history

ALERT

Ability to concentrate for hours on video games is not reassuring but commonly reported.

PHYSICAL EXAM

- Comprehensive physical and neurologic examination with attention to specific systems based on the history
- Vital signs: weight, height, pulse, BP, visual and hearing acuity
- Note any dysmorphism.

DIAGNOSTIC TESTS & INTERPRETATION

- Validated rating scales of behavior help the clinician review DSM-5 criteria. After the initial concern is raised, these can be distributed, collected, and reviewed prior to a scheduled evaluation.
 - Connor Rating Scales-Revised, Vanderbilt ADHD Rating Scales, SNAP, ADHD RS
 - Ideally, collect rating scales from parents and teachers.
 - Some assess only for ADHD; others include assessment of comorbidities such as anxiety, oppositional defiant disorder, and

depression (Vanderbilt).

- Most clinicians choose a single tool and gain familiarity with it.
- Most scales are useful to measure change with treatment.
- Some are proprietary (Conner), and some are freely distributed (Vanderbilt).
- IQ and achievement testing
 - Not required but should be guided by specific concerns for disabilities
 - An evaluation for an Individual Educational Program (IEP) or 504 plan may be obtained following parental written request to the child's school.

Lab

Not required except as guided by history and physical. Screening ECGs are not recommended or considered cost-effective.

DIFFERENTIAL DIAGNOSIS

- Developmental
 - Learning disabilities
 - Intellectual disability
 - Autism spectrum disorder
 - Language or speech disorder
- Psychiatric
 - Anxiety disorders
 - Depression
 - Obsessive-compulsive disorder
 - Oppositional defiant disorder or conduct disorder
 - Adjustment disorder
- Medical
 - Genetic disorder
 - Sleep disorder
 - Sensory impairment (vision, hearing)
 - Medication side effects
 - Toxins (lead)
 - Iron deficiency anemia
 - Postconcussion syndrome

- Educational
 - Inappropriate school environment
 - Developmentally inappropriate expectations
- Social
 - Disorganized/chaotic family environment
 - Child abuse and neglect or sexual abuse
 - Psychosocial stressors

TREATMENT

GENERAL MEASURES

- Treat ADHD as a chronic disease and use the medical home model. Partner and discuss treatment options with families. Include the school when possible.
- The family and patient choose target goals and actively participate in measuring/monitoring achievement of these goals.
- 3 treatment modalities:
 - Behavior therapy (evidence based)
 - Educational support
 - Medication

NONPHARMACOLOGIC

- Children 4–5 years: behavior therapy
- Reduces core symptoms of ADHD in multiple settings. Different from interpersonal talk/play therapy, which has not been efficacious in treatment. Parent education, parent training programs, and behavior therapies usually have a planned number of weeks (10–16 weeks). Their focus is increasing positive behavior through rewards and extinguishing negative behavior through ignoring and effective discipline.
- Cognitive behavioral therapy can be helpful for older children and adults.
- Educational support options:
 - Request a 504 Plan through patient's school to evaluate for possible accommodations (different from an IEP).

- Small teacher-to-student ratio is ideal.
- Good communication between school and home (e.g., a daily behavior report card)
- Homework log monitored by teacher and parent
- Psychological support may be helpful for:
 - Patient who has poor peer relations, such as peer groups or social training groups
 - Patient with a comorbidity
 - Commonly, families have difficulty with parenting a child with ADHD.

MEDICATION

Consider family preferences, other family member's reaction to specific medications, duration of coverage (shorter school day in younger child), ability to swallow pills, and concern for divergence (or abuse).

First Line

- **Stimulants:** FDA-approved. All are either methylphenidate or amphetamine-class derivatives.
- **Efficacy:** extensive evidence supporting efficacy and safety. 80% of children with ADHD show significant improvement.
- **Pharmacokinetics:** Individual response is highly variable. Effectiveness and side effects can be seen within hours of starting medication. Duration varies by preparation. Younger children may metabolize stimulants slowly, giving a longer duration than expected for immediate-release preparations. Does not “build up” in the system, so no known permanent effects. Daily dosing therefore necessary for symptom relief
- **Dose:** Weight-based dosing is not appropriate due differences in metabolism and idiosyncratic responses. Start with smallest dose and titrate up in single-dose increments weekly as needed. Base titrations on changes in rating scales and achievement toward target goals, weighing improvements against side effects. Start with short-acting medication in children younger than 7 years. For some younger children, this may provide a sufficient duration of therapy for school. Consider long-acting/extended-release in older children. Start

medication when the parents are available to watch for side effects and duration of action (typically over a weekend). Follow closely with the parents; ask them to get feedback from school on a weekly basis until dose is properly adjusted. This process may take 1–2 months to be completed. If at highest dose and still not having good effect, or having significant side effects at a lower dose, switch to the lowest dose of the other class of stimulants and repeat the titration process.

- **Side effects:** Side effects last less than 24 hours. Families should know that any unacceptable side effects will abate if the medication is stopped. Most side effects can be managed expectantly.
- Decreased appetite is common, although sustained weight loss is not.
- Abdominal pain, tics, headache, difficulty falling asleep, and jitteriness
- Difficulty shifting attention, overfocus (the “zombie effect”) is from too high of a dose.
- Severe movement disorders, obsessive–compulsive thoughts, or psychotic symptoms are rare and cease when medication is stopped.
- Growth velocity may slow. Final adult height is minimally decreased, if at all affected.
- **Contraindications:** glaucoma, symptomatic cardiovascular disease (except with guidance by cardiology), hyperthyroidism, hypertension

Second Line

- Atomoxetine: selective norepinephrine uptake inhibitor. Once-a-day or b.i.d. dosing. Must be taken daily for 4 weeks before effects are at maximum. Similar side-effect profile as stimulants but with increased chance of suicidal thinking. Less evidence for use and less efficacious than stimulants. Start with 0.5 mg/kg/24 h for 1 week, and if no side effects (often GI upset), increase to 1.2 mg/kg/24 h, max 1.4 mg/kg/24 h or 100 mg/24 h if >70 kg.
- Adjuvants: extended-release α -adrenergic agonists (clonidine, guanfacine). Must take daily. Commonly causes sedation that may improve with time

ISSUES FOR REFERRAL

- When comorbidities are suspected, or when contra-indications for treatment are present

- If patient is not responding to titration attempts of both stimulant classes
- If the patient is having difficulty tolerating different stimulants, or having unexpected or severe side effects

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Initially, follow-up by phone may be every 1–2 weeks until proper dosing is achieved. Follow up in clinic in 1 month. After successful titration, patients should be seen every 3–6 months specifically for ADHD visits.
- Consider mailing refills once titrated to prevent burden on families who'd otherwise pick up the paper prescription.
- Monitor weight, height, BP, and heart rate.
- Weight loss is not usually sustained.
- Encourage meals when patient is hungry, perhaps later than family's usual dinner.
- Assess for change in growth velocity.
- Assess family and peer relationship.
- Assess school performance.
- Assess for ongoing need for medication.

CODES

ICD10

- F90.9 Attention-deficit hyperactivity disorder, unspecified type
- F90.1 Attn-defct hyperactivity disorder, predom hyperactive type
- F90.0 Attn-defct hyperactivity disorder, predom inattentive type

FAQ

- Q: What is the role of diet or complementary and alternative medical (CAM) therapies?
- A: Although in the past, it has been thought that certain foods and additives caused ADHD, there are no studies that show changes in diet to be of benefit. Frequently, families will want to explore the use of CAM therapies either in conjunction with or instead of treatment with stimulant medication. If safety can be assured, it may be reasonable for patients to try for a finite period of time if it ultimately helps the patient. If CAM therapy fails, the parents may be more willing to try stimulant medication.
- Q: Is medication needed every day?
- A: This depends on the needs of the patient and type of medication. Some patients need medication daily in order to function successfully with peers or in structured environments, like team sports or weekend schools. Other patients who need help mainly with focusing attention

do well with medication only during learning periods (school days). Some patients will not need medication during the summer holiday or during school breaks.

- Q: How long will my child be on medication?
- A: A large percentage of children with ADHD will continue to have symptoms as adults. Although every patient is different, some patients may need to continue medication through formal learning (high school and college). During this time, they should be able to learn coping strategies to minimize the effects of their symptoms. If treatment goals are being met, it is reasonable to have a trial off medications to see if performance off medications can be sustained (sometimes called a drug holiday).
- Q: Are there support groups available?
- A: An organization that is widely recognized as an advocacy and support group for families is Children and Adults with Attention Deficit/Hyperactivity Disorder (www.chadd.org). Use discretion when using online resources; there are many online Web sites that are sponsored by pharmaceutical companies and others that encourage alternatives to medication and actively discourage use of currently recommended treatments.

AUTISM SPECTRUM DISORDER

Alisson Richards • David C. Rettew

BASICS

DESCRIPTION

- Neurodevelopmental disorder characterized by the following:
 - Delays/impairments in development of social communication and social interaction
 - Restricted, repetitive patterns of behavior, interests, or activities
 - Symptoms present in early childhood
 - Significant impairment in functioning
- Diagnostic criteria changes since 2013:
 - The Diagnostic and Statistical Manual of Mental Disorders 4th edition (DSM-IV) previously included autistic disorder, Asperger disorder, Rett disorder, childhood disintegrative disorder, and pervasive developmental disorder, not otherwise specified within overall category.
 - DSM-5 has eliminated these separate diagnoses due to insufficient evidence.
 - DSM-5 added severity levels (1–3) based on the level of support required.
- Associated with specific and known genetic disorder (e.g., fragile X) in minority of cases
- Behaviors exist along continuum with unclear boundaries between trait and disorder.

EPIDEMIOLOGY

Prevalence

- Approximately 1% of population
- Rate rising over past decades
- 4 times more common in males than females
 - Females are more severely impaired with intellectual disability.

RISK FACTORS/ETIOLOGY

- Strong genetic influence
- Risk in 1st-degree relatives 2–10%
- Multiple genes involved
- Other risk factors: closer spacing of pregnancies, advanced maternal or paternal age, extreme premature birth (<26 weeks), possible maternal inflammation in utero
- Link to vaccinations not supported by scientific evidence
- Cause(s) unknown but may be associated with abnormalities in cortical laminar architecture during prenatal brain development

COMMONLY ASSOCIATED CONDITIONS

- Intellectual disabilities
- Gastrointestinal problems
- Seizure disorders
- Sleep disorders
- Attention problems, anxiety, depression, mood disturbances
- Aggression and self-injury

DIAGNOSIS

Typically, pediatricians are the first point of contact and play an important role in screening and early recognition, followed by more in-depth evaluation with a developmental pediatrician, psychologist, child psychiatrist, or neurologist where assessment and treatment plans can be coordinated with the schools.

HISTORY

- A detailed prenatal, developmental, medical, family, and social history are essential.
- Delays/impairments in social communication and social interaction
 - Delayed language development
 - Impairment in eye contact, facial expression, nonverbal social behaviors (pulling parents by hand but not looking at them)
 - Lack of pointing
 - Impaired social interactions and relationships
 - Lack of imaginary play appropriate to developmental level

- Does not include others in play
- Stereotyped behaviors and restricted interests
 - Stereotypies (e.g., rocking, hand flapping)
 - Echolalia
 - Restricted range of interests/activities
 - Attachment to unusual objects, fascination with parts of objects
 - Behavioral rigidity, distress with changes in routine
 - Hyper- or hyporeactivity to sensory input or unusual sensory interests in objects or persons (smelling, touching, sensitivity to clothing)

PHYSICAL EXAM

- Evaluate for growth disturbance.
- 20–30% have macrocephaly: neurocutaneous disorder, storage disease, hydrocephalus, or no identifiable cause
- Signs of self-injurious behavior
- Stereotypical behavior, involuntary movements, motor coordination abnormalities, mirror/overflow movements
- Ophthalmologic/audiologic evaluations to rule out visual or hearing deficits
- Long, thin face; prominent ears: fragile X (macroorchidism may not be present until after puberty)
- Wood's lamp examination: Neurocutaneous syndromes and hypopigmented macules/fibromas suggest tuberous sclerosis.
- Microcephaly: toxoplasmosis, other viruses, rubella, cytomegalovirus, herpes virus (TORCH) infection; Angelman syndrome; Rett disorder
- Look for spasticity, visual loss, ataxia: leukodystrophy

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Electroencephalogram if epilepsy is suspected (~25%)
- Head MRI/CT: if intellectual or focal neurologic deficit is present or if suspected neurocutaneous disease
- Chromosome studies: if child is intellectually disabled
- Microarray analysis increasingly recommended
- Toxoplasma, other viruses, rubella, cytomegalovirus, herpes virus

titers: setting of microcephaly

- CBC: evaluation of growth delay and/or pica
- Blood lead level: rule out lead intoxication
- Thyroid function tests: rule out hyper-/hypothyroidism
- Audiogram/brainstem auditory evoked response: for children with speech and language delay and to rule out hearing deficits
- Ophthalmologic evaluations to rule out visual deficits

Diagnostic Procedures/Other

- Screening tools
- Modified Checklist for Autism in Toddlers (M-CHAT) with new Revised with Follow-up Version downloadable at http://www2.gsu.edu/~psydlr/M-CHAT/Official_M-CHAT_Website.html
- Social Responsiveness Scale (SRS)
- Autism Diagnostic Observation Schedule (ADOS) and Autism Diagnostic Interview (ADI-R) are structured interviews and assessments usually performed by a psychologist, developmental pediatrician, psychiatrist, or neurologist: considered the gold standard

DIFFERENTIAL DIAGNOSIS

- Intellectual impairment: MAY not have autistic spectrum disorder if communication, behavior, play, and social skills appropriate to developmental age
- Social (pragmatic) communication disorder: lack of restricted, repetitive patterns of behavior or interests
- Rett syndrome: females; hand washing/hand-wringing movements, head growth deceleration before 48 months of age, MeCP2 gene
- Deafness: delayed/absent oral language acquisition; behavioral/social difficulties may relate to language delays.
- Language disorder: no deficits in social interactions or restricted range of interests
- Landau-Kleffner syndrome: distinct abnormal EEG, aphasia; children appear deaf
- Selective mutism: Early development is not disturbed.
- Anxiety, ADHD, obsessive-compulsive disorder, reactive attachment

disorder or schizophrenia

TREATMENT

MEDICATION

- Pharmacotherapy treats associated symptoms of autism.
- Symptoms/medications to consider:
 - Self-injurious behavior: atypical/typical antipsychotics, guanfacine, clonidine
 - Sleep disturbances: melatonin, clonidine, trazodone
 - Seizures: newer anticonvulsants, carbamazepine, phenytoin, valproate, barbiturates (may worsen hyperactivity/irritability)
 - Hyperactivity/attention difficulties: psychostimulants, atomoxetine, bupropion, clonidine, guanfacine
 - Obsessive-compulsive disorder symptoms/perseveration: SSRIs, clomipramine
 - Tic disorders: guanfacine, clonidine, atypical/typical antipsychotics
 - Depression: SSRIs, bupropion, venlafaxine
 - Anxiety: SSRIs, buspirone, venlafaxine, benzodiazepines (may increase disorganization and agitation)
 - Aggression: atypical antipsychotics, SSRIs, anticonvulsants, guanfacine
- U.S. Food and Drug Administration (FDA)– approved medications include aripiprazole for ages 6–17 years and risperidone for ages 5–16 years
 - Important to monitor baseline glucose and lipids as atypical antipsychotics are associated with metabolic syndrome
 - Used for associated aggression and irritability

ALERT

- Autism spectrum disorders vary greatly in symptom presentation. Discordancy among clinicians' diagnoses and under- and overdiagnosis of these disorders are common.
- Symptom presentation differs at different stages of development.
- Medication often not helpful for core autistic features and patients

often develop side effects

- Subclinical seizure types may be detected only on electroencephalogram.

ADDITIONAL TREATMENT

General Measures

Nonpharmacologic

- Psychoeducational assessment
 - Cognitive ability and adaptive skills
 - Speech language assessment with both receptive and expressive language measures
 - Occupational therapy may be needed for sensory or motor difficulties
- Early sustained structured behavioral intervention using applied behavior analysis (ABA) and behavior modification highly beneficial in many children
- Vocational training important for some adolescents and adults
- Social skills training especially for higher functioning patients is essential.
- Education and support for parents and siblings integral to treatment
- Conventional psychotherapy not indicated to address core features of autism and pervasive developmental disorder

COMPLEMENTARY & ALTERNATIVE THERAPIES

- Almost 1/3 of children with ASD have received some form of complementary and alternative medicine (CAM).
- Important to ask and understand what is being used

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Prognosis linked to cognitive ability and acquisition of social/communication skills
- Early intervention and provision of services can improve prognosis.
- If no language by 5 years of age, substantial language development is

unlikely.

- Children with autism/pervasive developmental disorder often require lifelong treatment and support.
- Physician should remain active in long-term treatment planning and individual and family support.

DIET

Little systematic evidence to support that gluten-free diets are helpful, but there are many claims of their effectiveness

CODES

ICD10

- F84.0 Autistic disorder
- F84.2 Rett's syndrome
- F84.5 Asperger's syndrome

FAQ

- Q: What are the chances of having a 2nd child with autism?
- A: In families with 1 child with autism, the recurrence risk for subsequent children is 3–7%. This is in contrast to the risk in the general population, which is 0.1–0.2%.
- Q: What is the value of brain imaging in autism?
- A: MRI may help diagnose a heritable syndrome with genetic counseling implications (e.g., leukodystrophy, tuberous sclerosis) but is usually unhelpful in high-functioning cases without severe intellectual impairment and focal neurologic findings.
- Q: Does the MMR vaccine cause autism?
- A: There is no causal association between the MMR vaccine and autism.

AUTOIMMUNE HEMOLYTIC ANEMIA

Michele P. Lambert

BASICS

DESCRIPTION

- Autoimmune hemolytic anemia (AIHA) is characterized by shortened red cell survival that is caused by autoantibodies directed against RBCs, with or without the participation of complement on the red cell membrane.
- Natural history
 - Acute disease
 - Onset with rapid fall in hemoglobin level over hours to days
 - Usual course: complete resolution of disease within 3–6 months
 - Resolution more likely in children who present between 2 and 12 years of age
 - Chronic disease
 - Slower onset of anemia over weeks to months, with some having persistence of hemolysis or intermittent relapses
 - More likely to be associated with underlying chronic illness
 - More common in adults and children <2 years or >12 years of age

EPIDEMIOLOGY

- Less common in children and adolescents than in adults
- No apparent racial or sexual predisposition (in childhood)

Incidence

- ~1–3:100,000 persons/year
- Peak incidence in childhood is in first 4 years of life with warm AIHA.

PATHOPHYSIOLOGY

- Warm autoantibodies (~80% cases)
 - Maximal activity of in vitro antibody RBC binding at 37°C
 - IgG-class antibody usually
 - IgG-coated RBCs cleared, predominantly in the spleen, by

macrophages.

- Cold autoantibodies (cold agglutinins) (7–25%)
 - Maximal activity of in vitro RBC binding at temperatures between 0°C and 30°C
 - Almost always caused by IgM antibody with specificity for antigens of the i/I system on RBCs
 - Anti-I antibodies characteristic of *Mycoplasma pneumoniae*–associated hemolysis
 - Anti-I antibodies are usually found in infectious mononucleosis.
 - Hemolysis is complement-dependent.
- Paroxysmal cold hemoglobinuria
 - IgG autoantibody binds RBC at cooler areas of the body (i.e., extremities), causing irreversible binding of complement components (C3 and C4). When coated RBCs enter warmer areas of the body, IgG falls off and complement causes hemolysis (Donath–Landsteiner biphasic hemolysin).
 - Unusual IgG antibody with anti-P specificity
 - Most frequently found in children with viral infections (30%)

ETIOLOGY

- Idiopathic
- Passive transfer of maternal antibodies
- Secondary to an underlying disorder
 - Infection: viral (e.g., *Mycoplasma*, Epstein-Barr virus, cytomegalovirus, hepatitis, HIV) or bacterial (e.g., *Streptococcus*, typhoid fever, *Escherichia coli* septicemia)
 - Drugs: antimalarials, antipyretics, sulfonamides, penicillin, rifampin
 - Hematologic disorders: leukemia, lymphoma
 - Autoimmune disorders: lupus, mixed connective tissue disorders, Wiskott-Aldrich syndrome, ulcerative colitis, rheumatoid arthritis, common variable immunodeficiency, scleroderma, Evans syndrome, ALPS (autoimmune lymphoproliferative syndrome), 22q11.2 deletion syndrome
 - Tumors: ovarian, carcinomas, thymomas, dermoid cysts

DIAGNOSIS

HISTORY

- Pallor
- Jaundice
- Dark urine
- Fever
- Weakness
- Dizziness
- Syncope
- Exercise intolerance

PHYSICAL EXAM

- Pallor
- Jaundice
- Splenomegaly
- Hepatomegaly
- Tachycardia, systolic flow murmur, S₃ gallop
- Orthostasis in acute onset

DIAGNOSTIC TESTS & INTERPRETATION

Lab

CBC

- Hemoglobin level decreased (occasionally, thrombocytopenia seen in Evans syndrome).
- Mean corpuscular volume may be normal.
- Reticulocyte count increased (although may also be decreased if reticulocytes bear the target antigen).
- Peripheral smear: spherocytes, polychromasia, macrocytes, agglutination
- Direct antiglobulin test (Coombs)—positive (usually)
 - Single most important test
 - Warm AIHA will have IgG ± C3-positive.
 - Cold AIHA and paroxysmal cold hemoglobinuria will have C3-positive.
- Haptoglobin level decreased.

- Indirect hyperbilirubinemia
- Elevated lactate dehydrogenase
- Urinalysis: hemoglobinuria, increased urobilinogen
- Bone marrow aspiration: erythroid hyperplasia (to rule out leukemia or lymphoma associated with AIHA)
- Cold agglutinin titer: positive (usually >1:64)
- Donath–Landsteiner test should be performed in cases of suspected paroxysmal cold hemoglobinuria.

ALERT

- A negative Coombs test can occur when small numbers of IgG or C3 molecules are present on the red cell membrane or if most of the coated red cells are cleared from circulation (i.e., in cases of less severe hemolysis, low-affinity antibodies, or in cases of very severe, rapid clearance).
- Radiolabeled Coombs test or enzyme immunoassays are more sensitive diagnostic tests in these circumstances.
- Reticulocytopenia may occur in some cases where the antibody coats and removes reticulocytes.

DIFFERENTIAL DIAGNOSIS

- Defects intrinsic to RBC:
 - Membrane defects such as hereditary spherocytosis
 - Enzyme defects including hemolytic episode due to G6PD deficiency
 - Hemoglobin defects
 - Congenital dyserythropoietic anemias
 - Paroxysmal nocturnal hemoglobinuria
- Defects extrinsic to RBC:
 - Immune-mediated
 - Isoimmune: hemolytic disease of the newborn, blood group incompatibility
 - Autoimmune (see “[Etiology](#)”)
 - Drug-dependent RBC antibodies
 - Hemolytic transfusion reaction
 - Non-immune-mediated

- Idiopathic
- Secondary to an underlying disorder (i.e., hemolytic uremic syndrome, thrombotic thrombocytopenic purpura)
- Mechanical: march hemoglobinuria, heart valves

TREATMENT

MEDICATION

First Line

Corticosteroids

- Indication:
 - In IgG-mediated disease, steroids have been shown to interfere with macrophage Fc and C3b receptors responsible for RBC destruction. In addition, they have been shown to elute IgG Ab from the RBC surface (improving survival).
 - In chronic, warm, AIHA, pulsed high-dose dexamethasone has been shown to be effective in some cases.
- Complications:
 - Both short- and long-term side effects
 - Generally not effective in cold agglutinin disease
- Dose:
 - Start prednisone PO/methylprednisolone IV at 2 mg/kg/24 h in divided doses.
 - Tapering of steroids should begin after a therapeutic response is achieved (may take several days to weeks).
- Goal:
 - Initially, to return to normal hemoglobin level with tolerable doses of steroid or off steroids entirely
 - In some patients, goal may be achieving decreased hemolysis and a clinically asymptomatic state with minimal steroid side effects.
 - Alternative treatments should be considered for patients unresponsive to steroids or who require high doses for maintenance of hemoglobin level.

Second Line

- IV immunoglobulin
 - Indication:
 - May be useful in selected cases of immune hemolytic anemia unresponsive to steroids
 - Mechanism of action is not entirely clear.
 - Effect is usually temporary; retreatment may be required every 3–4 weeks.
 - Complications:
 - Red cell antibodies in IVIG preparations may be a confounder.
 - Aseptic meningitis
 - Theoretical risk of transfusion-transmitted viral infection
 - Expensive
 - Dose: Up to 1 g/kg/24 h for 5 days has been required to achieve a beneficial effect.
 - Large doses of IVIG have been associated with causing hemolytic anemia.
- Plasmapheresis/exchange transfusion
 - Indication:
 - Will slow the rate of hemolysis in severe disease, especially if IgM-mediated
 - Indicated if thrombotic thrombocytopenic purpura cannot be excluded
 - Complications:
 - Only of short-term benefit
 - Expensive
- Rituximab: monoclonal anti-CD20 antibody likely works through depletion of B cells
 - Indicated in refractory AIHA (375 mg/m² weekly for 2–4 weeks)
 - Response 40–100%
 - Particularly useful in warm AIHA
 - Adverse effects: fever, chills, rigors, hypertension, bronchospasm; rare risk of viral infections
- Immunosuppressive agents (antimetabolites and alkylating agents)
 - Indication:
 - When there is a clinically unacceptable degree of hemolysis that

- is refractory to steroids and splenectomy
- Some have been effective in cold agglutinin disease.
 - Complications:
 - There are varying side effects dependent on the agent used. Therefore, clinical indications must be strong and exposure to drug should be limited.
 - Dose:
 - Adjusted to maintain WBC >2,000, absolute neutrophil count (ANC) >1,000, and platelet count at 50,000–100,000 cells/mm³
- Alemtuzumab (anti-CD52): may be effective very refractory AIHA particularly secondary to B-cell chronic lymphocytic leukemia (B-CLL)

ADDITIONAL TREATMENT

General Measures

Blood transfusion: should only be used with great caution in this setting in patients with very low hemoglobin/brisk hemolysis because of difficulty with appropriate cross-matching

- Indication: physiologic compromise from the anemia (usually only in severe acute onset)
- Complications:
 - The blood bank may be unable to find compatible blood. In IgG-mediated disease, autoantibody is usually pan-reactive; therefore, you must use the least incompatible unit of blood.
 - In cold agglutinin disease, use a blood warmer for all infusions to decrease IgM binding, and monitor for acute hemolysis during transfusion.

SURGERY/OTHER PROCEDURES

Splenectomy

- Indication:
 - Patients unresponsive to medical management, who require moderate- to high-maintenance doses of steroids or who develop steroid intolerance may be candidates.
- Not effective in cold agglutinin disease
- Response rate is 50–70%, with many partial remissions.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Hemoglobin level q4h–q12h (depending on severity) until stable
- Reticulocyte count: daily
- Spleen size: daily
- Hemoglobinuria: daily
- Coombs: weekly

PROGNOSIS

- Dependent on age, underlying disorder (if any), and response to therapy. See also “[Description](#)” section (natural history).
- Mortality in pediatric series ranged from 9 to 19%.

COMPLICATIONS

- May be increased risk of venous thrombosis in patients with AIHA
- May be associated with a predisposition to lymphoproliferative disorders
- Gallstones related to chronic hemolysis

CODES

ICD10

- D59.1 Other autoimmune hemolytic anemias
- D59.0 Drug-induced autoimmune hemolytic anemia

FAQ

- Q: Will the anemia go away?
- A: Children with cold autoantibodies tend to have short-lived illness, whereas children with warm antibodies often have a chronic clinical course characterized by periods of remissions and relapses.
- Q: Is this contagious?
- A: No. Another child may acquire the same viral illness; however, the body's response to produce an autoantibody is dependent on the individual patient.

AVASCULAR (ASEPTIC) NECROSIS OF THE FEMORAL HEAD (HIP)

Craig Munns

BASICS

DESCRIPTION

- Avascular (aseptic) necrosis results from the interruption of the blood supply to bone (either traumatic or nontraumatic occlusion).
- The femoral head is the most common site.
- A particular type of self-limiting idiopathic avascular necrosis of the hip that occurs in children is known as Perthes disease (see the “[Perthes Disease](#)” chapter).

RISK FACTORS

Genetics

Variable, depending on cause

PATHOPHYSIOLOGY

- Death and necrosis of bone with gradual return of blood supply
- Necrotic bone gradually resorbed and replaced by new bone
- During bone resorption, structural integrity of femoral head may be reduced, leading to collapse.

ETIOLOGY

- Traumatic
 - Hip fracture
 - Hip dislocation
 - Slipped capital femoral epiphysis
 - Complication of casting, bracing, surgery
- Nontraumatic
 - Idiopathic (older, after physeal closure); similar to adult avascular necrosis
 - Idiopathic (younger, before physeal closure, Perthes disease)
 - Caisson disease

- Sickle cell disease
- Septic arthritis
- Steroids or chemotherapy
- Malignancy (leukemia)
- Gaucher disease
- Viral infection (HIV, CMV)
- Radiation therapy
- Hypercoagulable states

DIAGNOSIS

HISTORY

- Onset (gradual or after traumatic event)
- Association with the following:
 - Trauma
 - Medications (steroids or chemotherapy)
 - Casting, splinting, surgery (iatrogenic)
 - Pain, limping
 - Stiffness (decreased range of motion)
 - Perthes disease may occasionally be bilateral or occur in contralateral hip at a later time point.

PHYSICAL EXAM

- Gait
 - Limping
 - Antalgic (“against pain”) gait (shortened stance phase relative to swing phase)
 - Trendelenburg gait
- Note range of motion:
 - Flexion and extension
 - Abduction and adduction
 - Internal and external rotation
- Hip joint irritability (short arc rotation)
- Signs of other disease processes associated with avascular necrosis (e.g., sickle cell disease)

- Physical examination pearl
 - Loss of internal rotation is usually the first and most affected loss of motion seen.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Laboratory examinations should be normal in most forms of avascular necrosis of the femoral head.
- Exceptions:
 - Sick cell disease
 - Septic arthritis
 - Chemotherapy

Imaging

- Radiographic findings:
 - Sclerosis
 - Subchondral fracture
 - Collapse
 - Reossification
 - Repair
- Magnetic resonance imaging (MRI)
 - Bone edema
 - If contrast medium used, area of reduce blood flow evident
- Bone scan
 - Reduced signal in affected hip
- Other potential findings:
 - Cysts
 - Physeal growth arrest (young)
 - Early osteoarthritis
 - Subluxation

DIFFERENTIAL DIAGNOSIS

- Trauma
 - Osteochondral fracture
 - Impaction fracture
 - Epiphyseal/physeal fracture
- Infection

- Osteomyelitis
- Septic arthritis
- Neoplastic process: epiphyseal tumors (chondroblastoma, Trevor disease, etc.)
- Rheumatologic processes
- Skeletal dysplasia, particular if bilateral hip involvement

TREATMENT

MEDICATION

- NSAIDs may reduce pain by decreasing associated inflammation but may also reduce new bone formation.
- If associated with corticosteroid use, discontinuation or elimination of steroids may be helpful if appropriate.
- Bisphosphonate therapy may help preserve joint shape.

ADDITIONAL TREATMENT

General Measures

- Maintain range of motion (physical therapy, traction, continuous passive motion).
- Contain the femoral head in the acetabulum (see treatment principles listed in “[Perthes Disease](#)” chapter).
- Duration of therapy variable, depending on cause
- Reduced weight bearing on affected hip may help prevent collapse.

SURGERY/OTHER PROCEDURES

Redirectional osteotomy

- Femoral or acetabular reorientation
- Core decompression to stimulate new blood supply

ONGOING CARE

DIET

- Thought not to alter disease process
- Recommend general balanced diet

- During immobilization, excessive weight gain may occur.

PROGNOSIS

- Depends on extent of femoral head collapse
- Good if mild involvement and patient is young
- When to expect improvement: variable, depending on cause
- Moderate to severe cases often have significant collapse and end up requiring a total hip replacement.

COMPLICATIONS

- Joint collapse with decreased range of motion, pain, limping
- Osteoarthritis
- Physeal arrest with growth disturbance

ALERT

Signs to watch for:

- Subluxation
- Early osteoarthritis
- Growth arrest

femoral epiphysis. J Bone Joint Surg Am. 2003;85-A(5):798–801.

CODES

ICD10

- M87.059 Idiopathic aseptic necrosis of unspecified femur
- M91.10 Juvenile osteochondrosis of head of femur, unspecified leg
- M87.052 Idiopathic aseptic necrosis of left femur

FAQ

- Q: What type of medication is most often associated with avascular necrosis of the hip?
- A: Corticosteroids
- Q: For avascular necrosis in children (Perthes disease of the hip, for example), is younger or older age associated with a better prognosis?
- A: Younger age (<8 years)

BABESIOSIS

Oluwakemi B. Badaki-Makun • Frances M. Nadel

BASICS

DESCRIPTION

- Human babesiosis is a tick-borne malaria-like illness characterized by fever, malaise, and hemolytic anemia.
- Most infected individuals are asymptomatic.

EPIDEMIOLOGY

- Human babesiosis is a protozoal illness caused by the intraerythrocytic parasite of the *Babesia* genus.
 - *Babesia microti* is responsible for most cases of babesiosis in the United States.
 - *Babesia divergens* is responsible for most European cases.
- The parasite is transmitted by the tick vector *Ixodes scapularis* (deer tick), the same vector responsible for transmission of *Borrelia burgdorferi* (the causative agent in Lyme disease)
- The white-footed mouse (*Peromyscus leucopus*) is the primary reservoir host of *Babesia*.
- Most cases in the United States occur in the Northeast and Upper Midwest.
 - 96% of reported cases in 2012 occurred in Connecticut, Massachusetts, New Jersey, New York, Rhode Island, Minnesota, and Wisconsin.
- Human infection most commonly occurs in the warm months—late spring to early fall.

Incidence

- In January 2011, babesiosis became a nationally notifiable disease monitored by the Centers for Disease Control and Prevention (CDC).
- According to the CDC, 937 cases were reported in the United States in the year 2012, more cases than meningococcal disease, streptococcal toxic shock syndrome, or botulism combined.

Prevalence

- Prevalence is difficult to ascertain as asymptomatic infection appears to be common in endemic areas. For instance, seroprevalence is as high as 9% in some endemic areas of Rhode Island.

RISK FACTORS

- Asplenia (functional or anatomic)
- Extremes of age, especially age >50 years
- HIV/AIDS
- Immunosuppressive medications
- Malignancy
- Primary immunodeficiency syndrome

Genetics

There is no known genetic predisposition.

GENERAL PREVENTION

- Prevention begins with avoidance of tick bites.
- Simple measures include wearing long-sleeved shirts and long pants, with pants tucked into the socks in tick-infested areas.
- Avoid endemic regions during the peak months of May to September.
- Light clothing will make ticks easier to see.
- Use DEET-containing insect repellents during outdoor activities.
- Spraying one's clothing with a permethrin tick repellent may be helpful.
- Children and dogs should be inspected daily for ticks after being outside.
- Prophylaxis is not recommended after a tick bite.
- No vaccine is currently available.
- There is currently no universal laboratory screening of blood products.

PATHOPHYSIOLOGY

- Babesial infection of the erythrocyte causes membrane damage and lysis, which promotes adherence to the endothelium and microvascular stasis.
- This process results in a hemolytic anemia.
- The spleen plays an important role in decreasing the protozoal load

through antibody production and filtering of abnormally shaped infected red blood cells.

ETIOLOGY

- A bite from an infected tick transmits the protozoa.
- Incubation period
 - Usually 1–4 weeks for tick-transmitted disease
 - 1–9 weeks for transfusion-associated disease
- Human-to-human transmission is limited to infection through contaminated blood.
 - Babesiosis is currently the most common transfusion-transmitted infection in the United States.
 - Rare cases of transplacental and perinatal infection have been reported.

COMMONLY ASSOCIATED CONDITIONS

- 11–23% of patients have concurrent Lyme disease.
 - Coinfections with *Borrelia* account for 80% of tick-borne coinfections.

DIAGNOSIS

HISTORY

- Few patients recall a tick bite.
- Patients live in or have recently traveled to an endemic region.
- Initial symptoms begin 1–4 weeks after the tick bite and are vague. They may include progressive fatigue, malaise, headaches, and anorexia, accompanied by intermittent fevers as high as 40°C.
- Chills, myalgias, and arthralgias may follow these symptoms.
- Less common complaints include cough, sore throat, abdominal pain, and emotional lability.

PHYSICAL EXAM

- Fever and tachycardia are often the only findings.
- Mild conjunctival injection and pharyngeal erythema occasionally occur.

- Mild hepatomegaly and/or splenomegaly may be seen.
- Jaundice or hematuria may also be observed.
- Petechiae and ecchymosis occur in rare cases, most often in the presence of severe illness with associated shock and/or DIC.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Giemsa- or Wright-stained thick and thin blood smears may demonstrate the intraerythrocytic ring form:
 - This is often confused with the ring form of *Plasmodium falciparum*, the etiologic agent of malaria.
 - Rarely, the pathognomonic “Maltese cross” forms of the *Babesia* parasite may be seen on the blood smear.
 - Multiple smears should be performed as initial smears may be falsely negative.
- Indirect immunofluorescent assay
 - Antigen-specific for *B. microti*
 - In endemic areas, the test has a sensitivity of 91% and a specificity of 99%.
 - Can be used when blood smears are negative
 - In general, a titer = 1:64 indicates exposure.
 - Titer = 1:256 suggests acute infection.
 - There is little correlation between titer levels and severity of disease.
 - Immunoglobulin levels decline rapidly within months of recovery.
- Polymerase chain reaction is highly sensitive and specific when available.
- Other tests: Most of the abnormal routine test results are the result of hemolysis.
- Urinalysis
 - Proteinuria
 - Hemoglobinuria
- CBC
 - Normal leukocyte count/leukopenia
 - Normocytic/normochromic anemia
 - Thrombocytopenia

- Atypical lymphocytosis
- Reticulocytosis
- Possible positive Coombs test
- Elevated ESR
- Liver function tests: elevated bilirubin, lactate dehydrogenase, and liver transaminases
- Elevated BUN and creatinine
- In asymptomatic patients, these tests are often normal.

ALERT

False negatives:

- Blood smears may not demonstrate the protozoa at low levels of parasitemia.
- Serologic false positives for *B. microti* include cross-reactivity with other *Babesia* sp. or malarial organisms

DIFFERENTIAL DIAGNOSIS

- Ehrlichiosis
- Influenza
- Lyme disease
- Malaria
- Nonspecific viral syndrome

TREATMENT

MEDICATION

- No treatment is required for asymptomatic patients who are otherwise healthy.
- For symptomatic patients, treatment is generally for 7–10 days regardless of regimen; more severely ill patients may require a longer duration of therapy.

First Line

- Clindamycin in combination with quinine
 - Standard therapy for asplenic, immunodeficient, or severely ill patients

- Pediatric dosing:
 - Clindamycin: 20–40 mg/kg/day IV/PO divided q6–8h (max 600 mg/dose)
 - Quinine: 30 mg/kg/day PO divided into 3 doses
- Adult dosing:
 - Clindamycin: 600 mg PO q8h or 300–600 mg IV q6h
 - Quinine: 650 mg PO q8h

Second Line

- Atovaquone in combination with azithromycin
 - Has similar treatment effectiveness with fewer side effects (such as vertigo, tinnitus, and GI upset) than clindamycin and quinine in adults
 - Use of atovaquone and azithromycin has not been studied in the pediatric population; clindamycin and quinine are the recommended treatment choice for symptomatic children.
- Pediatric dosing:
 - Atovaquone 40 mg/kg/day PO divided into 2 doses (max 750 mg q12h)
 - Azithromycin 10 mg/kg/day (max 500 mg) PO on day 1 and 5 mg/kg/day (max 250 mg) PO daily thereafter
- Adult dosing:
 - Atovaquone 750 mg PO q12h
 - Azithromycin 500–1,000 mg PO on day 1 and 250–1,000 mg PO daily thereafter
- In areas endemic for Lyme disease and ehrlichiosis, consider adding doxycycline to either regimen until lab confirmation of absence of either disease in the patient with babesiosis.

ADDITIONAL TREATMENT

General Measures

Those with mild clinical disease usually recover without treatment.

ADDITIONAL THERAPIES

- For life-threatening infections, exchange transfusion has been successful. Consider in patients with severe parasitemia ($\geq 10\%$), severe hemolysis, or renal/hepatic/pulmonary compromise.

- Progressive respiratory distress may require mechanical ventilation.

ALERT

- Signs to watch for:
 - Respiratory distress, especially after treatment has begun
 - Pancytopenia and lymphadenopathy: may indicate the development of hemophagocytic syndrome
- Pitfalls
 - Children who are from endemic areas and have an acute febrile illness may be misdiagnosed with a nonspecific viral illness.
 - One should be suspicious for a coinfection with Lyme disease or ehrlichiosis in those who are not responding to standard therapy.
 - Delayed recognition of this uncommon disease may be life threatening in the immunocompromised patient.
 - In endemic areas, babesiosis should be considered in a posttransfusion febrile illness in at-risk populations.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

When to expect improvement:

- Some improvement of symptoms should be noted within 24–48 hours of onset of therapy.
- Those who are only mildly affected usually have resolution of their symptoms over a few weeks.
- For severely affected and immunodeficient patients, the convalescent period may be as long as 18 months.
- In untreated asymptomatic individuals, parasitemia may persist for months to years.
- Long-term complications are rare.
- Recrudescence has been reported.

COMPLICATIONS

- Rarely fatal in the United States
- Pancytopenia and overwhelming secondary bacterial sepsis may occur.
- Serious and fulminant complications have been described:

- Pulmonary edema and adult respiratory distress syndrome, often happening after treatment has begun.
- CHF
- Renal failure
- Hemophagocytic syndrome/DIC
- Seizures/coma
- Those coinfecting with Lyme disease are susceptible to more severe disease and complications.

CODES

ICD10

B60.0 Babesiosis

FAQ

- Q: How long does a tick have to be attached for infection to occur?

- A: In general, successful transmission requires at least 24 hours of attachment.
- Q: How should a tick be removed?
- A: The tick should be grasped with forceps as close to its head as possible and pulled straight up. If possible, it should be saved for identification.
- Q: Does infection confer lifetime immunity?
- A: Reinfection is possible.

BACK PAIN

Danielle N. Clark • Peter Chira

BASICS

DESCRIPTION

Any condition causing pain of the thoracic, lumbar, or sacral spine

EPIDEMIOLOGY

- 12-month period prevalence: 10–20% of children
- Lifetime prevalence: 12–50%

RISK FACTORS

- Poor conditioning or high athletic performance
- Joint hypermobility
- Role of backpack weight and style of wear undetermined
- Role of overweight or obesity yet to be determined

GENERAL PREVENTION

- Back muscle strengthening and hamstring stretching exercises may be helpful.
- Maximum backpack load: 10–15% body weight
- Weight loss and increased physical activity in overweight or obese children

PATHOPHYSIOLOGY

- Dependent on underlying cause
- Hyperextension with rotational spinal loading in the case of pars defects (e.g., spondylolysis or spondylolisthesis)
- Autoimmune or autoinflammatory processes as with juvenile idiopathic arthritis (JIA) or juvenile ankylosing spondylitis

ETIOLOGY

- Unidentified in 50% of cases
- 30% of chronic cases (back pain >3 years) without clear etiology despite workup

DIAGNOSIS

HISTORY

- History can be helpful with elucidating most likely cause.
- Musculoskeletal/trauma
 - Direct trauma
 - Worsening pain after activity
 - Repetitive movements causing microtrauma
- Inflammatory
 - Morning stiffness (variable pain)
 - Pain/stiffness improves with movement.
 - Family history of rheumatic disease
- Infectious
 - Fever
 - Recent exposure to infection or tuberculosis (TB)
- Malignancy
 - Night sweats, fever, weight loss, malaise, pain waking at night
 - Previous history of malignancy
- Neurologic
 - Radiating pain or foot drop
 - Loss of bowel or bladder function
- Endocrine/metabolic
 - Long-term steroid use
 - Vitamin D deficiency
- Psychosocial stressors (e.g., family coping mechanisms and response to pain and stress)

PHYSICAL EXAM

- **Finding:** observation: sacral dimple, vascular anomalies, posture, spinal curvature, anterior superior iliac spine (ASIS) height, limb length discrepancy, foot arch, lower limb alignment, rib rotation
 - Significance: occult problem; mechanical or musculoskeletal problem. Scoliosis is rarely painful. Increased fixed kyphosis of 40 degrees is indicative of Scheuermann disease.
- **Finding:** palpation: point or focal tenderness along spine; sacroiliac

(SI) joint tenderness

- Significance: If bony, consider fracture, vertebral osteomyelitis; if paraspinal, consider muscle strain. If SI tenderness, consider spondylitis.
- **Finding:** range of motion: pain with spinal extension (causing strain of anterior elements of spine)
 - Significance: Consider spondylolisthesis (forward vertebral displacement), spondylolysis (vertebral defect), fracture, vertebral osteomyelitis, or tumor.
- **Finding:** range of motion: forward spinal flexion limitation
 - Significance: If painful, consider diskitis, vertebral osteomyelitis, vertebral body tumor, and herniated disc if pain radiates.
 - Significance: If limited as noted by flattening of lumbosacral region with movement, consider spondylitis.
- **Finding:** range of motion: restriction of spine with pain (especially with neck extension) and other associated joint abnormalities (swelling or pain/tenderness with limitation)
 - Significance: Consider JIA.
- **Special Tests:** pain with straight-leg raise: Consider tight hamstrings, psoas strain, or disc herniation.
- **Special Tests:** pain with FABER (flexion, abduction, external rotation with foot on opposite knee) testing or direct palpation of SI joint: SI joint irritation or inflammation
- **Special Tests:** Assess reflexes, sensation, Babinski, pain, and proprioception; deficits may indicate neuronal involvement.
- Abdominal or pelvic exam may be helpful.

DIAGNOSTIC TESTS & INTERPRETATION

- **Tests:** CBC with differential, sedimentation rate, C-reactive protein (CRP), and comprehensive metabolic panel with uric acid and LDH
 - Significance: malignancy, infection, inflammatory
- Antinuclear antibody, rheumatoid factor, anticyclic citrullinated antibody, and HLA B27 only if obvious other associated joint abnormalities found
 - Significance: inflammatory/autoimmune disorders
- Cultures, PPD, or other TB study

- Significance: infection
- 25-OH vitamin D, PTH, calcium, phosphorus, alkaline phosphorus
 - Significance: vitamin D deficiency or osteoporosis

Imaging

- Plain x-rays
 - AP and lateral; oblique and flexion/extension (if warranted) of the spine
 - Assess for fracture, spinal curvature, osteomyelitis, and masses.
 - Intra-articular pars defect commonly in L4/L5 indicates spondylolysis.
 - Bilateral pars defect with vertebral body displacement indicates spondylolisthesis.
- Bone scan
 - Occult/subtle bony lesions and spondylolysis and spondylolisthesis
- CT spine
 - Useful to categorize lesions seen on bone scan such as spondylosis/spondylolisthesis
- MRI
 - Tumor, infection, disk injuries, synovitis (including effusions or erosions), and neurologic findings

DIFFERENTIAL DIAGNOSIS

- Mechanical/trauma
 - Overuse injury
 - Disc herniation
- Direct trauma, contusion
 - Musculoskeletal strain in children with closed growth plates
 - Apophyseal ring fracture
- Structural
 - Pars defects: children usually >10 years of age
 - Spondylolysis/spondylolisthesis (anterior displacement/“slip” of vertebral body, evolution of bilateral spondylolysis)
 - Scheuermann kyphosis: deformity of thoracic spine associated with vertebral body wedging
- Inflammatory

- JIA
- Juvenile ankylosing spondylitis
- Chronic recurrent multifocal osteomyelitis
- Neoplastic
 - Ewing sarcoma
 - Lymphoma, leukemia
- Infectious
 - Osteomyelitis
 - Epidural abscess
 - Pyelonephritis
 - Diskitis
- Endocrine/metabolic
 - Osteoporosis
 - Vitamin D deficiency
- Other
 - Pain amplification syndrome (fibromyalgia, myofascial pain)
 - Sick cell crises, abdominal disease (pancreatitis, pyelonephritis)
- Age differentiation
 - <10 years: diskitis, tumor, epidural
 - >10 years: pars defects, inflammatory disorders

ALERT

- Warning signs of potentially serious causes of back pain in children include the following:
 - Young age: <7 years old
 - Duration of pain: >4 weeks
 - Acute trauma
 - Night pain, fever, weight loss, or malaise
 - Abdominal mass
 - Early morning stiffness
 - History of tumor
 - Exposure to TB
 - Limp
 - Chronic interference with normal activity (e.g., school, sports, play)
 - Postural changes causing scoliosis or kyphosis
 - Other associated joint abnormalities (swelling OR pain/tenderness)

with joint limitation)

TREATMENT

MEDICATION

- Nonsteroidal anti-inflammatory drugs (NSAIDs) for overuse or strains in adolescents and for patients with arthritis
- Additional medication may be necessary depending on underlying condition such as antibiotics for infection, chemotherapy for malignancy, immunosuppression for inflammatory/autoimmune, or vitamin D and calcium supplementation for vitamin D deficiency or osteoporosis.

ADDITIONAL TREATMENT

General Measures

- If no warning signs, conservative management with NSAIDs, physical therapy, and close follow-up are appropriate.
- Abnormal exam/history or focal symptoms warrant imaging.
- Spondylolysis/spondylolisthesis
 - <50% slip: conservative medical treatment
 - >50% slip/persistent back pain: surgical treatment
- Diskitis: antistaphylococcal coverage
- Bed rest/activity limitation: Adult data do not support this strategy.

ISSUES FOR REFERRAL

- Sports medicine or orthopedics appropriate with Scheuermann disease, spondylolysis or spondylolisthesis
- Concern for malignancy or long-standing inflammatory process such as JIA or juvenile ankylosing spondylitis warrants referral to hematology/oncology or rheumatology, respectively.
- Endocrinology referral for suspected osteoporosis

ADDITIONAL THERAPIES

- Physical therapy with focus on core strength and flexibility if cause is due to overuse or due to a sedentary lifestyle
- Removal from activity for overuse injuries with slow gradual return

- Structural problems such as spondylolysis, spondylolisthesis, and Scheuermann disease often respond to rest, ice, NSAIDs, and thoracolumbar-sacral orthosis bracing.
- A biopsychosocial approach is needed for patients with pain amplification syndromes in conjunction with physical and cognitive behavioral therapies and emphasis on functionality.

COMPLEMENTARY & ALTERNATIVE THERAPIES

- Yoga and Pilates emphasizing core strength and flexibility may be useful in the adolescent.
- Cochrane systematic review determined massage may be useful in the setting of acute or subacute back pain in adults.
- Acupuncture may be useful for dealing with pain.

SURGERY/OTHER PROCEDURES

Indicated in patients with spondylolisthesis slip of >50%

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Patients managed conservatively should be reevaluated within 2 weeks and then spaced further as their pain improves.
- If symptoms not improving with conservative measures, then consider workup as outlined and appropriate referral depending on results.

Patient Monitoring

No specific lab tests need to be routinely followed.

PATIENT EDUCATION

- Patients and families need to be aware that musculoskeletal and structural causes may take several weeks to heal.
- Pain in spondylolysis and spondylolisthesis does not always correlate with degree of involvement.
- Patients should be told to report changes in symptoms, especially any red flags.

PROGNOSIS

- Dependent on the underlying cause
- With proper diagnosis and treatment, the majority do well, without significant sequelae.
- Not possible to predict future course of spondylolysis, spondylolisthesis, or Scheuermann kyphosis

COMPLICATIONS

- Contractures and loss of function
- Paralysis, other permanent neuromuscular injury
- Chronic back pain or development of pain amplification syndrome

ADDITIONAL READING

CODES

ICD10

- M54.9 Dorsalgia, unspecified
- M54.6 Pain in thoracic spine
- M54.5 Low back pain

FAQ

- Q: Which children with back pain should have activity restriction?
- A: Children with spinal or bony abnormalities should avoid hyperextension and high-impact sports.
- Q: When can/should the child resume activities after an acute back

injury?

- A: Children with a normal neurologic exam and diagnostic studies can resume activity or sports as tolerated.
- Q: Should a trial of steroids be used to rule out inflammatory back pain?
- A: Pain improvement with glucocorticoids may suggest an inflammatory condition but is not diagnostic. It is not recommended in children, as it can often complicate the clinical picture, as noninflammatory back pain will sometimes respond to treatment as well.

BAROTITIS

Judith Brylinski Larkin

BASICS

DESCRIPTION

- Barotrauma of the middle or inner ear, most commonly caused by flying in an airplane or scuba diving but also caused by elevators and high altitudes
- May also be seen in those who have used a hyperbaric oxygen chamber and in people involved in explosions—blast injuries
- Referred to as “middle ear squeeze” by scuba divers

EPIDEMIOLOGY

- Severe disease is uncommon in commercial aircraft because of pressurization.
- Significant disease is more common in scuba divers, in those who fly military aircraft, and during use of hyperbaric oxygen chambers.
- There is wide variation, with studies reporting an incidence of 8–55% for children after a single flight.
- Most studies agree that the incidence is ~20% in adults after a single flight.
- 40% frequency in scuba diving

RISK FACTORS

- Age: Infants or toddlers are at higher risk because of small eustachian tubes.
- Disease states that impede normal eustachian tube function: otitis media, upper respiratory tract infection (URI), allergic rhinitis
- Smoking
- Vigorous use of Valsalva maneuver

GENERAL PREVENTION

- Gradual descent during scuba diving—never rapid
- When ascending, divers should avoid rising more quickly than their air

bubbles.

- Yawning, swallowing, chewing, or doing Valsalva maneuver during takeoff and landing in planes and during ascent and descent when scuba diving
- Gentle Valsalva—never vigorous
- Avoid flying or diving when you have a URI or allergic rhinitis.
- Avoid sleeping on plane during takeoff and landing.
- Break seal of wet suit hood to allow water to fill external canal before descent.
- Avoid use of earplugs.

PATHOPHYSIOLOGY

- Boyle's law states that as pressure of a gas decreases, volume increases, and as pressure of a gas increases, volume decreases.
- Ambient pressure decreases during airplane/scuba diving ascent and increases during descent.
- During ascent, the tympanic membrane (TM) bulges outward and the eustachian tube vents the excess middle ear pressure. Pressure is easily equalized.
- During descent, the TM bulges inward and the eustachian tube resists inward flow of air. Pressure equalization is difficult.
- At a pressure differential of 60 mm Hg (greater ambient to middle ear pressure), subjective discomfort is reported.
- At a pressure differential of 90 mm Hg, the eustachian tube collapses and becomes obstructed. Autoinflation is unsuccessful.
- TM can rupture at pressure differentials >100–400 mm Hg.
- Barotitis is sometimes classified using Teed classification of disease severity (see “[Physical Exam](#)”).

ETIOLOGY

Differences in the atmospheric pressure between the inner ear, middle ear, and environment result in injury to the middle and/or inner ear.

DIAGNOSIS

HISTORY

- Ear pain, pressure sensation, diminished hearing
- Symptoms of inner ear damage may include vestibular and/or auditory complaints including tinnitus, vertigo, nausea, and vomiting.
- History of recent airplane flying, scuba diving, or hyperbaric oxygen chamber use

PHYSICAL EXAM

- Nystagmus
- Hearing loss
- Teed classification to describe appearance of the TM:
 - Grade 0: symptoms without physical signs
 - Grade 1: diffuse redness and retraction of TM
 - Grade 2: grade 1 plus slight hemorrhage into TM
 - Grade 3: grade 1 plus gross hemorrhage into TM
 - Grade 4: bulging TM with air–fluid level, blood in TM
 - Grade 5: free hemorrhage into TM and ear canal with perforation of TM

DIAGNOSTIC TESTS & INTERPRETATION

Imaging

CT of the inner ear may be indicated in patients with vestibular symptoms or hearing loss to rule out inner ear damage.

Diagnostic Procedures/Other

Hearing tests should be performed on all patients who have signs of barotrauma and on patients with normal physical exams but who are symptomatic.

DIFFERENTIAL DIAGNOSIS

- Otitis media with effusion
- Acute otitis media
- Otitis externa
- Blunt trauma to the TM
- Exposure to extremely loud noise

TREATMENT

MEDICATION

- Nasal decongestant sprays (oxymetazoline [Afrin])
 - Have been reported by some to be helpful, but a randomized clinical trial showed no advantage over placebo
 - Theory: By constricting mucosal arterioles, eustachian tube function is enhanced.
 - Topical decongestants are used 1 hour prior to plane travel/diving and 1/2 hour prior to plane descent.
 - 2 drops/sprays per nostril
 - Use in children older than 6 years of age.
- Oral decongestants
 - 2 randomized controlled trials suggest that oral decongestants may be effective, although a trial in children did not show a beneficial effect.
 - May be helpful through the same physiologic pathway as topical agents
 - Should be initiated 1–2 days prior to the expected pressure change
- Antihistamines
 - May also be helpful by reducing mucosal edema and enhancing the eustachian tube orifice
 - Can be used on the day of the expected pressure change
- Nasal surfactants may be useful but ongoing studies are needed.
- Pain relievers such as acetaminophen, ibuprofen, and naproxen may be useful for severe pain.

ADDITIONAL TREATMENT

General Measures

- Valsalva maneuver (blowing the nose while pinching the nostrils closed) may be helpful when diving or descending and will force air into the middle ear via the eustachian tube, thereby equalizing the pressure between the middle ear and the environment. This should be done gently.
- Swallowing, yawning, and chewing can help to release pressure through the eustachian tube when descending in an airplane or when returning to the water surface while scuba diving.
- Politzer bag: instrument used for clearing pressure disequilibrium that

- has not improved with Valsalva maneuvers and a trial of decongestants
- Otovent: Another instrument that may be used for treatment or prevention; usage can be taught to children as young as 2–6 years of age.
 - Myringotomy with or without tubes may be required to relieve pressure in severe disease. It may also be used as a preventive measure in those with a history of barotitis.
 - Myringotomy is effective for the patient with excruciating pain or unrelenting eustachian tube dysfunction; this is best performed by an otolaryngologist.

SURGERY/OTHER PROCEDURES

Rarely, myringotomy with or without tube insertion is required to relieve pressure and pain as well as prevent complications. Myringotomy is a surgical procedure where a small incision is made in the TM. This opens the middle ear space and equalizes the pressure on both sides of the TM. Myringotomy without tube insertion will relieve pressure, but the opening may close very quickly and may not allow time for the barotrauma to heal; on occasion, myringotomy with tube insertion is necessary. Tympanostomy tubes are not appropriate for scuba divers.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

Most patients with barotitis can be managed conservatively. Those with complications noted earlier require specialist referral.

PROGNOSIS

- Complete spontaneous resolution in mild cases
- Middle ear barotrauma is usually self-limited and correctable with the techniques described in the “General Measures” section. In rare instances, where there is severe pain or eustachian tube dysfunction, myringotomy with or without tube insertion will relieve the pressure differential.
- Pressure differential without damage to the middle or inner ear usually

resolves within a few days of returning to normal atmospheric pressure.

- Barotitis that results in injury to the middle or inner ear has a variable rate of improvement; some damage may be permanent (e.g., that to the organ of Corti), whereas other injury is reversible (e.g., that involving the TM).
- Variable outcome for auditory and vestibular symptoms and injuries to the inner ear

COMPLICATIONS

- Vertigo
- Tinnitus
- Hearing loss
- TM rupture
- Oval or round window rupture
- Hemorrhage

- H92.09 Otolgia, unspecified ear
- H93.19 Tinnitus, unspecified ear

FAQ

- Q: Is the Valsalva maneuver also effective on plane ascent?
- A: Yes. Creating even greater pressure in the middle ear by performing the Valsalva maneuver can overcome a resistant eustachian tube and result in sudden venting of increased middle ear pressure.
- Q: Can children with otitis media travel in airplanes?
- A: Yes. Weiss and Frost (1987) have shown that commercial air travel did not result in worsening of symptoms and, in fact, the presence of otitis media with effusion seemed to be protective against barotitis.
- Q: How can I minimize my child's ear pain when traveling in an airplane?
- A: For infants: Have them nurse, take a bottle, or suck on a pacifier during ascent and descent. Older children may eat or chew gum or suck on hard candies. This will result in pharyngeal movements that will repeatedly open the eustachian tube and equalize middle ear pressure to environmental pressure. Children can also be taught the Valsalva maneuver. If the child is currently experiencing a URI, use of decongestants prior to flight may be helpful.

BARTTER SYNDROME

Elaine Ku • Anthony A. Portale

BASICS

DESCRIPTION

- Bartter syndrome is a hereditary renal salt-wasting tubulopathy characterized by hypokalemic, hypochloremic metabolic alkalosis and normal or low blood pressure.
- The genetic defect is localized to the thick ascending limb of the loop of Henle.
- Timing and severity of presentation are variable depending on the type of genetic defect.
- Two phenotypes:
 - Antenatal (types I, II, and IV)
 - Associated with polyhydramnios and premature delivery
 - Presents in the first 4–6 weeks of life, often with polyuria and signs/symptoms of severe dehydration
 - Associated with hypercalciuria and nephrocalcinosis
 - Type IV is associated with sensorineural deafness.
 - Classic (type III)
 - Symptoms begin at age 2 years and diagnosis is usually made later in childhood or during adolescence.

EPIDEMIOLOGY

- Bartter syndrome is a very rare disorder.
 - Prevalence: 1 per million
 - Prevalence is higher in areas where consanguinity is common.

ETIOLOGY

- Mode of transmission: autosomal recessive except for type V which is autosomal dominant
- Five genetic subtypes and their various genetic defects:
 - Type I: sodium-potassium-chloride cotransporter (NKCC)
 - Type II: potassium channel (ROMK)

- Type III: chloride channel (ClC-Kb)
- Type IV: barttin protein
- Type V: Calcium-sensing receptor associated with autosomal dominant hypocalcemia

PATHOPHYSIOLOGY

- Mutations in NKCC, ROMK, barttin, or ClC-Kb result in the Bartter syndrome phenotype of salt wasting and hypokalemia by disrupting the molecular pathways for electrolyte transport in the thick ascending limb as described below.
- In the thick ascending limb of the loop of Henle, approximately 25% of filtered sodium chloride is reabsorbed via the sodium-potassium-2-chloride cotransporter (NKCC2), which is the target of loop diuretics such as furosemide.
- Potassium exits the cell via potassium channels (ROMK) on the apical (lumen) side of the tubule and is recycled via the NKCC2, thus permitting continued sodium chloride reabsorption.
- Chloride exits the cell and enters the bloodstream via a basolateral chloride channel (ClC-Kb) that is anchored by an accessory protein, barttin.
- A calcium-sensing receptor on the blood (basolateral) side, when activated by calcium, inhibits ROMK activity, which interferes with NKCC activity. A gain-of-function mutation in the calcium-sensing receptor results in a Bartter-like syndrome (type V).
- Calcium and magnesium are normally reabsorbed paracellularly in the thick ascending limb, driven by the lumen-positive potential that is created by sodium chloride transport across NKCC.
 - Hypercalciuria, and sometimes hypermagnesuria, occurs due to decreased paracellular transport of calcium and magnesium in the setting of salt wasting.
- Renin and aldosterone levels are typically increased (triggered by volume depletion) and contribute to metabolic alkalosis and hypokalemia.
- A functional thick ascending limb is necessary for the function of the countercurrent multiplier that is responsible for renal concentrating ability; impaired function of the thick ascending limb results in

impaired urinary concentration.

- Prostaglandin E levels are typically very elevated in Bartter syndrome.

DIAGNOSIS

HISTORY

- Dehydration
- Emesis
- Diarrhea
- Recurrent fevers
- Failure to thrive
- Polydipsia
- Polyuria
- Growth retardation
- Anorexia
- Symptoms of hypokalemia
 - Muscle weakness
 - Constipation
- Cognitive and developmental delay
- Salt craving
- Seizures
- Kidney stones (antenatal Bartter)
- History of hearing loss (antenatal Bartter)

PHYSICAL EXAM

- Constitutional: failure to thrive
- Head: large forehead
- Eyes: large eyes
- Ears: protuberant
- Face: triangular facies
- Neurologic: developmental and cognitive delay
- Skin: decreased turgor, prolonged capillary refill

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Serum electrolytes

- To identify the presence of hypochloremic metabolic alkalosis and hypokalemia
- Phosphorus level (can be low)
- Serum creatinine: to evaluate GFR
- Urine electrolytes
 - Urine chloride is typically >10 mEq/day.
 - Urine sodium and potassium are elevated.
- Urinalysis
 - Low specific gravity due to urinary concentrating defect
- Random urine for calcium/creatinine ratio
 - To detect hypercalciuria
 - Normal values are age-dependent.
- Renin level (typically elevated)
- 24-hour urine aldosterone excretion (typically elevated)

Imaging

Renal ultrasound: to determine presence of nephrocalcinosis and kidney stones

Diagnostic Procedures/Other

DIFFERENTIAL DIAGNOSIS

- Chronic or cyclical vomiting
- Chloride-losing diarrhea
- Pyloric stenosis
- Cystic fibrosis
- Diuretic abuse
- Gitelman syndrome
- Mineralocorticoid excess

TREATMENT

MEDICATION

- Sodium chloride supplementation
- Potassium chloride supplementation
- Nonsteroidal anti-inflammatory drugs (NSAIDs) such as indomethacin
- Potassium-sparing diuretic such as spironolactone to help counter

hypokalemia

- Angiotensin-converting enzyme inhibitors
- Growth hormone

ADDITIONAL TREATMENT

General Measures

- High-salt and high-potassium diet
- Adequate fluid intake to match urinary losses in the setting of salt wasting and polyuria

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Frequent monitoring of serum electrolytes
- Close follow-up of linear growth
- Monitor for signs of kidney stone.

PROGNOSIS

Can progress to chronic kidney disease or end-stage renal disease due to hypokalemia-induced interstitial disease and concurrent chronic NSAID use

CODES

ICD10

E26.81 Bartter's syndrome

FAQ

- Q: Can Bartter syndrome be treated with renal transplantation?
- A: Yes. A few cases of renal transplantation in Bartter syndrome have been described for correction of severe electrolyte disorders, growth disturbances, or treatment of chronic kidney disease.
- Q: How can vomiting be distinguished from Bartter syndrome?
- A: In vomiting, urine chloride is typically <10 mEq/L, whereas in Bartter syndrome, the urine chloride is typically much higher (typically >40 mEq/L).
- Q: How does Bartter syndrome differ from Gitelman syndrome?
- A: Gitelman syndrome is a defect of the thiazide-sensitive sodium chloride cotransporter in the distal convoluted tubule. Patients with Gitelman syndrome also present with hypokalemic metabolic alkalosis but typically have hypocalciuria in contrast to normal or increased urinary calcium in patients with Bartter syndrome. Patients with Gitelman also typically have persistent hypomagnesemia and high urinary fractional excretion of magnesium. In addition, patients with Gitelman syndrome typically have a blunted thiazide response (manifested by an increase in the fractional excretion of chloride after thiazide administration), whereas patients with Bartter syndrome will respond to thiazide diuretics
- Q: How can Bartter syndrome be distinguished from diuretic abuse?
- A: Both Bartter syndrome and diuretic abuse will present with similar electrolyte abnormalities and an elevated urinary chloride. The best test for diuretic abuse is a urinary diuretic screen.
- Q: What is the role of genetic testing in Bartter syndrome?
- A: Genetic testing is available but is currently expensive and may not include all known or as yet unrecognized mutations, which limits its use.

BELL PALSY

Stephen J. Falchek

BASICS

DESCRIPTION

- This paralysis may involve all of the modalities affected by the 7th cranial nerve:
 - Mimetic facial movement
 - Taste
 - Cutaneous sensation
 - Hearing acuity
 - Lacrimation
 - Salivation
- The most important feature in diagnosis and management of Bell palsy is the distinction between a peripheral and a central 7th nerve palsy.

EPIDEMIOLOGY

Incidence

- Annually, incidence ranges from 3/100,000 in patients <10 years to 25/100,000 in adults.
- Only 1% of cases have bilateral involvement.

PATHOPHYSIOLOGY

Nearly all cases of true Bell palsy are believed to arise from a viral infection of the facial nerve and, in particular, the geniculate ganglion.

ETIOLOGY

- Idiopathic: pregnancy-related
- Infectious
 - Herpes simplex virus 1
 - Human herpesvirus 6
 - Herpes zoster (without Ramsay Hunt syndrome)

COMMONLY ASSOCIATED CONDITIONS

- Associated illnesses can cause or predispose to an isolated facial nerve

palsy but are important to distinguish from a classic Bell palsy.

- Rubella
- Lyme disease (*Borrelia burgdorferi*)
- Epstein-Barr virus (EBV)
- Cytomegalovirus (CMV)
- Mumps
- HIV
- *Mycoplasma pneumoniae*
- Sarcoidosis

DIAGNOSIS

HISTORY

- Mastoid or retroauricular pain ipsilateral to the side of developing symptoms (40–50% of patients)
- 50% of patients will have no clear sensory prodrome.
- Bell palsy often follows some identifiable infectious illness, such as viral upper respiratory tract infection (URI) symptoms, *M. pneumoniae* infection, Lyme disease, or infectious mononucleosis. However, an identified antecedent illness is not requisite for the diagnosis.
- The onset is almost always rapid, with progression to a fairly constant state of unilateral paresis or paralysis within hours to 2–3 days.
- As the weakness progresses, the patient (and family members) may note the following:
 - Difficulty with oral motor tasks (e.g., eating and drinking) due to inability to maintain mouth closure
 - Inability to completely close the eye on the affected side (sometimes leading untrained observers to note an eyelid “droop” on the normal side due to the contrast with normal eyelid closure and movements)
 - Decreased lacrimation and eye itching and burning
 - Hyperacusis
 - Ipsilateral facial numbness (less commonly)
 - Distortion of the taste of foods (dysgeusia)
- Bilateral symptoms (<1%) are distinctly rare and suggest an alternative diagnosis, such as Guillain-Barré syndrome or other infectious,

inflammatory, or metabolic disease.

PHYSICAL EXAM

- Weakness of all muscles of mimetic facial movement is noted on the affected side.
- A classic feature of peripheral facial nerve palsies is symmetric weakness or paralysis of the upper (frontalis), middle (orbicularis oculi), and lower (orbicularis oris) muscles on voluntary and involuntary mimetic movements. Having the patient wrinkle his or her forehead/raise his or her eyebrows, close his or her eyes tightly, and bare his or her teeth or smile, respectively, tests these muscles.
- Occasionally, slow or absent spontaneous blinking on the affected side
- The corneal reflex should be decreased or absent on the affected side, but the consensual response on the unaffected side should be preserved.
- The sensory division of the 7th cranial nerve is tested by examining taste perception on the anterior tongue:
 - This is done by applying, ipsilaterally, swabs soaked in a sugar solution and a salt solution to the anterolateral aspect of the tongue, without allowing for mouth closure and dispersion of the substances to the other side. Taste sensation should be ipsilaterally decreased.
 - Despite complaints of retroauricular pain and unilateral facial “numbness,” abnormalities of cutaneous sensation typically are not verifiable by sensory testing in pure 7th nerve palsies. The presence of true diminution of sensation should raise the question of other cranial nerve involvement (e.g., 5th cranial nerve).
- Examination of the external auditory canal on both sides is crucial.
 - Vesicular lesions of the tympanic membrane indicate a zoster-associated palsy (i.e., Ramsay Hunt syndrome).
 - Purulent acute otitis media or evidence of trauma mandate aggressive antibiotic treatment and possibly urgent surgical subspecialty evaluation and imaging of the temporal bone.

DIAGNOSTIC TESTS & INTERPRETATION

Imaging

- The decision to defer medical imaging in the evaluation of a typical

Bell palsy should be based on a sound clinical history and physical examination. Unusual features should provoke thoughtful review and broader investigation where indicated.

- MRI of the head with gadolinium enhancement: recommended in cases of unusual presentation or progression (e.g., bilateral involvement, slow progression [>1 week], or other cranial nerve findings). Several small series have proposed that gadolinium enhancement of the involved 7th nerve predicts a slower or less optimal recovery.

DIFFERENTIAL DIAGNOSIS

- Trauma
 - Birth (especially forceps pressure to lateral face)
 - Congenital facial palsies should not be regarded as Bell palsy but rather symptomatic of some other cause.
 - Temporal bone/petrous bone fractures
 - Deep lacerations or trauma to parotid region
- Infection
 - Purulent acute otitis media/mastoiditis
 - Basilar meningitis
 - Petrous apicitis (Gradenigo syndrome)
 - Varicella-zoster virus (VZV; Ramsay Hunt syndrome)
 - Syphilis
 - Trichinosis
 - Tuberculosis
 - Leprosy
- Inflammatory
 - Sarcoidosis
 - Behçet disease
 - Giant cell arteritis
 - Polyarteritis nodosa
 - Guillain-Barré syndrome
 - Melkersson-Rosenthal syndrome: rare neurologic disorder characterized by recurring facial paralysis, swelling of the face and lips (usually the upper lip), and the development of folds and furrows in the tongue
- Tumors

- Cerebellopontine angle tumors, osteosarcomas, cholesteatomas, neurofibromas, lymphoma
- Hyperostosis cranialis interna, osteopetrosis
- Metabolic
 - Diabetes (nerve ischemia)
 - Hyperparathyroidism
 - Hypothyroidism
 - Porphyria
- Congenital/genetic
 - Congenital absence or hypoplasia of depressor anguli oris muscle
 - Möbius syndrome
 - Chiari malformation
 - Syringobulbia

TREATMENT

Identifying treatable causes of 7th nerve palsy (e.g., Lyme borreliosis and Ramsay Hunt syndrome) is crucial for optimizing outcome and preventing comorbidities of these illnesses.

GENERAL MEASURES

- Eye protection and lubrication: A significant risk for corneal injury is best managed by applying artificial tear solutions at least 3–4 times daily and lubricating gels (e.g., Lacri-Lube) at night. Patching and protective eyewear, during active play and sleep, is usually prescribed based on the degree of remaining eyelid closure.
- Corticosteroids: prednisone, considered only within the first 72 hours of symptoms. Recommended dose: 1 mg/kg/24 h PO (maximum 80 mg) once daily for 5 days, with a taper over the following 5 days.
- Acyclovir: Most clearly indicated for the treatment of Ramsay Hunt syndrome. It is also used empirically by some practitioners in standard Bell palsy management, although evidence for its supplementary use to corticosteroids is relatively weak; see discussion in the following text. Recommended dose: 20 mg/kg/dose q.i.d. PO for 10 days; maximum 400 mg/dose. Generally, any evidence of vesicular eruption in the ear

canal or face should be treated promptly with acyclovir, as outcomes from VZV-associated palsies are reported to be worse in general.

PHYSICAL THERAPY

The benefits of facial muscle physical therapy remain controversial. Despite an increasing number of studies, some with controls, and subsequent meta-analyses, the results are conflicting. At present, there is no incontrovertible evidence for benefit due to facial physical therapy. There is no evidence that facial physiotherapy is harmful. The decision to pursue physical therapy after Bell palsy is a matter of personal preference for the practitioner and family.

MEDICATION

- **Corticosteroids:** Recent large series and meta-analyses indicate that treatment with corticosteroids is effective in reducing the risk of incomplete recovery; however, this treatment seems to be only effective if initiated within the first 48 hours of symptoms. Furthermore, statistical significance in treatment versus placebo seems to be most evident only in patients older than 40 years. However, the occurrence of synkinesias does seem to be less likely in patients treated with steroids within 48 hours across all age groups.
- **Antivirals:** These same series suggest that there is little or no benefit to therapy with either acyclovir or valacyclovir alone and that there is at best a non-statistically significant enhancement of improvement when used in combination with corticosteroids. The best evidence for added efficacy of antivirals in combination with corticosteroids seems to be in cases with particularly severe degrees of paralysis or in cases with suspected herpes zoster infection.
- **Antibiotics:** In areas where Lyme disease is endemic, many practitioners will begin treatment with oral antibiotics presumptively, while awaiting serologies (recall that the IgM titer is the most useful in the acute setting). (See “[Lyme Disease](#)” chapter.)

First Line

- Prednisone, 60–80 mg/24 h PO once daily for 5 days, with a subsequent taper over 5 days; total treatment course 10 days; must be initiated in the first 48 hours for significant results

- Amoxicillin, 50 mg/kg/24 h PO divided in 3 doses for 21–28 days, when Lyme disease suspected

Second Line

- For presumed Lyme disease:
 - Patients >8 years: doxycycline, 100 mg PO b.i.d. for 21–28 days
 - Patients of all ages: cefuroxime, 30 mg/kg/24 h PO in 2 divided doses for 21–28 days
- In cases where zoster infection is suspected or with particularly severe paralysis at onset:
 - Valacyclovir, 20 mg/kg/dose (max 1 g/dose) divided t.i.d. for 5 days (as adjunct to corticosteroids; treatment guidelines not well-established)

SURGERY/OTHER PROCEDURES

Surgical decompression: Previously, surgical decompression of the 7th nerve had been proposed as a possible treatment in cases where recovery was delayed or the clinical course more severe. No clinical evidence to support the benefit of this strategy has emerged. Surgical decompression is best reserved for “other” cases of facial nerve palsy in which there is a definable syndrome of nerve compression due to extrinsic factors, such as exostoses, tumor, etc.

ISSUES FOR REFERRAL

Subspecialty consultation: In general, patients are referred if their recovery time is prolonged or if there is a relapsing pattern or other deviations from the expected course. However, the presence of other questionable cranial nerve involvement, recent trauma, meningeal symptoms, or neurologic findings (e.g., eye movement abnormalities, acute hemiparesis, etc.) should be viewed with great concern and evaluated in an urgent care setting.

ONGOING CARE

DIET

There are no dietary restrictions that affect the outcome of Bell palsy.

PATIENT EDUCATION

Minimizing risk for injury to the cornea ipsilateral to the facial palsy may require either restricting some activities where debris or contusions to the eye are likely or wearing protective eyewear during such activities (e.g., beach activities and competitive sports). These restrictions only need to be in effect so long as there is inadequate closure of the eyelid on the affected side.

PROGNOSIS

- 60–70% full-recovery rate from isolated 7th nerve palsy
- Signs of recovering function (generally improving control of mimetic movement) are typically apparent by the 3rd week after onset.
- Prognosis for recovery seems to be worse with either a secondary deterioration in function after 2–4 days, no signs of recovery after 3 weeks, or demonstrated gadolinium enhancement of the affected facial nerve on MRI.
- Of patients with less than total recovery, many will experience at least partial return to normal function; cosmetic results vary in this group.
- Outcome of idiopathic facial palsy as a pregnancy complication seems to be less favorable (~55% full recovery).
- Up to 7% of patients may experience a 2nd occurrence at some point in the future.

COMPLICATIONS

- Corneal injury, due to decreased lacrimation and poor eye closure
- Several sequelae, generally related to aberrant reinnervation of affected end organs, are observed after an episode of Bell palsy.
 - Various synkinesias (abnormal involuntary movements that accompany a normally executed voluntary movement), including the Marin–Amat phenomenon (spontaneous eye closure with mouth opening, or its converse)
 - Blepharospasm, hemifacial spasm, facial contractures
 - The “crocodile tears” phenomenon (eating provokes ipsilateral tearing) results from crossed reinnervation between lacrimal and salivary parasympathetic fibers.

CODES

ICD10

G51.0 Bell's palsy

FAQ

- Q: How does one differentiate between peripheral facial nerve palsy and a CNS lesion?
- A: A critical step in diagnosis is the differentiation of peripheral from central (upper motor neuron) lesions. With upper motor neuron lesions (above the level of the 7th nerve nucleus), there is preferential weakness of lower facial musculature and, sometimes, differential paresis of voluntary versus spontaneous emotional mimetic movements. Brainstem lesions, on the other hand, may produce a

peripheral-appearing lesion but almost always have involvement of other pathways and cranial nerve nuclei, for example, ipsilateral lateral rectus palsy and contralateral somatic hemiplegia (Millard–Gubler syndrome).

BEZOARS

Andrew B. Grossman

BASICS

DESCRIPTION

- Accumulation of foreign material in the gastrointestinal (GI) tract
- Commonly divided into 3 categories based on the substances from which the bezoar is derived:
 - Phytobezoar (from vegetables/fruits)
 - Trichobezoar (hair)
 - Lactobezoar (milk/formula)
- Documented to occur in humans for more than 2 millennia, suggesting formation of bezoars may have been/still be culturally important for certain societies

EPIDEMIOLOGY

- Phytobezoars occur almost exclusively in adults.
- 90% of trichobezoars occur in female patients younger than 20 years of age.
- Lactobezoars occur mostly in premature, low-birth-weight infants.

PATHOPHYSIOLOGY

- Trichobezoars
 - Associated with mental retardation, pica, trichotillomania, and trichophagia; may ingest own hair but also rugs and animal or doll hair
 - Most cases of trichophagia do not result in bezoar formation (~1%).
 - History of trichophagia is obtained in only 50% of cases.
 - Retention and accumulation of hair strands in the gastric folds
 - Trichobezoars may become large and form a cast in the stomach leading to abdominal mass.
 - Bezoar may extend through the pylorus into the small bowel. This “tail” may obstruct the ampulla of Vater, leading to jaundice and pancreatitis. This phenomenon is commonly referred to as Rapunzel

syndrome.

- **Phytobezoars**
 - Most common form among adults, rare in children
 - Associated with gastric dysmotility and poor gastric emptying (either primary or following gastric surgery) and hypochlorhydria
 - Composed primarily of cellulose, hemicellulose, lignins, and tannins
- **Lactobezoars (milk)**
 - Most often reported in premature, low-birth-weight infants being fed high-calorie premature formula (although there are reports in full-term infants and exclusively breastfed infants)
 - Factors contributing to lactobezoar formation include the following:
 - Formulas with high casein content
 - Early and rapid feeding advancement in small infants
 - High-caloric-density formulas
 - Formulas with high calcium/phosphate content
 - Continuous tube feedings
 - Altered gastric motility in low-birth-weight infants

ETIOLOGY

Classification of bezoars is dependent on the most prominent substance from which they are formed, including:

- **Trichobezoars:** hair, carpet
- **Phytobezoars:** indigestible fruit and vegetable matter
- **Lactobezoars:** milk
- **Less common materials include the following:**
 - Foreign bodies
 - Gallstones
 - Medications, including vitamins, antacids, psyllium, sucralfate, cimetidine, and nifedipine
- **Can occur in cystic fibrosis (CF) patients after lung transplantation**
- **Colonic and rectal bezoars**
 - Due to indigestible sunflower seeds, popcorn, and gum have been reported in children and adults
 - These usually present with obstruction, although encopresis and colitis-type symptoms have been described.

DIAGNOSIS

HISTORY

- Signs and symptoms of bezoar formation include the following:
 - Pain
 - Halitosis
 - Nausea
 - Vomiting
 - Diarrhea
 - Gastric ulceration
 - Upper GI bleeding and perforation
 - Left upper quadrant mass
- Trichobezoars
 - Unusual patterns of balding
 - Palpable left upper quadrant mass in the abdomen is often detected.
 - Hair found in the stool
- Phytobezoars
 - Abdominal mass is palpable in <50% of patients.
- Lactobezoars
 - Abdominal distention, diarrhea, emesis, and increased gastric residuals

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Iron deficiency anemia
- Presence of steatorrhea or protein-losing enteropathy

Imaging

- Plain abdominal x-ray
 - Heterogenous intragastric mass that could be mistaken for food-filled stomach
- Upper GI barium studies
 - May identify and outline the mass
- Ultrasound and CT can also be helpful.

Diagnostic Procedures/Other

Endoscopy allows for direct visualization and elucidation of composition of bezoar.

DIFFERENTIAL DIAGNOSIS

Any gastric foreign body can mimic a gastric mass and may present on palpation.

TREATMENT

GENERAL MEASURES

- Trichobezoars
 - Difficult to remove endoscopically, attempts to fragment may result in migration and small bowel obstruction
 - Treatment is usually surgical removal: Trichobezoars are normally large and hair is not dissolvable.
- Phytobezoars
 - Medications such as prokinetic agents to stimulate gastric motility
 - Enzyme therapy to help dissolve the material
 - N-acetylcysteine treatment via nasogastric tube has been documented in one case report.
 - Endoscopic fragmentation or extraction
 - Coca-Cola administration with or without endoscopic extraction has been reported to be effective.
 - Surgical extraction
 - Diet alteration
- Lactobezoars
 - Withholding feedings for 48 hours while the patient is sustained on intravenous (IV) fluids will resolve most lactobezoars.
 - Gentle gastric lavage may be helpful.

- T18.2XXA Foreign body in stomach, initial encounter
- T18.3XXA Foreign body in small intestine, initial encounter

FAQ

- Q: What are some commonly used medications that can lead to bezoar formation?
- A: Vitamins, antacids, psyllium, sucralfate, cimetidine, and nifedipine
- Q: What may place an infant at risk for formation of a bezoar?
- A: The literature suggests that formulas with high casein content may be linked with lactobezoar formation. Other possible contributing factors include early and rapid feeding advancement in small infants, high-density formulas, formulas with a high calcium/phosphate content, continuous tube feedings, and altered gastric motility in low-birth-weight infants.

BILIARY ATRESIA

Greggy D. Laroche • Douglas B. Mogul

BASICS

DESCRIPTION

Biliary atresia (BA) is a congenital disease characterized by fibrosis, obstruction, and obliteration of the biliary system that is universally fatal without intervention.

EPIDEMIOLOGY

- BA accounts for approximately 30% of cases of neonatal cholestasis.
- BA is the most common cause of persistent cholestasis in infants and children and the most frequent indication for pediatric liver transplantation.
- The disease affects 1:8,000 to 1:18,000 live births.

RISK FACTORS

Genetics

- No single genetic mutation has been identified as the sole cause of BA, and there is no clear pattern of inheritance.
- Genes influencing morphogenesis may contribute to pathophysiology.

PATHOPHYSIOLOGY

- Biliary obstruction begins at, or near, the time of birth and progresses throughout early infancy, leading to damage and ultimately scarring of liver parenchyma.
- Approximately 20% of biliary patients have at least one other major congenital anomaly (i.e., embryonal form) including splenic malformation, interrupted inferior vena cava, midline liver, situs inversus, preduodenal portal vein, and intestinal malrotation.
- More common form is the perinatal form that is not associated with malformations.

ETIOLOGY

Etiology is not completely defined, but many different pathogenic

mechanisms have been proposed, including the following:

- Perinatal infection of the liver and biliary tract with potential organisms including cytomegalovirus, rotavirus, and reovirus
- Immune dysregulation
- Defective morphogenesis
- Environmental toxin exposure
- Vascular insufficiency

DIAGNOSIS

HISTORY

- Newborns appear healthy at birth with good growth and development. However, jaundice of the skin and eyes persists beyond the 2-week interval of physiologic jaundice. Acholic stools and dark urine may be noted.
- In addition, infants with BA may present with poor weight gain, bleeding (due to vitamin K deficiency), and/or increased stool frequency.

PHYSICAL EXAM

- Jaundice can be seen in the eyes, skin, or buccal mucosa.
- Infants may have hepatomegaly and splenomegaly.
- Rectal exam, including digital exam, may reveal acholic stools.

SCREENING

- An infant stool color card that identifies acholic and normal stool has been used in Taiwan, where it was shown to decrease the time to diagnosis in BA and improve outcomes for children with BA.
- Infants with BA have elevated direct bilirubin at 24 hours of life, suggesting a potential role for screening with this blood test.

ALERT

- One of the most important factors determining outcomes in BA, including survival and need for transplantation, is the age at which a patient is referred for workup.
- The 10-year survival rate of patients diagnosed and treated prior to 60

days versus after 90 days is 73% and 11%, respectively.

DIAGNOSTIC TESTS & INTERPRETATION

Initial Lab Tests

- Conjugated hyperbilirubinemia (defined as a conjugated fraction >2 mg/dL or a conjugated bilirubin >20% of the total bilirubin) may be elevated as early as the first 24 hours of life.
- Additional laboratory findings may include mild to moderate elevations in AST, ALT, and alkaline phosphatase as well as significant elevations in γ -glutamyltransferase (GGT)
- Additional diagnostic testing should be done as clinically indicated.
- Bacterial cultures (blood, urine, stool), viral studies (hepatitis B, hepatitis C, Epstein-Barr virus, toxoplasmosis, other viruses, rubella, cytomegalovirus, herpes virus [TORCH] infections, HIV, adenovirus, enterovirus)
- Metabolic profiles (plasma amino acids, urine organic acids and urine succinylacetone, lactate/pyruvate ratio)
- Serum alpha-1-antitrypsin level and phenotype
- Thyroid function tests (TSH, free T₄)
- Urine-reducing substances to evaluate for galactosemia (if infant has taken breast milk or lactose-containing formula)
- CBC, coagulation studies (prothrombin time/international normalized ratio/partial thromboplastin time [PT/INR/PTT]), total protein, albumin, and fat-soluble vitamins

Imaging

- Abdominal ultrasound
 - Should be obtained to rule out choledochal cyst but has poor sensitivity and specificity for BA unless “triangular chord” sign seen (80% sensitive, 98% specific)
 - May also assist in defining embryonal versus perinatal form
- Hepatobiliary iminodiacetic acid (HIDA) scan/hepatobiliary scintigraphy can be obtained to evaluate biliary excretion.

Additional Testing

- Discussion with pediatric gastroenterologist should be obtained following evidence of persistent cholestasis.

- Liver biopsy: In BA, findings may include bile duct proliferation, bile stasis, periportal inflammation, and periportal fibrosis.
- Sweat chloride test (cystic fibrosis)
- Ophthalmology exam for Alagille syndrome (posterior embryotoxon) and congenital infections
- Spine film to evaluate butterfly vertebrae of Alagille syndrome
- Echo to evaluate cardiac anomalies in Alagille syndrome
- Urine bile acid analysis
- Intraoperative cholangiogram
 - Gold standard for diagnosis of BA but is an invasive test
 - Reserved for individuals with high suspicion of BA.

DIFFERENTIAL DIAGNOSIS

- Intrahepatic
 - Infection: sepsis, UTI, gastroenteritis, TORCH infections, HIV, viral hepatitis (A, B, C, D, E), Epstein-Barr virus, adenovirus, coxsackie B virus, echovirus, enterovirus
 - Systemic disease: panhypopituitarism, congestive heart failure, ischemic hepatopathy, trauma
 - Metabolic: galactosemia, tyrosinemia, alpha-1-antitrypsin, cystic fibrosis, citrin deficiency, respiratory chain disorders, hereditary fructose intolerance, disorders of bile acid synthesis, storage disorders, neonatal iron storage disease
 - Genetic: Alagille syndrome, Zellweger syndrome, Down syndrome, Turner syndrome
 - Progressive familial intrahepatic cholestasis (i.e., PFIC 1, 2, and 3)
 - Toxins and drugs: total parenteral nutrition, antibiotics, and other medications
 - Miscellaneous: neonatal hepatitis, neonatal lupus, congenital hepatic fibrosis, Caroli syndrome, inspissated bile syndrome, histiocytosis X
- Extrahepatic
 - Choledochal cyst
 - Choledocholithiasis
 - Neonatal sclerosing cholangitis
 - Tumor/mass compression
 - Spontaneous perforation of common bile duct

TREATMENT

SURGERY/OTHER PROCEDURES

- A hepatoportoenterostomy (Kasai procedure) is the only effective therapy for BA other than a liver transplant. The goal of the Kasai procedure is to restore bile flow from the liver to the intestine.
- Despite the Kasai procedure, 70–80% of patients with BA ultimately require liver transplantation.
 - At 3 months after Kasai procedure, a total serum bilirubin <2 mg/dL is associated with low likelihood of requiring hepatic transplant within 2 years.
 - A total serum bilirubin ≥ 6 mg/dL is associated with failure of adequate bile flow and higher likelihood of need for liver transplantation.
- Indications for transplantation include the following:
 - Synthetic dysfunction of the liver
 - Complications of portal hypertension (PHTN) such as life-threatening hemorrhage, ascites, and spontaneous bacterial peritonitis
 - Persistent cholestasis with impaired quality of life such as intractable pruritus
 - Recurrent cholangitis

ALERT

- Without surgical intervention, 50–80% of patients with BA will die from biliary cirrhosis by 1 year of age and 90–100% by 3 years of age.
- If diagnosed within the first 3 months of life, surgical therapy can successfully restore bile flow from liver into the intestinal tract in 30–80% of patients.

MEDICATION

- After the Kasai operation, patients receive
 - Ursodeoxycholic acid to promote bile flow
 - Supplemental fat-soluble vitamins
 - Oral prophylactic antibiotics to prevent ascending cholangitis
- Corticosteroids have not been shown to improve outcomes in patients

with BA.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

In conjunction with a GI specialist, obtain routine serum biomarkers including CBC, liver function tests, and GGT to determine progression of disease. Physicians should also monitor closely fat-soluble vitamins as well as coagulation studies to evaluate liver function including production of clotting factors and absorption of vitamin K.

DIET

- Anthropometrics should be performed consistently and frequently to evaluate growth as patients tend to have decreased fat stores and decreased lean body mass.
- For individuals with poor weight gain on breast milk or receiving standard formula supplementation, patients should use formulas enriched with medium-chain triglycerides because these fats do not require bile for absorption.
- If patients exhibit poor weight gain on oral feedings, an enteric feeding tube for supplemental nutrition should be strongly considered.
- Due to decrease bile acid excretion, patients with BA malabsorb fat-soluble vitamins (A, D, E, and K) and likely need supplementation.

COMPLICATIONS

- Ascending bacterial cholangitis: Patients are predisposed to this infection after the portoenterostomy procedure given the absence of the ampulla of Vater and present with fever, elevated liver function tests, hypopigmented stools, increased pruritus, and/or increased GGT. Recurrent ascending cholangitis can lead to sclerosis and loss of remaining intrahepatic bile ducts. Antibiotic prophylaxis is helpful in preventing recurrent infections.
- Pruritus: Occurs frequently and is due to elevated circulating bile acid. Ursodeoxycholic acid, antihistamines, rifampin, naloxone, and cholestyramine may be used to alleviate itching.
- Ascites: Spironolactone, chlorothiazide, and furosemide are commonly

used diuretics. However, their use should be monitored closely in order to avoid the development of hepatorenal syndrome.

- PHTN: Monitoring liver firmness, texture, and span along with splenomegaly will be helpful. Progressive thrombocytopenia suggests further splenomegaly. PHTN can also manifest as ascites, spontaneous bacterial peritonitis, portosystemic encephalopathy, portopulmonary syndrome, or GI hemorrhage from esophageal or gastric varices.

CODES

ICD10

- Q44.2 Atresia of bile ducts

- K83.1 Obstruction of bile duct
- R16.0 Hepatomegaly, not elsewhere classified

FAQ

- Q: How soon should parents contact their primary care provider when they see pale-colored stools?
- A: The first time they notice these stools are acholic.
- Q: What should a physician do if he or she is concerned about persistent jaundice?
- A: Obtain a thorough history, perform a thorough physical exam, and measure both total and direct bilirubin. If there is significant conjugated bilirubinemia, contact your local pediatric gastroenterologist and begin neonatal cholestasis diagnostic workup, ruling out the most immediately dangerous etiologies (including potentially fatal metabolic diseases and infections) as well as common etiologies such as BA.

BLASTOMYCOSIS

Evan J. Anderson

BASICS

DESCRIPTION

- Systemic infection caused by the dimorphic soil fungus *Blastomyces dermatitidis*
- Dimorphism is characterized by a mold phase (mycelial form) that grows at room temperature and a yeast form that grows at body temperature.
- Incubation period estimated at 30–45 days

EPIDEMIOLOGY

- Similar to other dimorphic fungi, *B. dermatitidis* is a soil saprophyte (mycelial form).
- Congenital infections occur rarely.
- Infection is endemic in the upper Midwest and Southern United States, particularly in the wooded Mississippi and Ohio River valleys and the Great Lakes. The highest incidence in the United States is in Wisconsin, Mississippi, and Tennessee followed by Minnesota, Illinois, North Dakota, Alabama, and Louisiana.
- Substantial disease occurs in the Canadian provinces of Manitoba and northwestern Ontario. Other reported areas of infection include Africa, India, and South America.
- Children account for 3–11% of all cases of blastomycosis.
- Blastomycosis is a very uncommon diagnosis even in endemic regions.

RISK FACTORS

- Blastomycosis is more common in males. This is thought to be due to occupational or recreational activities that increase risk of exposure.
- Underlying immunodeficiency is rarely observed among children with blastomycosis.

GENERAL PREVENTION

- No special precautions for hospitalized patients are indicated.
- The natural reservoir is undetermined.

PATHOPHYSIOLOGY

- Inhalation of the fungus into the lung is followed by an inflammatory response with neutrophils and macrophages.
- Blastomycosis most commonly presents as sub-acute pulmonary disease, but the clinical spectrum of the disease extends from asymptomatic to disseminated disease that can involve lung, skin, bone, and central nervous system (CNS).
- As many as 50% of infections are asymptomatic.

ETIOLOGY

- Infection is almost always caused by inhalation of spores from *B. dermatitidis*.
- Rarely, blastomycosis has occurred through accidental inoculation, dog bites, conjugal transmission, and intrauterine transmission.
- Point-source outbreaks have occurred with occupational and recreational activities that occur in areas with moist soil and decaying vegetation, such as along streams and rivers.
- Natural infection occurs in humans and dogs.

COMMONLY ASSOCIATED CONDITIONS

- Pulmonary blastomycosis
 - Most common form of infection by *Blastomyces* in children
 - Can be acute, subacute, or chronic
 - Illness severity can vary greatly, from asymptomatic to upper respiratory tract infection, bronchitis, pleuritis, pneumonia, or severe respiratory distress.
- Cutaneous blastomycosis
 - Skin manifestations are variable and include nodules, verrucous lesions, subcutaneous abscesses, or ulcerations.
 - Cutaneous disease usually occurs after pulmonary infection with dissemination to the skin, rarely by direct inoculation.
- Bone blastomycosis
 - Bone disease usually occurs after pulmonary infection with dissemination to the bone resulting in osteomyelitis and bone

destruction.

- Disseminated blastomycosis
 - Recent series suggest that this occurs in less than 1/2 of children
 - Usually begins as pulmonary infection, with subsequent spread to involve skin, bone, genitourinary tract, and/or CNS.
 - Can disseminate to virtually any organ
 - The classic triad of lung, bone, and skin disease occurs in $\leq 15\%$ of children.

DIAGNOSIS

HISTORY

- History of residence or travel to an endemic area is very important.
- For children with acute pulmonary blastomycosis, the most common presenting symptoms are the following:
 - Cough (may be productive)
 - Fever
 - Chest pain
 - Malaise
- Children with chronic pulmonary disease present with the following:
 - Chronic (>2 weeks) nonproductive cough
 - Pleuritic chest pain
 - Poor appetite
 - May also be a history of fever, chills, weight loss, fatigue, night sweats, or, rarely, hemoptysis

PHYSICAL EXAM

- Initial pulmonary infection may present with physical exam findings similar to those of bacterial pneumonia.
- Respiratory signs and symptoms often have resolved by the time cutaneous manifestations are apparent.
- Skin involvement appears as nodules, nodules with ulceration, or granulomatous lesions.
- Bone involvement usually presents with progressive focal pain and point tenderness.

DIAGNOSTIC TESTS & INTERPRETATION

Diagnostic Procedures/Other

- Definitive diagnosis requires the growth of *B. dermatitidis* from a clinical specimen. In the cooler temperature at which fungal culture is performed in the laboratory, *B. dermatitidis* usually switches back to the mold form.
- Direct visualization of the yeast form may be performed on samples of sputum, urine, cerebrospinal fluid, bronchoalveolar lavage sample, or tissue biopsy.
- Although the most accurate serologic test is the enzyme immunoassay, all serologic tests have poor sensitivity and specificity.
- An assay to detect *Blastomyces* antigen in urine is available and is about 93% sensitive. Cross-reactivity occurs in patients with histoplasmosis, paracoccidioidomycosis, and *Penicillium marneffei* infections.
- Chest radiography commonly reveals lobar consolidation. Cavitation, fibronodular patterns, mass, and mass effect may also be seen.

DIFFERENTIAL DIAGNOSIS

- Acute bacterial infection
- Neoplasm
- Tuberculosis
- Sarcoidosis
- Other fungal infections causing pneumonia (e.g., histoplasmosis)

TREATMENT

MEDICATION

- Although acute pulmonary infections may resolve without treatment, the high rate of progression to extrapulmonary disease leads many experts to recommend treatment for all cases of blastomycosis.
- Mild or moderate pulmonary or extrapulmonary disease
 - Oral itraconazole
 - Alternative agents include fluconazole or voriconazole.
- Severe pulmonary disease, other severe infection, or

immunosuppression

- IV amphotericin B: Many experts prefer a lipid formulation of amphotericin B over amphotericin B deoxycholate.
- Therapy may be switched to oral itraconazole after clinical stabilization with amphotericin B.
- CNS blastomycosis
 - Lipid formulation of amphotericin B at 5 mg/kg/day over 4–6 weeks, followed by an oral azole
- During pregnancy
 - IV amphotericin B
 - Azoles should be avoided owing to potential teratogenicity.
- Length of therapy is site dependent:
 - ≥ 6 months or longer for pulmonary disease
 - ≥ 12 months or longer for bone or CNS disease
- Lifelong suppressive therapy with oral itraconazole may be required for immunosuppressed patients and in patients who experience relapse despite appropriate therapy.
- Voriconazole, a newer azole, has in vitro activity against *B. dermatitidis* and penetrates the CSF better than itraconazole. Anecdotal reports support its use as an option for step-down therapy for CNS infection.

SURGERY/OTHER PROCEDURES

Occasionally, drainage of abscesses and debridement of bone are necessary.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- All azoles can cause hepatitis. Thus, hepatic enzymes should be measured before starting therapy, 2–4 weeks after therapy has begun, and every 3 months during therapy.
- All azoles interact with P450 enzymes. Consider drug–drug interactions when the patient is taking other medications.

- Itraconazole capsules are poorly absorbed; the oral solution is poorly tolerated due to taste. Monitoring adherence to therapy is important and many recommend following itraconazole levels.
- Amphotericin B commonly causes acute kidney injury and electrolyte wasting (particularly potassium and magnesium). Infusion-related toxicity is also common. Lipid formulations are typically better tolerated than the deoxycholate.

PROGNOSIS

- Before antifungal medications were available, the mortality associated with blastomycosis was up to 90%.
- Appropriate treatment with antifungal medications results in excellent cure rates and mortality rates of <10%.
- Worse outcomes tend to occur in association with a delay between onset of symptoms and establishment of a diagnosis.

COMPLICATIONS

- Dissemination is the main complication of the infection, occurring in less than 50% of children with blastomycosis.
- Residual orthopedic issues can persist in children with bone involvement.
- Systemic infection may be well advanced before symptoms are noted, requiring long-term therapy and follow-up.

ICD10

- B40.9 Blastomycosis, unspecified
- B40.2 Pulmonary blastomycosis, unspecified
- B40.7 Disseminated blastomycosis

FAQ

- Q: When should I suspect blastomycosis?
- A: Consider blastomycosis in a child with exposure to an endemic blastomycosis area that is presenting with subacute to chronic pneumonia. Oftentimes, these children will have been treated with multiple prior antibiotics and have ongoing or progressive pneumonia or develop skin or bone lesions.
- Q: Blastomycosis is on my differential; how can I best test for it?
- A: The urine antigen test is the most sensitive test for the detection of blastomycosis but can be falsely positive. Usually, a clinical specimen is ultimately needed to establish a diagnosis.
- Q: I have a child hospitalized with blastomycosis; should I start with itraconazole or amphotericin B?
- A: If the child is not in the ICU, is not acutely worsening, and is able to take itraconazole by mouth, then it is reasonable to start with itraconazole. Itraconazole is generally much better tolerated than are amphotericin B formulations.

BLEPHARITIS

Prina P. Amin • Erika Abramson

BASICS

DESCRIPTION

- Inflammatory or infectious process of the eyelid margin, typically involving skin, lashes, and meibomian glands
 - Associated with itchiness, redness, flaking, and crusting of the eyelids
 - Usually chronic, intermittent with exacerbations and remissions
 - Typically bilateral
 - No universal classification system
- Historically classified according to location, anterior versus posterior
 - Anterior blepharitis: affects the base of the eyelashes and eyelash follicles
 - Posterior blepharitis: affects the meibomian glands
- Can also be classified by etiology
 - Inflammatory: seborrheic, meibomian gland dysfunction, allergic, associated with rosacea
 - Infectious: bacterial (most commonly *Staphylococcus aureus* or *Staphylococcus epidermidis*), viral, fungal, or parasitic

EPIDEMIOLOGY

- One of the most common ocular disorders
 - Presents in patients of all ages
 - Mean age of presentation is age 50 years.
 - No gender differences seen.

RISK FACTORS

- Presence of atopic, allergic, or seborrheic dermatitis
- Rosacea
- Tear deficiency and dysfunction
- Contact lens use
- Isotretinoin used to treat severe cystic acne

- Less common risk factors include underlying immunologic disorders such as lupus, eyelid tumors, trauma, and other dermatoses.

PATHOPHYSIOLOGY

- Complex and results from the interplay between abnormal lid margin secretions, lid margin organisms, and dysfunction of the tear film
- Infectious blepharitis: Bacteria such as *Staphylococcus* may cause direct infection of the eyelids, evoke reaction to the exotoxin, or provoke an allergic reaction to the staphylococcal antigens.
- Inflammatory blepharitis: Inflammation of the meibomian glands leads to impaired gland secretions and instability of the tear film.
- This condition can have a direct toxic effect and promote bacterial overgrowth.

COMMONLY ASSOCIATED CONDITIONS

- Seborrheic dermatitis
- Allergic or contact dermatitis
- Down syndrome (trisomy 21)
- Ocular rosacea
- Dry eye (keratoconjunctivitis sicca)
- Hordeolum
- Chalazion

DIAGNOSIS

SIGNS AND SYMPTOMS

- Redness of eyelid margin
- Irritation
- Burning
- Tearing
- Gritty sensation
- Dry or watery eyes
- Increased blinking
- Loss of eyelashes
- Photophobia
- Contact lens intolerance

- Eye discharge or crust, particularly along lashes
- Eyelid sticking, especially in the morning

HISTORY

- Duration of symptoms: Blepharitis is often chronic, with periods of exacerbation and remission.
- Symptoms and signs of systemic disease
- Current and previous systemic and topical medications (in particular: antihistamines, drugs with anticholinergic effects, and isotretinoin)
- Contact lens use
- Exacerbating conditions such as eye makeup use, smoke, allergens
- Previous intraocular or eyelid surgery
- Trauma
- Past medical and family histories of atopy
- Recent exposure to lice

PHYSICAL EXAM

- Use a focused direct light source to carefully evaluate the eyelids for abnormal eyelid position, eyelash loss, hyperemia of the eyelid margins, abnormal deposits at the base of the eyelids, ulceration, vesicles, scaling, chalazion/hordeolums, and scarring.
- Examine the conjunctiva and sclera to look for signs of inflammation, which warrants a slit-lamp examination.
- Assess visual acuity.
- Perform a general exam looking for signs of systemic disease such as seborrhea, atopic dermatitis, rosacea, and lupus.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Diagnosis is made clinically. There are no specific diagnostic tests to confirm the diagnosis of blepharitis.
- In refractory cases or cases of recurrent anterior blepharitis with severe inflammation, cultures of the eyelid margins may be useful.

DIFFERENTIAL DIAGNOSIS

- Acute conjunctivitis (bacteria, viral, or allergic)
- Atopic or contact dermatitis

- Keratitis
- Iritis
- Glaucoma
- Chemical burn
- Corneal abrasion
- Foreign body
- Hordeolum
- Chalazion
- Lice
- Trichotillomania

TREATMENT

GENERAL MEASURES

- Several treatments may be helpful and are generally used in combination.
- Treatments may provide symptomatic relief but usually do not result in cure for chronic cases.
- Treatments include the following:
 - Warm compresses
 - Eyelid hygiene
 - Antibiotics (topical and/or systemic)
 - Topical short course anti-inflammatory agents
- Warm compresses should be applied for 15 minutes at least twice daily to loosen crusts.
- Eyelid hygiene
 - Consists of massaging the eyelid margins daily and carefully removing the crusts using cotton swabs, cotton balls, commercial eyelid scrubs, and/or diluted baby shampoo
 - Children should be instructed to avoid rubbing their eyes if possible and to wash hands frequently.
- Wearing contact lens or eye makeup should be avoided during exacerbations.
- Activities that result in decreased blinking can dry out the eye and worsen exacerbations. Such activities may include television watching

and use of computers or video games.

MEDICATION

- Warm compresses and eyelid hygiene are the traditional mainstay of therapy.
- Medications can be added in conjunction with conservative measures.
- A topical antibiotic ophthalmic ointment (such as bacitracin or erythromycin) may be applied 1–4 times daily until inflammation resolves.
- A brief course of topical corticosteroids are generally reserved for severe inflammation and in cases of severe conjunctival injection or marginal keratitis.
- The minimal effective dose of corticosteroid should be used and for as short a time as possible.
- Long-term use of oral antibiotics (such as erythromycin or tetracyclines) may be useful in severe cases.

ISSUES FOR REFERRAL

- Moderate or severe pain
- Vision loss
- Severe or chronic redness
- Corneal involvement
- Traumatic eye injury
- Recent ocular surgery
- Distorted pupil
- Recurrent episodes
- More severe eyelid inflammation with nodular mass, ulceration, or extensive scarring
- Lack of improvement with conservative measures and topical antibiotics

ONGOING CARE

- No additional care is needed if symptoms resolve completely.
- Patients should be educated about the potential for recurrence and chronicity with blepharitis.

- Warm compresses and eyelid hygiene treatment may be required long term.

CODES

ICD10

- H01.009 Unspecified blepharitis unspecified eye, unspecified eyelid
- H01.019 Ulcerative blepharitis unspecified eye, unspecified eyelid
- L21.8 Other seborrheic dermatitis

FAQ

- Q: Is blepharitis contagious?
- A: Blepharitis is not contagious. However, if blepharitis is due in part to bacterial infection, the bacteria can be transmitted to other family members and result in conjunctivitis. Thus, good hand hygiene is important.
- Q: Will the child outgrow this?
- A: Although some children may be cured, for many, blepharitis is a chronic condition in which symptomatic control is the goal.
- Q: Is blepharitis common in children?
- A: Although blepharitis can occur in patients of all ages, it tends to be

seen much more frequently in adults.

BONE MARROW AND STEM CELL TRANSPLANT

Justin T. Wahlstrom • Biljana N. Horn

BASICS

DESCRIPTION

- Hematopoietic stem cell transplantation (HSCT) is the infusion of progenitor stem cells with the intention of restoring hematopoiesis and immunity. HSCT can be classified by
 - Donor type: syngeneic (derived from an identical twin), allogeneic (derived from a related or unrelated donor), or autologous (derived from the patient prior to stem cell-toxic therapy)
 - Product type
 - ▢ Bone marrow transplantation (BMT): Stem cells are obtained by harvesting bone marrow under anesthesia.
 - ▢ Peripheral blood stem cell transplantation (PBSCT): Stem cells are mobilized to the periphery with cytokines (GCSF) and collected by apheresis.
 - ▢ Umbilical cord blood transplantation (UCBT): Stem cells are collected from the umbilical cord and placenta following delivery.
- Stem cells are infused in the peripheral blood of the recipient using a central venous catheter, similar to a blood transfusion. They then home to the bone marrow niche and over the next 2–4 weeks differentiate into mature blood components.

EPIDEMIOLOGY

- In 2010, 1,479 pediatric allogeneic (and 782 autologous) HSCTs were performed in the United States. Approximately 40% of allogeneic transplants are from matched related donors.
- The use of unrelated PBSCT and unrelated UCBT has been gradually increasing since the late 1990s, whereas the use of related BMT/PBSCT has remained stable. The use of unrelated BMT has been

steadily decreasing.

TREATMENT

INDICATIONS

- HSCT is typically used to provide stem cell rescue following myeloablative therapy (cancers), to provide new stem cells to correct an intrinsic cellular defect (inborn errors of metabolism, other stem cell defects), or to alter the immune system to improve or correct an immunologic defect (e.g., autoimmune disease).
- Examples of diseases for which HSCT can be beneficial include the following:
 - Leukemia (ALL, AML, JMML, and CML)
 - High-risk ALL (indications for transplant include lack of response to chemotherapy or early relapse)
 - High-risk AML (indication based on cytogenetic markers, response to therapy, or early relapse)
 - All JMML patients require HSCT for cure.
 - CML only if not well-controlled on tyrosine-kinase inhibitor therapy (imatinib, dasatinib)
- Solid tumors (lymphoma, neuroblastoma, brain tumors, some sarcomas)
- Severe primary immunodeficiencies (SCID, WAS, CGD, hyper IgM, XLP, Chediak-Higashi syndrome, Griscelli syndrome)
- Stem cell defects (aplastic anemia, myelofibrosis, Fanconi anemia, thalassemia major, sickle cell disease)
- Inborn errors of metabolism (Hurler syndrome, Hunter syndrome, adrenoleukodystrophy)
- Autoimmune disease (HLH, severe SLE)

DONOR SELECTION

- Optimal major histocompatibility antigen (HLA) matching of the donor to the recipient minimizes the risks of rejection and GVHD.
- HLA matching is important at the A, B, C, and DR loci (8/8 match is recommended in most cases).

- Additional HLA matching at the DQ and DP loci (12/12) may be important in some cases.
- For nonmalignant disease, donor preference is syngeneic > matched familial > unrelated.
- Matched unrelated donor: Over 18 million potential donors registered worldwide. Disadvantages include long search time (2–3 months), lower chance of finding an 8/8 match for minorities, increased risk of graft failure and GVHD, and slower immune reconstitution.
- Alternative donors include mismatched unrelated donor (match at $\geq 7/8$ HLA Ag), umbilical cord blood (match at $\geq 4/6$ HLA Ag), or haploidentical (parental) donor (4/8 matching requires ex vivo manipulation of the graft to deplete T cells in order to prevent fatal GVHD).
- Other donor characteristics to consider include age, gender, and CMV status. CMV reactivation risk is based on donor/recipient serologies:
 - D–/R–: very low risk
 - D+/R–: intermediate risk
 - R+: high risk; CMV+ donor is preferred.

CONDITIONING & TOXICITY

- 3 goals of conditioning (depending on disease):
 - Myeloablation (M): Clear space to allow stem cell engraftment.
 - Immunosuppression (I): Prevent rejection and GVHD.
 - Antineoplastic effect (N): Eradicate any remaining leukemia/tumor cells.
- Agents used during conditioning differ by their M/I/N effects and are used in combination to produce the desired outcome. Side effects of conditioning agents:
 - Total body irradiation (M/I/N): cognitive delay, poor growth, cataracts, abnormal dental development, pulmonary and cardiac dysfunction, pituitary dysfunction, infertility, 2nd malignancy
 - Busulfan (M/N): restrictive lung disease, seizures and possibly neurocognitive deficits, skin rash and hyperpigmentation, 2nd malignancy
 - Thiotepe (M/I/N): skin rash, hemorrhagic cystitis, 2nd malignancy
 - Melphalan (M/N): mucositis, cardiac dysfunction, 2nd malignancy

- Cyclophosphamide (I/N): cardiac dysfunction, SIADH, hemorrhagic cystitis, 2nd malignancy
- Etoposide (M/N): allergic reaction, hypotension, 2nd malignancy
- Fludarabine (I/N): cerebellar syndrome, peripheral neuropathy
- Carmustine (M/N): pulmonary toxicity, 2nd malignancy
- Alemtuzumab (Campath) (I): anaphylaxis, fever, hypotension, hives, viral and fungal infection
- Antithymocyte globulin (ATG) (I): anaphylaxis, fever, hypotension, hives, serum sickness, viral and fungal infection
- Nonmyeloablative or reduced toxicity regimens
 - Goal of reduced toxicity regimens is to allow partial donor stem cell engraftment, while limiting toxic effects of conditioning agents.
 - Indications include preexisting organ toxicity precluding full-dose chemotherapy; low performance status, often in the elderly; and primary DNA repair defects resulting in sensitivity to ionizing radiation and alkylating agents (Fanconi anemia, dyskeratosis congenita).
 - Uses lower doses of chemotherapy or lower dose of radiation.
 - Relies more heavily on the GVL effect of alloreactive donor T cells to control or eradicate any remaining neoplastic disease.

ONGOING CARE

COMPLICATIONS

Treatment-related mortality (TRM) has been declining over time (40% in 1987–1995 to 15% in 2003–2006) and is attributable to the following complications:

- Infection
 - Correlates with timing of immunologic defect (early or <100 days vs. late or >100 days from transplant)
 - Bacterial
 - Early bacterial infections are due to neutropenia, mucositis, or central line (Staphylococcus spp, gram-negative rods, Clostridium difficile, VRE, atypicals). Later, prolonged adaptive immunity defect and chronic GVHD are risks for mycobacteria

- and encapsulated bacteria.
 - Treat neutropenic fever empirically with broad-spectrum antibiotics.
 - Role of prophylactic antibiotics is under investigation.
- Viral
 - Early viral infections are due to lymphopenia, T-cell depletion, cord blood source, and previous viral exposures. Common infections include RSV, rhinovirus, adenovirus, influenza, and herpes virus reactivation (HSV, CMV, HHV-6). Persistent defect in adaptive immunity contributes to later infections such as CMV, VZV, and EBV/PTLD.
 - Acyclovir prophylaxis to prevent HSV reactivation
 - At detection of CMV viremia, rule out CMV retinitis with fundoscopic exam and begin preemptive therapy for CMV viremia with foscarnet or ganciclovir. For CMV organ involvement, consider Cytogam, IVIG, or intravitreal foscarnet for CMV retinitis. Continue maintenance therapy with ganciclovir or valganciclovir once viremia is cleared.
- Fungal
 - Combined innate and adaptive immunity defects (early) and persistent T-cell dysfunction (late) confer risk for Candida, Aspergillus, Pneumocystis, and other fungal infection (Fusarium, Zygomycetes/Mucor, Cryptococcus, Histoplasma, Coccidioides).
 - Prophylaxis: Fungal prophylaxis is with fluconazole (yeast coverage) or caspofungin; Pneumocystis prophylaxis is with cotrimoxazole before conditioning and after engraftment.
 - Treatment with voriconazole empirically for sustained fever without source (strong mold/Aspergillus coverage)
 - Decrease calcineurin inhibitor/sirolimus dose when starting voriconazole due to inhibition of cytochrome P450 metabolism.
 - Document infection (BAL) whenever possible.
- Mucositis
 - Grades 1–4 based on WHO classification (mild to severe).
 - Prevention: Reduced intensity protocols, glutamine, palifermin;

- consider holding posttransplant methotrexate if severe mucositis
 - Treatment: IV pain control, TPN, suction
- Veno-occlusive disease (VOD)/sinusoidal obstruction syndrome (SOS)
 - Due to hepatic accumulation of toxic metabolites leading to reduced hepatic venous outflow and postsinusoidal intrahepatic portal hypertension
 - Overall risk of VOD is 10–25%. Risk factors include mismatched or unrelated donor, previous hepatic tumor involvement or abdominal RT, pretransplant elevation of AST, and medications such as busulfan.
 - Diagnosis
 - Modified Seattle criteria: Any 2 of the following present by day +20: jaundice (bilirubin >2 mg/dL); painful hepatomegaly; or ascites ± weight gain of >2% from baseline
 - Baltimore criteria: bilirubin >2 mg/dL before day +21 and any 2 of the following: hepatomegaly, ascites, or weight gain (>5% from baseline)
 - Reversal of portal venous flow on ultrasound (US) is characteristic but not part of diagnostic criteria.
 - Prophylaxis may include ursodiol, N-acetylcysteine, or defibrotide (under investigation)
 - Treatment
 - Defibrotide: Porcine intestinal mucosal oligonucleotide. Anticoagulant with effects on endothelial cells, platelets, and fibrinolysis
 - Supportive care: restriction of sodium and fluid intake; diuresis to keep fluid balance even (spironolactone if able to take PO)
 - Complications of VOD include renal insufficiency, altered mental status, cardiac failure, and bleeding.
- Thrombotic microangiopathy
 - Diagnosis: RBC fragmentation, thrombocytopenia with increased need for frequent platelet transfusions, elevated LDH, concurrent renal and/or neurologic dysfunction
 - Calcineurin GVHD prophylaxis is a risk factor (CSA > tacrolimus). Combination with sirolimus triples the risk from

4.2% to 10.8%.

- Treatment: Discontinue calcineurin inhibitors; supportive care. Limited data for plasmapheresis, eculizumab (anticomplement C5), infliximab, and defibrotide.
- Engraftment syndrome
 - Cytokine-mediated inflammation due to increasing neutrophil activity
 - Usually occurs by day +28 (earlier for autos, later for cord blood transplants)
 - Characterized by rash, fever, and pulmonary edema at the time of engraftment or before neutrophil recovery
 - Treatment: rule out infection, then methylprednisolone for 3–7 days.
- Interstitial pneumonitis
 - Complication of TBI, chemotherapy (busulfan, Cytosan), or infection (fungal, CMV). Idiopathic pneumonia syndrome (IPS) if no etiology is found.
 - Diagnosis:
 - Cough, dyspnea, hypoxemia, fever
 - CXR/CT: diffuse versus focal consolidations, nodules or cavitary lesions suggestive of fungus
 - BAL: sensitive for CMV, RSV, PCP, other respiratory viruses. Less sensitive for fungus.
 - Treatment: early empiric broad-spectrum antibiotics and antifungals, respiratory support. Consider corticosteroids or TNF blockade for IPS.
- GVHD
 - See [GVHD](#) section

Immune Reconstitution

- Innate immunity recovers within 2–4 weeks posttransplant and includes monocytes, followed by granulocytes and NK cells.
- Adaptive immunity recovers over months to years, with peripheral expansion of donor memory T cells (1st wave) followed by thymic development of donor stem cells (2nd wave). Measurements of adaptive immune reconstitution include ALC, donor chimerism, lymphocyte phenotyping, T-cell function (proliferation to mitogen and

antigen), B-cell function (serum IgA/IgM and isohemagglutinin titers), and vaccine titers before and after revaccination.

- Revaccination: Effects of conditioning require revaccination with killed vaccines when adaptive immunity has recovered (approximately 1 year posttransplant). If titers demonstrate an immunologic response, live-attenuated vaccines are administered after 2 years.

OUTCOMES

- Overall: 10–20% transplant-related mortality from rejection (<1–8%); toxicity (including infection, 5–20% mortality); and GVHD (5–15% mortality). Additional risk of relapse ranges from 15 to 40%. Risks are modified by several factors:
 - Rejection risks: disease, donor match, cell dose
 - Toxicity risks: infectious risks, conditioning, performance status/organ function.
 - GVHD risks: HLA match, number of donor T cells infused, GVHD prophylaxis.
 - Relapse risks: disease, disease status, conditioning regimen, donor type

LONG-TERM EFFECTS

- Risk is based on doses of chemotherapy and/or TBI received and presence/severity of GVHD.
- Incidence at 10 years (and etiologies):
 - Pulmonary: 20% (TBI, busulfan, GVHD/bronchiolitis obliterans)
 - Ophthalmologic: 44% (TBI, steroids, GVHD)
 - Hypothyroidism: 36% (TBI, busulfan)
 - Osteoarticular: 29% (steroids, GVHD)
 - Cardiac: 11% (TBI, Cytosan, prior anthracyclines)
 - Hepatic: 16% (iron overload, GVHD)
 - Dental: 15% (TBI, GVHD)
 - Secondary malignancy: 5–10% (TBI, alkylators, VP16, immunodeficiency)
 - Infertility: >90% (TBI, alkylators)
 - Other effects include GH deficiency, hearing loss, hypogonadism, chronic renal insufficiency, neurocognitive defects.

- Long-term follow-up should include evaluations of disease physical exam, immune status, cardiopulmonary function, endocrine function, hepatic function renal function, ophthalmologic exam, audiology, and neurocognitive evaluation.
- Immunization strategy posttransplant

FAQ

- Q: Should friends and family of a patient needing a transplant be tested as a potential match?

- A: If family contacts are willing to donate for an unrelated patient in need of a stem cell transplant, they should join the National Marrow Donor Program (NMDP) registry. However, extended family members are very unlikely to be a match for a related patient.
- Q: Can transplant recipients meet their donors?
- A: The NMDP has guidelines for donor/recipient contact. If both parties agree, contact is allowed 1–2 years after the transplant.

BOTULISM AND INFANT BOTULISM

Jessica M. Khouri • Stephen S. Arnon

BASICS

DESCRIPTION

- An acute illness caused by neurotoxins produced by *Clostridium botulinum* or related neurotoxic species, which results in cranial nerve palsies and a symmetric, descending, flaccid paralysis
- The neurotoxin may be elaborated either in the large intestine of individuals temporarily colonized with the bacterium, or ingested, or absorbed from infected wounds.
- There are 3 main forms of the disease:
 - IB is the intestinal toxemia form in which swallowed spores germinate and colonize the infant's colon and elaborate toxin in situ.
 - Foodborne botulism in children and adults occurs when preformed toxin is ingested with improperly prepared or stored foods.
 - Wound botulism occurs when spores of the bacterium contaminate the wound, germinate, and produce toxin that is then absorbed.

EPIDEMIOLOGY

- Infant botulism (IB) is the most common form of human botulism in the United States.
- IB occurs in the 1st year of life, with ~90% of cases reported in the first 6 months of life.
- IB affects infants of all racial backgrounds and socioeconomic groups.
- Male to female ratio is 1:1.
- Toxin types A and B represent 95.7% of cases in United States (1976–2010), with dual toxin types (e.g., Ba, Bf) and more rare type E and type F comprising the remaining 4.3%.
- IB has been recognized in all 50 states, with a greater proportion of toxin type B cases east of the Mississippi River and toxin type A cases west of the Mississippi.
- Recognized on 5 of the 6 inhabited continents, Africa being the exception.

- Often, a history of a recent change in feeding practice is found.
- Honey is an identified food reservoir of *C. botulinum* spores. Honey consumption in U.S. IB patients from 1976 to 2010 was approximately 5.4%.
- For the majority of IB cases, spore acquisition likely occurs from the natural environment, that is, infants inhale and then swallow spores attached to airborne microscopic dust particles. Nearby soil disruption may play a role.
- Breastfed infants who acquire IB tend to be older at onset than are formula-fed infants.
- Foodborne cases are usually associated with home-processed, low acid foods—especially vegetables, fruits, and condiments. Restaurant-associated outbreaks have occurred. Recent outbreaks in U.S. prisons have been associated with fermented alcoholic beverage commonly referred to as pruno.
- Wound botulism has been associated with “black tar” heroin injection drug use and traumatic injuries in teenagers.

Incidence

- U.S. IB incidence: 2.2 cases per 100,000 live births (1976–2010). The states with the highest incidence in descending order include Delaware, Hawaii, Utah, Pennsylvania, and California.
- Approximately 80–130 IB cases annually in United States
- Since the disease was first recognized over 35 years ago, more than 3,700 cases of IB have been reported worldwide.
- Foodborne cases occur sporadically yet may result from a common exposure.
- Wound botulism is very rare.

RISK FACTORS

- Infants who have <1 bowel movement per day may be at increased risk of developing IB.
- Honey is an identified, avoidable food source of *C. botulinum* spores.
- Ingestion of improperly canned or preserved low-acid foods may result in foodborne botulism.

GENERAL PREVENTION

- Do not feed honey or raw honey-containing products to infants.
- Botulinum toxin is heat-labile; 5 minutes of boiling will destroy the toxin.
- Spores are heat-resistant.
- Proper food preservation, storage, and preparation will prevent foodborne botulism.

PATHOPHYSIOLOGY

- Neurotoxin is endocytosed at peripheral cholinergic nerve endings; it blocks release of acetylcholine at the neuromuscular junction.
- Cranial nerves are usually affected first and most severely, leading to ptosis, ophthalmoplegia, decreased facial expression, difficulty swallowing, and loss of airway-protective reflexes. Respiratory failure may ensue.
- Sensation and sensorium remain intact.
- Recovery occurs through regeneration of motor neuron axon terminals and the formation of new motor end plates.
- Infants are particularly prone to temporary colonic colonization by *C. botulinum*. When foods other than breast milk are introduced to breastfed infants, perturbation of the intestinal flora may predispose to illness.

ETIOLOGY

C. botulinum, the etiologic agent, is a gram-positive, spore-forming, obligate anaerobic bacterium that is found in dust, soil, and marine sediments worldwide. Rarely, neurotoxigenic *Clostridium butyricum* and *Clostridium baratii* may cause disease due to toxin type E and type F, respectively.

DIAGNOSIS

HISTORY

- IB
- Symptoms include constipation, poor feeding/poor latch, diminished facial expression, droopy eyelids, difficulty swallowing, and generalized weakness.

- Fever is typically absent (barring concomitant infections).
- Infants may appear lethargic (from ptosis and decreased facial expression).
- Occasionally, rapid progression of symptoms may result in respiratory arrest or an apparent life-threatening event (ALTE).
- Foodborne botulism
 - ~50% of patients report emesis.
 - There may initially be complaints of diarrhea followed by constipation.
 - The incubation period from ingestion to the onset of symptoms is usually 18–36 hours (range, a few hours to several days).
 - Patients complain of weakness and dry mouth.
 - Visual complaints include blurry vision, loss of accommodation, and diplopia.
 - Patients may complain of difficulty swallowing or slurred speech.
 - Patients may have urinary retention.
 - Occasionally, progression may be quite rapid, and the abrupt onset of lethargy and weakness may suggest bacterial sepsis or meningitis.
- Wound botulism
 - Often history of IV drug use
 - Incubation period ranges from 4 to 14 days.
 - Fever may be present from wound infection not botulism.
 - Patients often report constipation but rarely nausea or vomiting.
 - Patients may complain of purulent discharge from the wound.

PHYSICAL EXAM

- IB
 - Patients are typically afebrile and appear lethargic.
 - Cranial nerve findings include ptosis, diminished facial expression, weak cry, poor latch/suck, drooling/dysphagia, weak gag, and poor head control.
 - Pupils
 - Often midposition initially. May be normal to sluggishly reactive but fatigue with repetitive stimulation
 - In some cases, pupils appear fixed and dilated for a period.
 - Frog-leg positioning due to weakness of hip girdle musculature

- Generalized weakness and loss of motor milestones
- Flaccid, descending paralysis, and hyporeflexia
- The remainder of the physical examination is normal.
- Helpful physical examination findings:
 - In infants, early in the course of the disease, pupillary and corneal reflexes may fatigue easily (refer to physical examination tools under “For Physicians—Clinical Diagnosis” tab at www.infantbotulism.org)
- Older children and adults
 - May appear alert and are afebrile
 - Ptosis, extraocular palsies, and dilated, sluggishly reactive pupils are often the 1st signs of descending paralysis.
 - Dysphagia, dysarthria, and hypoglossal weakness indicate lower cranial nerve involvement.
 - Respiratory failure may rapidly ensue from upper airway obstruction resulting from loss of pharyngeal tone, loss of airway-protective reflexes, and respiratory muscle weakness.
 - The triad of bulbar palsies, clear sensorium, and absence of fever should prompt immediate consideration of botulism.
 - Signs of autonomic instability may include unexpected fluctuations in skin color, BP and heart rate, and urinary retention.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- For IB, stool or enema is submitted for diagnostic testing to a state health department or the Centers for Disease Control and Prevention (CDC). Diagnosis is established by identification of toxin by mouse neutralization assay and/or isolation of a toxigenic organism. Serum testing is not routinely performed. Clinicians should request specific instructions on specimen submission from their state health departments.
- In foodborne and wound botulism, tests for the presence of toxin or organisms can be conducted on patient samples (serum, gastric aspirates, feces, or wound exudate) or suspected foodstuffs.
- Anaerobic cultures of wound material may yield the organism.
- In infant and foodborne botulism, excretion of toxin and organisms in

feces may persist for weeks to months after symptom onset.

Imaging

EEG, MRI, and CT are nonspecific and usually normal in the absence of complications.

Diagnostic Procedures/Other

- Most tests for toxin and organism are done by state health departments or the CDC.
- The most common test performed is an assay for botulinum toxin in stool.
- Specimens must be shipped in sealed, break-proof, and leak-proof containers. Even minute amounts of toxin, if inhaled or ingested, can lead to disease.
- Suspect foods should be shipped refrigerated and in their original containers if possible.
- Electromyography (EMG) may demonstrate a characteristic pattern of brief, small, overly abundant motor unit action potentials (BSAPs). EMG results may be normal or inconclusive in botulism patients. Nerve conduction velocities are normal.

DIFFERENTIAL DIAGNOSIS

- Top 2 clinical mimics of IB are spinal muscular atrophy (SMA) type I and metabolic disorders.
- Infections
 - In infants, sepsis, meningitis and polio-like enteroviruses may present in a similar way.
 - In older children and adults, bacterial sepsis, meningitis, poliomyelitis, tick paralysis, and diphtheric polyneuritis
 - Postinfectious demyelinating processes may mimic botulism but generally have asymmetric findings.
 - Absence of fever and a clear sensorium make sepsis and meningitis less likely.
- Neurologic
 - Myasthenia gravis spares the pupillary constrictor response, which in botulism is either fatigable, sluggish, or absent.
 - In Werdnig-Hoffmann disease (SMA type I), extraocular and

sphincter muscles are spared.

- Metabolic/genetic
 - Certain metabolic or genetic conditions may closely mimic IB.
- Toxins: Drug ingestions may lead to weakness and lethargy.

TREATMENT

MEDICATION

- Prompt recognition of IB and early treatment with intravenous human botulism immune globulin (BabyBIG; BIG-IV) significantly shortens hospital stay, time in intensive care, and duration of respiratory and nutritional support. BabyBIG is available through the California Department of Public Health's Infant Botulism Treatment and Prevention Program (IBTPP).
- Treatment with BIG-IV should be promptly initiated based on clinical findings and not delayed for laboratory diagnostic studies.
- Antibiotics are not helpful in IB:
 - In suspected IB, avoid aminoglycoside antibiotics (e.g., gentamicin); an abrupt worsening of weakness and respiratory failure may result from potentiating effects at the neuromuscular junction.
- Equine-derived antitoxin is not recommended for the treatment of IB but has been used to treat type-F IB cases.
- Antibiotics are indicated only for documented complications such as pneumonia or urinary tract infections.
- Cathartics are not beneficial.
- Foodborne or wound botulism
 - Should be treated with the licensed, equine-derived heptavalent botulinum antitoxin (BAT), available from the CDC
 - Antitoxin should not be administered to asymptomatic individuals who have only eaten suspect foods.
- Wound botulism should be treated with IV penicillin G 250,000 U/kg/24 h or equivalent and BAT antitoxin.

ADDITIONAL TREATMENT

General Measures

- Patients with suspected botulism should be hospitalized and have continuous monitoring of heart rate, respiratory rate, and oxygenation, as well as frequent assessment of respiratory effort and airway-protective reflexes.
- The mainstay of therapy is meticulous supportive care. Particular attention should be paid to respiratory and nutritional needs.
- Endotracheal intubation is necessary for patients with respiratory failure or loss of airway-protective reflexes.
- Wounds should be explored and debrided and anaerobic cultures obtained.
- Cases of suspected toxin ingestion should be treated early with induced emesis and/or gastric lavage in an attempt to decrease toxin exposure.
- All suspect cases should be immediately reported to the state health department and the CDC.

INPATIENT CONSIDERATIONS

Initial Stabilization

Meticulous supportive care with particular emphasis on respiratory and nutritional needs is the most important consideration.

ONGOING CARE

PROGNOSIS

- IB has an estimated mortality rate of <1% in hospitalized patients. Complete recovery can be expected when the disease is recognized early and treated appropriately.
- The mortality rate of adult foodborne botulism is 20–25%. In patients <20 years old it is 10%.
- Patients with a shorter incubation period usually have more severe involvement and a worse prognosis, probably related to an increased amount of toxin ingested.
- If recognized early and treated aggressively, botulism has a favorable prognosis, and complete recovery can generally be expected. Fatigability may persist for up to 1 year.

COMPLICATIONS

- Fatal respiratory failure from paralysis of respiratory muscles is the most serious complication.
- Bulbar dysfunction in IB may lead to dehydration and starvation ketosis before presentation.
- Loss of airway-protective reflexes can lead to aspiration and pneumonia.
- Constipation and urinary retention may precede the onset of paralysis and may complicate later management. Cases of severe *Clostridium difficile* enterocolitis with hypovolemia, hypotension, and prolonged ICU stays have occurred in IB patients.
- Recurrent urinary tract infections and syndrome of inappropriate antidiuretic hormone secretion (SIADH) are rare complications of IB.

CODES

ICD10

- A05.1 Botulism food poisoning
- A48.51 Infant botulism
- A48.52 Wound botulism

FAQ

- Q: Can IB recur?
- A: True recurrence of IB has not been documented.
- Q: Should antitoxin be given to persons who have ingested food that they think might be contaminated with botulinum toxin (foodborne botulism)?
- A: Because the antitoxin carries a risk of serum sickness, it should be given only to persons exhibiting symptoms consistent with botulism.
- Q: Where is antitoxin obtained?
- A: For suspected IB cases human-derived antitoxin, BabyBIG (BIG-IV), may be obtained from the Infant Botulism Treatment and Prevention Program, California Department of Public Health, 24/7/365 Ph: 510-231-7600; www.infantbotulism.org.
- For non-IB patients, the licensed heptavalent (A–G) equine-derived antitoxin, BAT, may be obtained from the CDC, Atlanta, Georgia; 770-488-7100.
- Q: How is human-derived antitoxin, BabyBIG produced?
- A: BIG-IV; BabyBIG is produced from pooled human plasma from screened adult volunteers immunized against botulinum toxin for occupational protection.

BRAIN ABSCESS

Karen E. Jerardi • Samir S. Shah

BASICS

DESCRIPTION

- Suppurative infection involving the brain parenchyma
- May be a single or multiple lesions

EPIDEMIOLOGY

- Males more commonly affected (2:1 male-to-female predominance).
- Typical age of presentation is 4–7 years but varies according to predisposing factor.
- 85% of cases have a predisposing risk factor.

Incidence

~1,500–2,500 cases (adults and pediatric combined) occur per year with up to 25% being children.

RISK FACTORS

- Cyanotic congenital heart disease (tetralogy of Fallot is most common)
- Otorhinolaryngologic infections such as sinusitis, mastoiditis, and chronic otitis media
- Meningitis (especially in neonates)
- Penetrating head trauma
- Surgical manipulation of the brain (ventriculoperitoneal shunts, tumor removal)
- Congenital lesions of the head and neck
- Cystic fibrosis
- Dental infections
- Lung infections
- Patients who have traveled to endemic areas where neurocysticercosis (Latin America, parts of Africa, Asia, and the Indian subcontinent) is endemic
- Immunocompromised patients (congenital or acquired)

GENERAL PREVENTION

- During recreational activities, wearing helmets may prevent penetrating head trauma.
- Appropriate management of acute otitis media and acute sinusitis and timely recognition of treatment failure

PATHOPHYSIOLOGY

- Microorganisms enter the brain parenchyma by contiguous or hematogenous extension.
- Location of brain abscesses:
 - Cyanotic congenital heart disease patients tend to have abscesses within the middle meningeal artery distribution: frontal, parietal, and temporal lobes.
 - Frontal abscesses are commonly seen with sinus and dental infections.
 - Temporal, parietal, or cerebellar abscesses tend to occur with mastoiditis or otitis media.
 - Brain abscesses can occur anywhere in the brain parenchyma, regardless of a predisposing risk factor, secondary to hematogenous metastasis.

ETIOLOGY

- Bacteria are the most common causes.
- *Streptococcus milleri* group and *Staphylococcus* sp. are the most commonly cultured microorganisms.
- Neonates may develop brain abscesses as a complication of Gram-negative meningitis (*Proteus*, *Citrobacter*, *Enterobacter*, and *Cronobacter* species).
- Polymicrobial infections occur in 30–50% of cases.
- Anaerobic organisms are found with increasing incidence with improved laboratory and culture techniques. Common pathogens include *Bacteroides*, *Peptostreptococcus*, *Fusobacterium*, *Propionibacterium*, *Actinomyces*, *Veillonella*, and *Prevotella*.
- Neurocysticercosis is caused by the parasite, *Taenia solium*. Fungi and protozoa can cause brain abscess in immunocompromised patients.

DIAGNOSIS

HISTORY

The location of the brain abscess or abscesses will influence the clinical presentation.

- Classic triad of fever, headache, and focal neurologic findings occurs in <30% of cases.
- Fever, headache, and vomiting each occur in 60–70% of cases.
- Headache is the most common complaint.
- Vomiting and mental status changes can be the presenting chief complaints.
- Neonates will often have a history of meningitis before developing a brain abscess.
- Questions should focus on acute or chronic otolaryngologic infections.
- A history of cyanotic congenital heart disease should be obtained, as well as partially repaired cyanotic congenital heart disease.

PHYSICAL EXAM

- Neonates may present with a full fontanel, increasing head circumference, seizures, or vomiting.
- Older children may have signs of a focal neurologic deficit, hemiparesis, or even papilledema.
- Meningeal symptoms occur in 30% of patients.
- Ataxia may be found with cerebellar lesions.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Routine lab tests are not helpful and cannot rule out the diagnosis.
- <10% of blood cultures are positive.
- Peripheral WBC may be mildly elevated, but <10% will show band forms.
- ESR is a poor indicator of brain abscesses.
- Electrolytes may show low sodium, indicating syndrome of inappropriate secretion of antidiuretic hormone (SIADH).
- A lumbar puncture is contraindicated if any intracranial mass lesion is suspected, but if CSF is obtained:

- It may show a mild to moderate pleocytosis (20% of patients may have normal values).
- Opening pressure may be elevated.
- Glucose is decreased in 30% of patients.
- Protein is elevated in 70% of cases.
- CSF Gram stain and cultures are often negative.

Imaging

- CT with contrast and MRI scans are the studies of choice in diagnosing brain abscesses.
- Although CT can provide more rapid results, occult intracranial infections can be missed in up to 50% of cases.
- Cranial ultrasound may be useful in premature neonatal cases.

ALERT

- Not all patients with brain abscesses have fevers.
- Pitfalls
 - Failure to consider a brain abscess in a child with altered mental status, fevers, and meningismus or in a child with nonspecific symptoms but risk factors, such as cyanotic congenital heart disease
 - Failure to recognize symptoms not typically seen in sinusitis, such as vomiting

DIFFERENTIAL DIAGNOSIS

- Infectious
 - Meningitis
 - Encephalitis
 - Subdural empyema
 - Epidural abscess
- Vascular
 - Venous sinus thrombosis
 - Migraine
 - Cerebral infarct
 - Cerebral hemorrhage
- Miscellaneous
 - Primary or secondary tumor
 - Pseudotumor cerebri

- Hydrocephalus

TREATMENT

MEDICATION

- Broad-spectrum antibiotics that penetrate the CNS should be given at the time of diagnosis directed at most likely pathogens. The combination of a third-generation cephalosporin, vancomycin, and metronidazole provide good empiric coverage.
- Culture-directed antimicrobial therapy is recommended whenever possible. Typical antibiotic courses are 4–6 weeks.
- Consider neurosurgical and/or otolaryngology consultation.
- MRI or CT-guided stereotactic aspiration is encouraged to obtain cultures and identify the causative organism(s).
- Some patients are managed successfully with antibiotics alone, especially if there is a single, small (<2 cm) abscess.
- Antiparasitic medications (albendazole) with or without corticosteroids should be considered for treatment of neurocysticercosis.
- Antifungals should be considered for immunocompromised patients.
- Evaluation by cardiology, dental, otorhinolaryngology, and/or immunology may help identify predisposing factors.

INPATIENT CONSIDERATIONS

Initial Stabilization

- If a patient is manifesting signs and symptoms of increased intracranial pressure (Cushing triad: bradycardia, hypertension, and abnormal respirations) or if the patient is unable to protect his or her airway, endotracheal intubation is indicated. Hyperventilation and mannitol should be considered.
- Electrolyte abnormalities such as SIADH may occur. Frequent monitoring of electrolytes is warranted.
- Seizures and focal neurologic deficits can occur early in presentation. They typically resolve with drainage of the lesion. Careful and frequent neurologic exams should be part of the hospital care.

Admission Criteria

All patients with concern for brain abscess should be admitted for clinical monitoring, diagnostic evaluation, and treatment.

Discharge Criteria

Generally, patients may be discharged home once their symptoms have resolved and antibiotic therapy is complete or can be completed at home.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Follow-up with neurosurgical, rehabilitation, and neurology clinics is usually required.
- Repeat imaging prior to cessation of antibiotic therapy should be done to document resolution of the abscess.

COMPLICATIONS

- Long-term complications arise from the location, size, and number of intracranial abscesses.
- Multiple abscesses, coma on presentation, <2 years of age, and rupture of abscess into the ventricle carry a higher mortality rate.
- 30–40% of patients have some morbidity associated with brain abscess; seizures, hydrocephalus, focal neurologic deficits (motor and sensory dysfunction), and behavioral or personality changes are potential complications. Mortality rates have decreased because of advances in imaging to assist in rapid diagnosis and surgical management.

FAQ

- Q: Do all brain abscesses require surgery?
- A: No. Often times, brain abscesses will respond to intravenous antibiotics and will not require drainage. Close clinical and radiographic follow-up is imperative in these cases. Stereotactic aspiration of a brain abscess can be very helpful in identifying the microbiology of a brain abscess and help direct specific treatment.
- Q: What is the best imaging study to definitively diagnose a brain abscess?
- A: MRI

BRAIN INJURY, TRAUMATIC

Mark E. Halstead

BASICS

DESCRIPTION

Traumatic brain injury (TBI): damage to the brain from accidental or nonaccidental trauma

- Children >1 year: Glasgow Coma Scale (GCS) <14, amnesia >15 minutes for event, penetrating head injury (see [Appendix, Table 5](#))
- Children <1 year: any LOC, protracted emesis, suspected abuse (see [Appendix, Table 6](#))
- Mild brain injury : GCS >14
- Severe brain injury: usually initial GCS <9

EPIDEMIOLOGY

- Trauma, number 1 cause of death of children >1 year. Head injury most common contributor to morbidity and mortality
- Almost 500,000 emergency department visits each year for TBI for those aged 0–14 years. Males age 0–4 years highest rate of TBI emergency department visits
- 75% of TBIs each year are mild.
- <2 years old: Nonaccidental trauma is principal cause of TBI.
- >2 years old: Falls (~37%) are most common cause of trauma.
- For severe TBI, nonaccidental trauma remains principal cause in young children.
- Motor vehicle accidents in older children, although penetrating injuries becoming more common

PATHOPHYSIOLOGY

- Primary
 - Focally applied forces: lacerations, penetration injuries, skull fractures
 - Contusions, intracerebral hematomas uncommon. Epidurals, classic subdurals <10% in children

- Acceleration–deceleration/shearing forces: cervical spine injuries, diffuse axonal injury (DAI), nonaneurysmal subarachnoid hemorrhage, subdural hematoma (SDH) from shear forces
- Secondary
 - Extension of injury to viable tissue/entire brain
 - Dysautoregulation of cerebral blood flow, neuroexcitotoxicity, and inflammatory mediators. In severe TBI, CT or MRI signs of edema may progress over 3–5 days (see “[Treatment](#)”).
- Age-specific pathophysiology:
 - Infants/toddler
 - Shear forces on the brain due to acceleration/deceleration avulse axons from their cell bodies (DAI); often compounded by tearing and bleeding of dural veins
 - Unmyelinated infant brain absorbs rather than transfers impact. Immature, distensible skull renders brain less likely to contuse or herniated, but more likely to sustain diffuse secondary injuries, with swelling.
 - Subgaleal hematoma, cephalohematoma (below the periosteum), and caput succedaneum (confined to the superficial scalp) at birth do not predict brain injury.
 - More severe birth trauma can result in SDH.
 - Bilateral interhemispheric SDH suggests nonaccidental trauma.
 - Diffuse injuries secondary to shaken impact syndrome can lead to cerebral swelling with secondary infarction and/or decreased central respiratory control, leading to apnea, hypoxia, and cerebral edema.
 - Suspect nonaccidental trauma with growing skull fracture, if >1 cranial bone involved, or if other injuries are present.
 - Older children/adolescents
 - Mild TBI likely due to neuronal disruption, potassium efflux with release of glutamate. Increases demand of ATP and glucose.
 - Still more subject to DAI than adults due to incomplete myelination
 - Projectile injuries in adolescent population

DIAGNOSIS

HISTORY

- Eyewitness accounts are invaluable.
- Details of who was caring for the child
- Falls: Did loss of consciousness precede fall? Height of fall, surface of impact
- History of epilepsy, cardiac problems
- History of previous concussions (consider “second impact syndrome”) or trauma
- Intoxication (of child, caregiver, others in the environment)
- Prior physical abuse/neglect?
- Restrained motor vehicle passenger? Angle of impact
- How did patient act or change over time? Unresponsive? Confused? Headache? Visual changes? Vomiting? Seizure?
- Consider use of published concussion symptom checklists.

PHYSICAL EXAM

Rapid neurologic exam in trauma

- Can derive some of these by observation. Note presence of neuromuscular blockers/sedation:
 - Level of arousal: awake, lethargic, stuporous, unresponsive
 - Resting posture: spontaneous, restless, still normal, flexor, extensor
 - Respiration: in context of arousal and posture, hyperpnea, or Cheyne-Stokes respiration
 - Response to stimulation: voice, pain (of earlobe to avoid spinal withdrawal response); note localization, withdrawal, posturing.
 - Pupils: equal, anisocoria >1 mm, unequal/sluggish pupil, unequal/wide/fixed pupil
 - Extraocular movements: disconjugate gaze nonlocalizing with drugs/trauma, 3rd nerve palsy uncal herniation sign, 4th nerve palsy common in head injuries, 6th nerve palsy from trauma or increased ICP.
 - Brainstem reflexes: corneals (V & VII), oculoccephalic if patient unable to cooperate with eye exam and cervical spine cleared.

Avoid gag—raises ICP.

- Muscle reflexes/motor exam: Lateralizing signs may indicate contralateral hemispheric lesion, with ipsilateral dilated pupil may indicate uncal herniation.
- Sensory: brief for 4 limbs/spinal level if indicated
- This exam should be repeated often according to the patient's level of acuity. A more detailed exam tailored to degree of arousal can be done as the patient is stabilized.
- Mild TBI can be assessed with standard neurologic exam as outlined earlier. Balanced assessment and neurocognitive assessment (short-term memory, months of the year in reverse, digits in reverse) may be useful. Use of SCAT3 in sport concussion assessment may be beneficial on sideline or emergency department.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

In all patients with suspected TBI, consider:

- CBC (infants can have a large amount of intracranial blood loss)
- PT/PTT (to evaluate a possible bleeding disorder as a possible preoperative laboratory test)
- Electrolytes
- Toxin screen
- Laboratory studies likely not necessary in mild TBI unless laboratory abnormality suspected as contributor to TBI.

Imaging

- In mild TBI, imaging most likely not needed. High risk for lesion includes GCS <15 at 2 hours post injury, suspicion of open skull fracture, worsening headache, and irritability. Medium risk for lesion includes large, boggy hematoma, signs of basal skull fracture, and dangerous mechanism of injury.
- Unenhanced CT scan of the brain is the imaging study of choice for initial evaluation of a patient with suspected TBI.
- Abnormal CT: lesion density, midline shift, compression of cisterns, bone fragments
- MRI: useful for DAI (with a negative head CT) as well as showing

small lesions (e.g., punctate contusions)

- In suspected cervical spine injury where patient is unresponsive, CT scan initially with consideration for MRI of the spine to rule out noncontiguous unstable ligamentous injury.
- Long bone films if degree of injury is not consistent with history or history of fall from unclear height
- Consider EEG and lumbar puncture if a nontraumatic etiology for altered mental status is suspected, if CT normal.

DIFFERENTIAL DIAGNOSIS

Neurologic presentation varies in severity from a normal examination through coma similar to hypoxic-ischemic brain injuries (e.g., near-drowning), other causes of stupor/coma, seizure activity (postictal encephalopathy).

Distinction between simple concussion, DAI, and hypoxic-ischemic injury may be difficult at initial presentation, becoming clear as clinical picture/neuroimaging evolves.

TREATMENT

- Airway, breathing, circulation
- Cervical spine stabilization in unconscious patient with unclear mechanism of injury
- Prehospital stabilization: Avoid hypoxemia and hypotension (strong, possibly modifiable, independent predictors of outcome in TBI).

ADDITIONAL TREATMENT

General Measures

- For acute mild TBI, recommend physical rest and reducing cognitive stress while symptomatic.
- AAP guidelines set conditions for return to play depending on symptoms:
 - An AAP concussion statement outlines graduated return to activity if no return of symptoms and suggests (a) no same-day return; (b) and medical clearance needed before initiating return to activity progression.

- A rapid neurologic exam repeated over time is instrumental in directing the patient's care.
- For more severe trauma or in infants
- Secondary survey: external evidence of head injury/deformities, ecchymoses (periorbital-orbital roof fracture; mastoid-petrous temporal fracture), lacerations, penetrations. CSF leak nasal/otic
- Seizures: lorazepam 0.05–0.1 mg/kg IV at 2 mg/min or rectal Diastat 0.3–0.5 mg/kg if no IV access. Then load fosphenytoin 15–20 mg/kg IV. Important to treat to avoid increased ICP, neurotoxicity, hypoxia
- No evidence that seizure prophylaxis >1 week post trauma prevents late seizures
- No evidence that steroids improve outcome
- Hypothermia may be protective in severe TBI, no difference in long-term outcome.
- No evidence for prophylactic use of mannitol, although it is effective for control of increased ICP. Bolus doses 0.25 g/kg of body weight to 1 g/kg of body weight to goal ICP <20 mm Hg
- Hypertonic 3% saline IV for increased ICP as above under fluid resuscitation
- The postresuscitation GCS score should be recorded in all trauma patients.
- Involvement of neurosurgery with moderate GCS <13 injury, even if patient initially stable
- Survival for children with severe TBI is greater when treated in pediatric ICU.
- Decompressive craniectomy may be considered given the following conditions:
 - Diffuse cerebral swelling on cranial CT imaging
 - Within 48 hours of injury
 - No episodes of sustained ICP >40 mm Hg before surgery
 - GCS >3 at some point subsequent to injury
 - Secondary clinical deterioration
 - Evolving cerebral herniation syndrome

INPATIENT CONSIDERATIONS

Initial Stabilization

- Cervical spine stabilization and clearance; in severe TBI, entire spine is stabilized:
 - If necessary, orotracheal intubation with rapid sequence induction; avoid hypotension.
 - Hyperventilation may induce regional cerebral ischemia in children, especially in first 24 hours.
 - Increased ICP managed by bed elevation of 30 degrees, hypertonic fluids, sedation
- Hemodynamic stabilization (normal high systolic BP ~135) predictor of better outcome in TBI (median systolic BP = 90 mm Hg + [2 × age in years])
 - Hemodynamic instability indicative of systemic hemorrhage (abdomen, long bone fractures). Pericardial tamponade (narrow pulse pressure). Neurogenic shock
 - Hypotension late sign. early: ↓HR, ↑capillary refill, ↓urine output
 - Fluid resuscitation: Consider hypertonic saline. Mounting evidence of improved outcomes especially with hemorrhagic shock and TBI (titrate continuous 3% saline infusion 0.1–1 mL/kg/h).
 - Fluid bolus may worsen intracranial hypertension (ICP).
 - Consider monitoring ICP to maintain <20 mm Hg for abnormal admission CT scan, and GCS 3–8 after CPR, or normal CT and GCS 3–8, and posturing, or hypotension, or if serial neurologic exams precluded by sedation.

ONGOING CARE

PROGNOSIS

- Majority of mild TBI patients recovery without significant sequelae
- Presence of both hypoxemia and hypotension on arrival to ER bode poorly.
- 24-hour GCS better predictor of outcome than postresuscitation; PRISM score also helpful
- GCS <3 poor prognosis unless secondary to epidural hematoma; rapid evacuation can minimize permanent deficits.
- Diffuse white matter, subcortical gray, or brainstem lesions on MRI

portend long periods of coma and poorer outcome.

- Somatosensory-evoked potentials (VEPS or BAEPs) are less sensitive but have high specificity in predicting neurologic outcome.
- Degree of injury on head CT can be predictive.
- Patients who have sustained moderate to severe head injury (GCS = 13) often have academic difficulties, memory abnormalities, and disinhibition.
- Monitoring for cognitive difficulties, hyperactivity, seizures, hydrocephalus, movement disorders, paralysis, visual/hearing disturbance, headache; psychologists, neurologists, neurosurgeons, ophthalmologists, audiologists, and physical therapists may be helpful.
- Refer any patient with known skull fracture who manifests a new swelling in area of old fracture to neurosurgery for 3-D CT imaging of the head.
- ~10% of patients with severe head injury will develop epilepsy.

BRAIN TUMOR

Jane E. Minturn • Michael J. Fisher

BASICS

DESCRIPTION

A primary neoplasm arising in the CNS

EPIDEMIOLOGY

- Most common solid neoplasm of childhood (2nd to leukemia in overall incidence)
- Slight male predominance
- Majority arise infratentorially (within cerebellum or brainstem) in children 1–11 years of age.
- Majority arise supratentorially in children <1 year of age.

Incidence

- Incidence rising (>3,000 new cases/year)
- 4.5 cases/100,000 children/year
- Peak incidence in children ≤ 7 years of age

RISK FACTORS

Genetics

- Not a heritable condition
- Primary CNS tumors are associated with several familial syndromes:
 - Neurofibromatosis with optic pathway gliomas (NF1) and meningiomas (NF2)
 - Tuberous sclerosis with gliomas and rarely ependymomas
 - Li-Fraumeni syndrome with astrocytomas
 - Von Hippel-Lindau with cerebellar hemangioblastoma
 - Turcot syndrome with primitive neuroectodermal tumor

PATHOPHYSIOLOGY

The majority of tumors are classified based on their histology. The most common are the following:

- Glioma

- Arises from glial cells (e.g., astrocytes most common)
- >50% of childhood CNS tumors
- Ranges from low-grade (often in the cerebellum or optic pathway) to high-grade (grade III–IV; in the cerebrum or brainstem)
- Locally recurrent and invasive when high-grade
- Primitive neuroectodermal tumor/medulloblastoma
 - Malignant embryonal tumor arising from unknown cell type
 - Comprises ~20% of childhood CNS tumors
 - Most common malignant brain tumor in children
 - Majority arise in the midline of the cerebellum (referred to as medulloblastoma).
 - Predisposition for leptomeningeal dissemination
- Ependymoma
 - Arises from ependymal cells that line the ventricular system
 - 8–10% of childhood CNS tumors
 - Most commonly occurs in the 4th ventricle; may arise in the spinal cord
 - Locally recurrent and invasive; spinal metastases rare at initial diagnosis
- Germ cell tumor
 - Derived from totipotent germ cells
 - 3–5% of childhood CNS tumors
 - Majority are located in the pineal or suprasellar region.
- Atypical teratoid/rhabdoid tumor
 - Rare embryonal tumor arising from unknown cell type; often misdiagnosed as primitive neuroectodermal tumor
 - <3% of childhood CNS tumors
 - Majority arise in children <5 years of age.
 - Propensity to arise in the posterior fossa with frequent leptomeningeal dissemination; reported in association with malignant rhabdoid tumors of the kidney
- Craniopharyngioma: 6–9% of childhood CNS tumors
- Choroid plexus tumors (papilloma and carcinoma)
- Ganglioglioma
- Meningioma and hemangioblastoma, rare in children

ETIOLOGY

- No specific causative agents are known, but there is an association with radiation, chemical exposure, other malignancies, familial/heritable diseases, immunosuppression/immunodeficiency (CNS lymphoma).
- Molecular markers and variants of individual tumor types are being identified.

DIAGNOSIS

Tumor location dictates symptoms and signs.

HISTORY

- Headache and vomiting (particularly in the morning), irritability, and lethargy are associated with increased intracranial pressure.
- Difficulty swallowing, slurred speech, and diplopia may indicate brainstem tumor.
- Visual field deficits (bumps into things) could indicate optic pathway lesion.
- Focal weakness hints at pyramidal tract lesion.
- Ataxia may be a sign of cerebellar lesion.
- Changes in behavior or school performance, new-onset seizures, and weakness could be signs of supratentorial lesion.
- Polyuria/polydipsia may indicate hypothalamic/pituitary lesion.
- Failure to thrive, emaciation, euphoria, and increased appetite in an infant may indicate hypothalamic lesion (diencephalic syndrome).
- Back pain, extremity weakness, and bowel/bladder dysfunction could signify spinal cord metastases (often seen with primitive neuroectodermal tumor/medulloblastoma and germ cell tumors).

PHYSICAL EXAM

- Papilledema, impaired upgaze and/or lateral gaze, macrocephaly (infants), and bulging fontanelle are signs of increased intracranial pressure.
- Focal deficit on neurologic exam helps localize the mass lesion:
 - Isolated cranial nerve VI and VII palsies may indicate brainstem tumor.

- Ataxia and dysmetria could indicate cerebellar mass.
- Decreased visual acuity, visual field deficit, absent pupillary light response, and strabismus may all be signs of optic pathway tumor.
- Changes in cognitive function, mood, and affect could indicate supratentorial lesion.
- Impaired upgaze, convergence nystagmus, and pupils responding to accommodation but poorly to light are signs of pineal lesion (Parinaud or dorsal midbrain syndrome).
- Signs of neurocutaneous disease (e.g., café au lait spots, Lisch nodules) may indicate a syndrome such as neurofibromatosis type 1.

DIAGNOSTIC TESTS & INTERPRETATION

Imaging

- MRI with and without gadolinium enhancement is the “gold standard” for identification, localization, and characterization of tumors.
- CT can be used as an initial study, but if negative and a high index of suspicion, follow with MRI. Useful to evaluate for hydrocephalus and hemorrhage

Diagnostic Procedures/Other

Staging of tumor

- Postoperative head MRI within 24–48 hours to determine residual disease before postoperative inflammatory changes are prominent
- Spine MRI and CSF cytology required for neuraxis staging of tumors with high risk of leptomeningeal dissemination
- Elevated α -fetoprotein and quantitative β -human chorionic gonadotropin in CSF and serum are markers for germ cell tumors.

DIFFERENTIAL DIAGNOSIS

- Infection: cerebral abscess
- Tumors: metastatic tumor to brain, uncommon with childhood cancers
- Trauma: hemorrhage unlikely to be confused with tumor
- Congenital
 - Arteriovenous malformation
 - Hamartoma
 - Dysplastic brain
- Psychosocial: Some patients with nausea, vomiting, or behavior

changes are first diagnosed with psychiatric disorders, GI disorders, failure to thrive, or anorexia nervosa prior to discovery of a brain tumor.

ALERT

New onset of psychoses should prompt imaging to rule out tumor.

TREATMENT

SURGERY/OTHER PROCEDURES

- Both for histology and to attempt maximal tumor debulking; should be performed by experienced pediatric neurosurgeon
- Rarely indicated in intrinsic pontine (brainstem) glioma; although biopsy for molecular profiling increasingly in use
- Ventriculoperitoneal shunt or endoscopic 3rd ventriculostomy when needed for obstructive hydrocephalus (risk of peritoneal seeding minimal)

ALERT

Patient should be referred to a pediatric brain tumor/oncology center at diagnosis (preoperatively).

Radiotherapy

- Volume and dose vary depending on histology.
- Radiation therapy to the tumor bed is used for most patients with brain tumors.
- Medulloblastoma/primitive neuroectodermal tumor patients need craniospinal radiation therapy. The one exception is infants and young children (<3 years of age) in whom cognitive deficits from radiation therapy are devastating.
- Duration of radiation therapy: usually 6 weeks
- Newer approaches to limit exposure of normal brain include intensity-modulated and proton radiotherapy.

MEDICATION

- Dexamethasone to control increased intracranial pressure (0.5 mg/kg/24 h IV/PO divided q6h)

- Chemotherapy
 - Drugs are most often used in combination:
 - Carboplatin, vincristine, or 6-thioguanine, procarbazine, CCNU, vincristine for low-grade glioma
 - Cisplatin, CCNU, vincristine, etoposide, and cyclophosphamide are active agents for primitive neuroectodermal tumor/medulloblastoma.
 - Temozolomide for high-grade glioma
 - New protocols currently being evaluated:
 - High-dose chemotherapy with autologous stem cell rescue for high-risk primitive neuroectodermal tumor/medulloblastoma
 - Targeted therapies, angiogenesis inhibitors
 - Duration of chemotherapy: 6 months to 2 years

ALERT

Possible conflict with other treatments: Chemotherapy can alter anticonvulsant levels.

ONGOING CARE

- Neurologic deficits can take months to improve or stabilize with permanent deficit.
- Any worsening or relapse of symptoms must be evaluated for tumor recurrence.
- MRI every 3 months the 1st year, every 6 months for the next 2 years, and annually thereafter. Benefit of routine surveillance imaging is controversial.

PROGNOSIS

- Dependent on histology of tumor, location, and extent of initial resection
- Glioma
 - Low-grade: $\geq 90\%$ 5-year progression-free survival (PFS) following gross total resection; 45–65% for subtotal resection
 - High-grade: median survival 8–31 months; depends on grade and extent of resection

- Intrinsic pontine: median overall survival of 9–13 months from diagnosis
- Medulloblastoma
 - 79–83% PFS at 5 years if localized, gross total resection achieved, and >3 years old at diagnosis
 - <50% PFS if disseminated
- Ependymoma
 - 50–70% survival at 5 years with total resection
 - <30% survival with subtotal resection
- Infants overall have a worse prognosis, possibly due to the limitations of therapy and/or the aggressiveness of the tumor.

ALERT

Even benign tumors may be life threatening if their location precludes resection.

COMPLICATIONS

- Secondary to disease
 - Increased intracranial pressure
 - Obstruction of CSF flow
 - Requires immediate neurosurgical evaluation
- Secondary to radiotherapy
 - Neurocognitive sequelae (age- and dose-related)
 - Endocrinopathy (growth hormone deficiency, hypothyroidism, gonadal dysfunction)
 - Risk of second malignancies (meningioma, glioma, sarcoma)
 - Increased risk of stroke
- Secondary to chemotherapy
 - Risks associated with bone marrow suppression (infection, bleeding, anemia)
 - Hearing loss
 - Risk of secondary leukemia

CODES

ICD10

- D49.6 Neoplasm of unspecified behavior of brain
- C71.9 Malignant neoplasm of brain, unspecified
- D33.2 Benign neoplasm of brain, unspecified

FAQ

- Q: Are my other children at risk for getting a brain tumor?
- A: No (except in rare cases of certain familial syndromes).
- Q: Did something I do caused this?
- A: No. In addition, the claims made about high-power lines and cellular phones causing brain tumors or cancer are unproven.

BRANCHIAL CLEFT MALFORMATIONS

Anita Bhandari • Raezelle Zinman

BASICS

DESCRIPTION

- Phylogenetically, the branchial apparatus represents the “gills” seen in fish and amphibians.
- The fetal branchial apparatus is a foregut derivative and develops in the 2nd fetal week.
- Five paired pharyngeal arches are separated by four endodermal pouches internally and four ectodermal clefts externally.
- Overgrowth of the second through fourth cleft creates the cervical sinus and occurs during weeks 4 and 5.
- Persistence of the cervical sinus produces a spectrum of cysts, sinus tracts, and fistulae.
- Classification
 - First branchial cleft anomalies
 - Site: anywhere from external auditory canal to angle of mandible, usually superior to or within parotid
 - Fistula tract: external auditory canal
 - Second branchial cleft anomalies
 - Site: ventral to anterior border of sternocleidomastoid muscle, lateral to carotid sheath, and dorsal to submandibular gland
 - Fistula tract: palatine tonsil
 - Third branchial cleft anomalies
 - Site: posterior triangle in middle to lower left side of the neck near level of upper thyroid lobe
 - Fistula: upper lateral piriform sinus wall to lower lateral neck posterior to sternocleidomastoid muscle
 - Fourth branchial cleft anomalies
 - Site: close association to thyroid gland associated with clinical thyroiditis if cyst infected
 - Fistula: apex of piriform sinus to base of neck anterior to

sternocleidomastoid muscle

EPIDEMIOLOGY

- Overwhelming majority of cysts in newborns and infants are developmental, whereas in children and adults, they are inflammatory or neoplastic.
- Branchial cleft cysts are the most common congenital neck lesion. Although congenital, usually present in older children and adults.
- Branchial fistula and sinuses are common in children but cysts are more commonly seen in adults.
- Midline malformations are most often thyroglossal duct cysts or dermoids.
- Cysts occurring in the laterocervical region are usually branchial cleft malformations; the most common of these are derivatives of the second cleft, followed by those of the first cleft, of the fourth pouch and thymic cysts.
- Third and fourth branchial cleft anomalies are rare, with most presenting as sinus tracts rather than cysts.
- Suspect congenital anomaly in the clinical setting of recurrent infection.

RISK FACTORS

Genetics

Familial history of branchial defects occasionally noted

DIAGNOSIS

HISTORY

- Present since birth
- Recurrent neck infections
- Intermittent discharge from neck
- Fever
- Tenderness

PHYSICAL EXAM

- Mass usually mobile

- Usually a single lesion
- Nonpulsatile
- Lesion usually nontender (unless actively infected)
- Assess for sites of drainage:
 - At the anterior or posterior border of the sternocleidomastoid muscle
 - In the posterior pharynx at the tonsillar fossa or piriform sinus

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Complete blood count with differential: Increased white blood cell count with left shift seen with infection.
- Tuberculin test and interferon-gamma release assays to rule out mycobacterial infection, including atypical mycobacteria
- Microbiology: Oral cavity flora in neck abscess is suspicious for a branchial pouch anomaly.

Imaging

- Chest radiography to assess for hilar adenopathy, suggesting a systemic process (such as tuberculosis or malignancy)
- Lateral neck radiography to assess for airway compromise (not usually seen)
- Ultrasound to help differentiate solid masses from cystic masses
- Fistulogram to inject contrast into the fistula to delineate its course
- Computed tomography (CT) scan of neck for superior spatial delineation and definition of anatomic compartment of the lesion
- Magnetic resonance imaging (MRI) for more detailed soft tissue characterization and recognition of solid components within cystic masses
- CT scans and MRI may be used for preoperative planning in patients with recurrent neck masses or clinically complex cases

DIFFERENTIAL DIAGNOSIS

- Congenital
 - Anterior triangle of neck
 - Thymic cyst
 - Midline and anterior triangle of neck

- Ranula
 - Laryngocele
 - Sialocele
 - Thyroglossal cyst
 - Dermoid/teratomatous cyst
 - Bronchogenic cyst
- Posterior triangle of neck
 - Lymphangioma
 - Hemangioma
- Inflammatory
 - Adenitis
 - Granulomatous disease (sarcoidosis, tuberculosis)
 - Lymphoepithelial cysts (HIV)
 - Otorrhea
 - Parotiditis
 - Retropharyngeal abscess
 - Thyroiditis
- Tumors
 - Lymphoma
 - Rhabdomyosarcoma
 - Cystic schwannoma (anterior triangle of neck)
 - Pilomatrixoma

TREATMENT

MEDICATION

Antibiotics are indicated if the lesion is infected.

SURGERY/OTHER PROCEDURES

- Excision of the entire lesion is the standard approach.
- Novel endoscopic and marsupialization approaches have been reported.
- Surgery should be delayed if infection is present.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Postoperative follow-up as outpatient for wound inspection
- Observation for recurrence or reinfection

ALERT

- Lesion may recur if not completely excised.
- High incidence of reinfection if not properly treated.

PROGNOSIS

If lesion completely excised: excellent. Many patients require multiple procedures.

COMPLICATIONS

- Cysts, sinus tracts, and fistulas can become recurrently infected (especially with abscess formation).
- Surgery is more difficult if there has been previous infections or previous surgery.
- Damage to facial, hypoglossal, and glossopharyngeal nerves, internal jugular vein, or carotid artery can occur during surgical repair.
- Cyst, fistula, or sinus recurrence
- Thyroiditis
- Parotiditis (more common in first branchial arch malformation)

CODES

ICD10

- Q18.2 Other branchial cleft malformations
- Q18.0 Sinus, fistula and cyst of branchial cleft

FAQ

- Q: Can the cyst, fistula, or sinus recur?
- A: Only a 3% recurrence rate is seen if the lesion is completely excised. A higher rate of recurrence is seen in cases of incomplete excision or with previous surgeries.
- Q: Should the lesion be removed as soon as it is discovered?
- A: The lesion should not be removed if there is an active infection present; treat the infection first and then schedule elective surgery.
- Q: What is the likelihood that a pediatric neck mass is malignant?
- A: Most neck masses in childhood are either developmental or inflammatory but up to 15% may be neoplastic.

BREAST ABSCESS

Charles A. Pohl

BASICS

DESCRIPTION

- Breast abscess: infection of the breast bud or tissue associated with localized pus and inflammation
- Mastitis: infection of the breast tissue observed primarily during lactation

EPIDEMIOLOGY

- 5–11% of women with breastfeeding mastitis develop a breast abscess.
- Affects primarily infants (peak age 1–6 weeks) and adolescents
- Bilateral abscesses, seen among neonates, are rare.
- Male-to-female ratio is 1:2 in neonates.

RISK FACTORS

- In lactating teens, primiparity
- Gestational age >40 weeks
- Mastitis
- Obesity, black race, tobacco use

GENERAL PREVENTION

- Avoid breast manipulation (including piercing).
- In lactating teens, establish good breastfeeding techniques.
- Recognize and treat mastitis early.

PATHOPHYSIOLOGY

- Newborns
 - Trauma, breast hypertrophy from maternal estrogen, or compromised host defenses enable spread of bacteria that often colonize the nasopharynx and umbilicus.
 - The bacteria and/or its toxin, in turn, cause(s) subcutaneous destruction and loculated pus formation.
- Adolescents/adults: Trauma (e.g., sexual manipulation, nipple rings,

tight-fitting bras, incorrect latching during breastfeeding), contiguous spread of a local infection (e.g., mastitis, acne), or underlying structural abnormalities (e.g., mammary duct ectasia, epidermal cysts) cause breast tissue edema and destruction by bacteria and/or its toxin.

- When mastitis is associated with breastfeeding, the inflammation inhibits milk release. The stasis of milk, in turn, may allow for bacterial proliferation.

ETIOLOGY

- Newborn infection: *Staphylococcus aureus* (most common), group A or B *Streptococcus*, *Bacteroides* species, and gram-negative enteric bacteria, including *Escherichia coli*, *Pseudomonas aeruginosa*, *Proteus mirabilis*, *Salmonella* species
- Adolescent/adult infection: *S. aureus* (most common) with up to 19% being methicillin-resistant, *E. coli*, *P. aeruginosa*, *Mycobacterium tuberculosis*, *Neisseria gonorrhoeae*, and *Treponema pallidum* are infrequent pathogens.

DIAGNOSIS

HISTORY

- Ask about history of breast trauma or manipulation, concomitant illness or infections, and patient's immunologic status.
- Constitutional symptoms including irritability and lethargy usually are absent unless the infection involves deeper tissue or the bloodstream (1/3 of cases).
- Low-grade fever
- *Salmonella* infections generally present with GI symptoms.

PHYSICAL EXAM

- Firm, tender breast mass with overlying erythema and warmth. Fluctuant mass may be present.
- Regional adenopathy
- Purulent nipple discharge (rare)
- Necrotizing fasciitis is distinguished from breast abscess by pain out of proportion to the cutaneous signs, crepitus, or presence of straw-

colored bullae.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Gram stain and culture of nipple discharge, needle aspirate, and/or surgical incision and drainage help(s) guide therapeutic decisions if a fluctuant mass or discharge is present.
- Blood culture
 - Useful in neonates
 - Consider full sepsis workup if patient is febrile and toxic-appearing, or < 28 days old.
- CBC: Leukocytosis ($>15,000$ cells/mm³) is present in 1/2–2/3 of patients.
- Surveillance cultures of nasopharynx and umbilicus should be considered in neonates to rule out colonization with *S. aureus*.

Imaging

Ultrasound may be useful if fluctuant mass is suspected or if poor response to antimicrobial therapy.

Diagnostic Procedures/Other

If fluctuant, needle biopsy may be diagnostic and therapeutic.

DIFFERENTIAL DIAGNOSIS

- Physiologic conditions:
 - Breast engorgement (usually bilateral; absence of fever, erythema and tenderness)
 - Mastodynia (painful breast engorgement; associated with ovulatory cycles; cyclic pattern)
- Infectious: cellulitis including mastitis (absence of a loculated breast mass)
- Tumors (rare):
 - Fibroadenomas
 - Rhabdomyosarcoma
 - Non-Hodgkin lymphoma
 - Fibrocystic disease
 - Intraductal papilloma

- Cystosarcoma phyllodes
- Hemangioma
- Trauma:
 - Contusion (firm, tender, poorly defined mass)
 - Hematoma (sharply defined mass with ecchymosis)
 - Fat necrosis (firm, nontender, circumscribed, mobile mass)
- Miscellaneous: Mondor disease (thrombophlebitis of the subcutaneous veins in the breast)
 - Typically seen in adults
 - Presents with tenderness and pain
 - Associated with trauma
 - Spontaneously resolves
- Vascular malformation

ALERT

- Neonatal infections require prompt recognition, intervention, and identification of other involved sites to avoid widespread infection and poor outcome.
- Unrecognized fluctuant mass and its subsequent drainage will delay therapeutic response.
- Incidence of community-acquired methicillin-resistant *Staphylococcus aureus* (CA-MRSA) is increasing in many regions of the country.

TREATMENT

MEDICATION

- Neonatal infection (specific dosage interval based on degree of prematurity)
 - Parenteral β -lactamase-resistant antistaphylococcal antibiotics (e.g., nafcillin 75–100 mg/kg/24 h) or cefotaxime 100–200 mg/kg/24 h)
 - Aminoglycosides (e.g., gentamicin) should be included if the infant appears ill or if the Gram stain reveals gram-negative bacilli.
 - Consider vancomycin (40 mg/kg/24 h) if MRSA suspected in neonate older than 1 month of age.
- Adolescent infection

- Parenteral antistaphylococcal antibiotics (e.g., nafcillin 50–100 mg/kg/24 h; maximum 12 g/24 h)
- Consider amoxicillin-clavulanic acid orally (45 mg/kg/24 h or 875 mg b.i.d.) or clindamycin (450–1,800 mg/24 h orally with max dose 1.8 g/24 h; 1,200–1,800 mg/24 h parenterally with max dose 4.8 g/24 h) in patients with penicillin allergies and those who are well-appearing and without systemic symptoms.
- Consider adding aminoglycosides in situations as described earlier.
- Consider vancomycin, clindamycin, or trimethoprim-sulfamethoxazole if MRSA suspected.
- Duration
 - Usually for 10–14 days
 - Length of parenteral treatment is based on isolate and the clinical response. Oral agents may be used after a few days if a good clinical response occurs.

ADDITIONAL TREATMENT

General Measures

- Warm compresses
- Nonsteroidal anti-inflammatory agents (NSAIDs) help control the inflammation and pain in older children.
- Continuation of breast milk expression helps prevent engorgement and further milk stasis.

ISSUES FOR REFERRAL

Consider referral to an infectious disease specialist if recurrent.

SURGERY/OTHER PROCEDURES

- Incision and drainage if a fluctuant mass is present
- Surgical exploration is necessary if necrotizing fasciitis is suspected.

INPATIENT CONSIDERATIONS

Admission Criteria

- Ill appearance
- Neonates
- Inability to tolerate oral medications
- Concern for medication nonadherence

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Clinical improvement should be evident after 48 hours of parenteral antibiotics.

ALERT

Signs to watch for are the following:

- A poor or delayed clinical response to antibiotic therapy suggests a resistant organism, an unusual pathogen, or a different diagnosis.
- An evolving fluctuant mass warrants surgical intervention.
- Reaccumulation of fluctuant mass
- Toxic appearance, prolonged fever, purulent discharge, or progressive erythema postoperatively
- Crepitus associated with excessive pain and/or straw-colored bullae suggests necrotizing fasciitis.

PATIENT EDUCATION

- Continue breastfeeding.
- Establish good breastfeeding techniques.

PROGNOSIS

- Most children recover without any sequelae.
- Neonates are more likely to have bilateral abscesses (<5% cases).
- Neonates have higher morbidity and complications.

COMPLICATIONS

- Cellulitis (most common; 5–10%)
- Abscess rupture with disseminated infection (e.g., bacteremia, pneumonia)
- Septicemia
- Toxin syndromes (e.g., toxic shock syndrome)
- Necrotizing fasciitis
- Scar formation from mammary gland destruction (associated with a reduced breast size after puberty)
- Mammary duct fistula

CODES

ICD10

- N61 Inflammatory disorders of breast
- P39.0 Neonatal infective mastitis
- O91.219 Nonpurulent mastitis associated w pregnancy, unsp trimester

FAQ

- Q: How can you differentiate a breast abscess from mastitis?
- A: Although both illnesses involve signs of inflammation (i.e., warmth, erythema, swelling, tenderness), a breast abscess is distinguished from mastitis in that the former presents as a firm, well-defined mass (with or without fluctuant material).
- Q: Should a mother discontinue breastfeeding if she has a breast abscess?
- A: To avoid milk stasis, breastfeeding should be continued unless impeded by a surgical incision site or the overall clinical condition of the mother.

- Q: What is the role of homeopathic remedies (e.g., belladonna, Phytolacca) in the treatment of mastitis and breast abscess?
- A: Currently, there is insufficient scientific evidence to support their routine use.
- Q: Are anaerobic organisms common pathogens for breast abscesses?
- A: No. Although anaerobic pathogens are isolated in up to 40% of infections, their role is controversial, and therapy directed at them is unnecessary.

BREAST MILK AND BREASTFEEDING

JAUNDICE

Jennifer A. F. Tender • Sahira Long

BASICS

DESCRIPTION

The 3 major categories of unconjugated hyperbilirubinemia associated with breastfeeding:

- Physiologic jaundice: occurs between 1 and 7 days of life and peaks at 3–5 days.
- Breastfeeding jaundice (BFJ): exaggerated physiologic jaundice associated with inadequate milk intake.
- Breast milk jaundice (BMJ): occurs between 1 and 12 weeks in thriving breast milk–fed infant.

EPIDEMIOLOGY

Prevalence

- Physiologic jaundice: 40–60% of infants
- BFJ: 10% of breastfed infants
- BMJ: 0.5–2% of breastfed infants

RISK FACTORS

- Jaundice in first 24 hours (pathologic)
- PredischARGE elevated total serum bilirubin
- Blood type incompatibility
- Glucose-6-phosphate dehydrogenase (G6PD) deficiency
- Gestational age <36 weeks
- Previous sibling receiving phototherapy
- Cephalohematoma or significant bruising
- Exclusive breastfeeding
- Eastern Asian race

PATHOPHYSIOLOGY

- Normal physiology: Bilirubin is a breakdown product of hemoglobin.

Unconjugated bilirubin is bound to albumin, transported to the liver, and conjugated by the hepatic enzyme uridine diphosphate glucuronosyl transferase (UGT1A1). Conjugated bilirubin is transported into the small intestines via the bile ducts, where it is modified and excreted in stool. If stooling is delayed, bilirubin is deconjugated by intestinal enzymes and returned to the liver via the portal circulation (enterohepatic circulation).

- Physiologic jaundice: bilirubin levels are elevated in newborns due to several factors:
 - Increased hematocrit and red blood cell volume
 - Increased red blood cell lysis due to shorter red blood cell lifespan.
 - Impaired bilirubin excretion because of an immature hepatic UGT1A1 enzyme and increased enterohepatic circulation.
- BFJ: Lack of effective breastfeeding causes inadequate milk and calorie intake and results in decreased stooling and increased enterohepatic circulation. Infants may also be dehydrated.
- BMJ: Mechanism unclear. Hypotheses include factors found in the milk that may inhibit hepatic UGT1A1. BMJ is associated with East Asian infants who are more likely to have a UGT1A1 mutation and weight loss.

DIAGNOSIS

HISTORY

- BFJ
 - Weight loss: Infants should not lose more than 8% of their birth weight. Infants should gain 15–30 g/day after maternal copious milk production (around day 4 or 5).
 - Frequency and duration of breastfeeding: Breastfed infants should suckle at least 8–12 times/24 hours.
 - Pain with breastfeeding may indicate poor latch and therefore decreased milk transfer.
 - Urination/24 hours: urinates 1 time for each day of life until copious milk production (around 4–5 days) then at least 6 urine/24 hours
 - Stooling: changed from meconium to transitional to yellow seedy

- by 4–5 days of life. Has at least 3–4 yellow stools/24 hours.
- Maternal causes of decreased milk production: prior breast surgery, hypothyroidism, retained placenta, insufficient glandular tissue, few medications, obesity, and infertility
- BMJ
 - Infants should be in good health, gaining at least 15–30 g/day and nursing well.
 - Family history of neonatal jaundice? May indicate a genetic propensity for developing jaundice.
 - Screen for risk factors associated with pathologic jaundice:
 - Jaundice in the first 24 hours of life
 - Direct hyperbilirubinemia
 - Maternal blood type to screen for Rh or ABO incompatibility
 - Inherited hemolytic diseases (hereditary spherocytosis). Ask about family history of severe neonatal jaundice, anemia, or splenectomy.
 - Infection: maternal group B strep infection, maternal chorioamnionitis or intrapartum fever, prolonged rupture of membranes, infant fever $\geq 100.4^{\circ}\text{F}$ rectally, decreased infant feeding, increased infant sleepiness or fussiness

PHYSICAL EXAM

- Infant
 - General: thin, not thriving infant in first week associated with BFJ. Well appearing, thriving older infant associated with BMJ. An ill-appearing, grunting, tachypneic, sleepy, or fussy infant not interested in nursing should be evaluated for infection. Sleepy infants may be or become dehydrated.
 - Mucous membranes: dry mucous membranes associated with dehydration
 - Skin: Jaundice (and bilirubin levels) generally progress from head to toe but bilirubin levels estimated visually may be inaccurate. Infants with dark skin tones are especially difficult to assess.
 - Cephalohematomas and bruising are associated with increased red blood cell breakdown.
 - Abdomen: Hepatosplenomegaly is associated with metabolic or

hemolytic process or biliary obstruction. Abdominal distension may be a result of intestinal obstruction.

- Direct observation of a feeding is crucial:
 - Lips should be everted and mouth wide open approaching a 180-degree angle. As much of the areola as possible should be in the infant's mouth. The infant should have deep movement of the jaw and suck/swallow/breathe rhythmically with milk visible in infant's mouth.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- All mothers should be screened for blood and Rh type. Infants of mothers with blood type O or Rh negative need their cord blood tested for blood type and Coombs to identify risk for hemolytic anemia. These infants are at greater risk for kernicterus and need to be treated at lower total serum bilirubin levels.
- Infants should have a pre-discharge either total serum bilirubin or transcutaneous bilirubin level.
 - Bilirubin levels are interpreted based on age in hours/days and risk factors (blood incompatibility, preterm, illness). Use of a nomogram tool (such as www.bilitool.com) stratifies the infants' risk based on the American Academy of Pediatrics (AAP) bilirubin guidelines.
- Generally, minimal laboratory evaluation is needed in a healthy breastfed infant with mild jaundice in the absence of risk factors. However, BFJ and BMJ are diagnoses of exclusion. The following tests should be considered, depending on the clinical presentation:
 - Conjugated/unconjugated (direct/indirect) bilirubin level interpreted based on age and risk factors
 - May guide treatment
 - Must be measured in all infants with very early jaundice <24 hours of age
 - Recommended in all infants with persistent jaundice
 - Conjugated or direct serum bilirubin: Elevated level (>1 mg/dL or 10% of total serum bilirubin) may indicate infection, biliary obstructive disease, cholestasis, metabolic disease, or severe hemolysis.

- CBC and smear:
 - Look for polycythemia or anemia
 - Smear may assist with diagnosing hemolysis.
 - Decreases in hematocrit over time may reflect ongoing hemorrhage or hemolysis.
 - A mean corpuscular hemoglobin concentration (MCHC) of >36.0 g/dL may suggest hereditary spherocytosis.
 - Abnormal white cell count may indicate infection.
- G6PD quantitative test
 - G6PD deficiency may cause an increase in bilirubin later than other hemolytic disease and has been associated with an increased risk of kernicterus.
 - Electrolytes (especially sodium) in infant, if concern for dehydration.

DIFFERENTIAL DIAGNOSIS

- Increased bilirubin production
 - Hematologic
 - ABO or Rh isoimmunization
 - Erythrocyte enzyme defects (e.g., G6PD deficiency)
 - Erythrocyte membrane defects (e.g., hereditary spherocytosis)
 - Polycythemia
- Impaired bilirubin conjugation
 - Gilbert syndrome
 - Crigler-Najjar syndrome
- Decreased bilirubin excretion
 - Biliary obstruction
 - Biliary atresia
 - Choledochal cyst
 - Dubin-Johnson syndrome
 - Rotor syndrome
- Intestinal obstruction
 - Meconium ileus
 - Hirschsprung disease
- Congenital: transient familial neonatal hyperbilirubinemia
- Metabolic

- Hypothyroidism
- Galactosemia
- Miscellaneous
 - Dehydration
 - Sepsis
 - Cephalohematoma
 - Maternal oxytocin use

TREATMENT

- BFJ
 - Evaluate and treat for insufficient milk intake. Assess latch, position, and milk transfer. Consult a lactation expert if needed.
 - Increase frequency of effective breastfeeding to 8–12 times/24 hours.
 - Supplement with formula, pumped breast milk, or donor breast milk if needed.
 - Phototherapy if serum bilirubin levels exceed the AAP recommended threshold levels for phototherapy for full-term healthy infants based on infant's age in hours, gestational age, and neurotoxicity risk factors
 - Phototherapy may contribute to dehydration; it is essential to monitor hydration status.
 - Consider partial exchange blood transfusion with phototherapy if indicated per the AAP hyperbilirubinemia guidelines.
 - Full-term healthy infants 25–48 hours old with total serum bilirubin >19–22 mg/dL and for infants ≥48 hours old with total serum bilirubin >22–25 mg/dL
 - Consider home phototherapy if bilirubin levels close to threshold. Home phototherapy poses less of an obstruction to breastfeeding.
 - Monitor serum bilirubin levels closely until they are acceptable. Check levels after stopping phototherapy.
- BMJ
 - Monitor clinically after excluding other causes of hyperbilirubinemia.

- Encourage and support breastfeeding.
- Consider stopping breastfeeding for 24 hours (with continued pumping to preserve supply) if bilirubin levels ≥ 20 mg/dL. Level should decrease 3 mg/dL in 24 hours.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Follow up 2–3 days after discharge, earlier if infant at high risk for jaundice. Weight check, physical exam, assessment of hydration, and observation of feeding. Bilirubin level if clinically indicated.
- Close follow-up 1–2 days later if concern about milk intake or jaundice
- Patient education: Mother should be assisted with latch and positioning and be taught signs/symptoms of adequate milk intake, dehydration, illness, and jaundice.
- Late preterm/near-term infants need especially close follow-up as they have increased risk of poor milk intake.
- Visual assessment of jaundice may be inaccurate. Consider an objective measure of jaundice (e.g., total serum bilirubin or transcutaneous bilirubin level) for follow-up assessment.

INPATIENT CONSIDERATIONS

If a breastfed infant is hospitalized for jaundice, encourage continued breastfeeding if possible. For infants with BFJ, consult a lactation expert to evaluate cause for insufficient milk intake and provide assistance. The mother may need a hospital grade double electric pump to increase her milk supply.

COMPLICATIONS

- Kernicterus (bilirubin encephalopathy)
 - Acute symptoms: lethargy, hypotonia, opisthotonus, seizures, high-pitched cry
 - Chronic symptoms: hearing loss, upward gaze palsy, cerebral palsy, cognitive impairment
- Unnecessary cessation of breastfeeding
- Parental and health care provider anxiety

CODES

ICD10

- P59.3 Neonatal jaundice from breast milk inhibitor
- P59.8 Neonatal jaundice from other specified causes
- P59.9 Neonatal jaundice, unspecified

FAQ

- Q: Will jaundice cause my baby to have developmental or neurologic problems?
- A: If hyperbilirubinemia is appropriately monitored and treated, it should not cause any developmental problems.
- Q: What can be done to prevent BFJ?
- A: Early, frequent, and effective breastfeeding at least 8–12 times in 24 hours can decrease the risk of BFJ. Do not supplement unless recommended by a health care provider. Get help from a breastfeeding

expert if you have pain or the infant is not latching on or nursing well.

- Q: Should I stop breastfeeding if my baby is jaundiced?
- A: The frequency and effectiveness of breastfeeding should be increased and appropriate lactation consultation obtained for BFJ. For BMJ, temporary cessation of breastfeeding will lower total serum bilirubin; however, this recommendation should only be considered (along with formula supplementation and phototherapy) if total serum bilirubin is ≥ 20 mg/dL.

BREASTFEEDING

Jennifer A. F. Tender • Sahira Long

BASICS

DESCRIPTION

Breast milk is recognized as the optimal nutrition for infants by the American Academy of Pediatrics (AAP), the World Health Organization (WHO), the Surgeon General, and all major medical groups.

PHYSIOLOGY

- Breast milk production
 - Lactogenesis I: Milk production begins around 16 weeks prenatally.
 - Lactogenesis II: onset of copious milk secretion around 2–3 days after vaginal delivery. Under hormonal control initiated by the expulsion of placenta and decrease in progesterone levels
 - Lactogenesis III: Mature milk production (maintenance) depends on autocrine (local) control. The amount of milk removed influences milk volume. If milk is not removed, a protein (feedback inhibitor of lactation) accumulates and inhibits prolactin release.
 - Prolactin is released from the anterior pituitary in response to nipple stimulation and triggers milk secretion into the lumen of breast alveoli.
 - Oxytocin is released from the posterior pituitary gland, causing ejection of milk into the breast ducts (milk ejection reflex).
 - Let-down can be triggered by physical stimulation of the breast or by mental stimulation such as hearing a baby cry.
- Composition
 - Largely independent of maternal diet, except for fatty acids and water-soluble vitamins
 - Colostrum contains high levels of secretory immunoglobulin A for immune protection. Lactoferrin stimulates meconium passage and promotes colonization with protective lactobacillus bifidus.
 - High whey-to-casein ratio
 - Milk changes within a feed and throughout the day. Hindmilk and

milk at night contains higher fat and calories.

- Risks of not breastfeeding:
 - For child: increases risk of postneonatal death; gastroenteritis, necrotizing enterocolitis for preterm infants, lower respiratory infections, acute otitis media, bacterial meningitis, obesity, sudden infant death syndrome (SIDS), asthma, leukemia, and type II diabetes
 - For mother: increases risk of ovarian and breast cancer, cardiovascular disease, and postpartum hemorrhage. Loss of benefit of lactational amenorrhea and child spacing
 - For family: increased expenditures, more workdays lost to care for ill child
 - For society: increases environmental impact and costs at least \$13 billion annually related to an increase in childhood diseases

EPIDEMIOLOGY

Prevalence

- 79% of infants in the United States initiate breastfeeding, according to 2013 data from the Centers for Disease Control and Prevention.
- At 3 months, 41% breastfed exclusively.
- At 6 months, 49% breastfed, 16% exclusively
- At 12 months, 27% breastfed.
- Racial and economic disparities in breastfeeding exist; lower rates among African American women and women living in poverty

RISK FACTORS

- Contraindications to breastfeeding:
 - Infant with classic galactosemia
 - Maternal conditions:
 - HIV (in industrialized countries)
 - Illicit drug use
 - Active, untreated tuberculosis
 - Herpes simplex virus lesions on breast
 - HTLV-I– or HTLV-II–positive
 - Exposure to radioactive material, while there is radioactivity in the milk

- Use of some medications, such as cytotoxic drugs
- Infant conditions that may interfere with breastfeeding:
 - Prematurity
 - Low birth weight
 - Hypotonia
 - Cleft lip or palate
 - Ankyloglossia (tongue-tie)
- Maternal conditions that may interfere with breastfeeding:
 - History of breast surgery
 - Abnormal breast shape (glandular insufficiency)
 - Inverted nipples
 - Medications that inhibit lactation
 - Endocrine: infertility, hypothyroidism, polycystic ovary, retained placenta, Sheehan syndrome, obesity
- Common reasons cited for early termination of breastfeeding:
 - Perceived insufficient milk supply
 - Poor latch
 - Sore nipples
 - Returning to work or school

DIAGNOSIS

HISTORY

- Experience breastfeeding previous children
- Prior breast surgery
- Breast enlargement during pregnancy
- Frequency and duration of feedings
 - Feed >8–12 times a day in the 1st few weeks of life, with no more than 4 hours between feedings.
 - Newborns typically need >8–10 minutes of active suckling to “empty” a breast.
- Signs of adequate milk intake:
 - Adequate hydration: 1 wet diaper for each day of life until milk “comes in” around day 4 of life; then ≥ 6 wet diapers per 24 hours
 - Adequate nutrition: stool changes from meconium to transitional to

yellow seedy by 4th day of life. Infant typically has >3–4 yellow stools/24 h in the first month. Stool pattern often changes at 1 month, and infant may only stool every 3–7 days.

- Infant may lose up to 8% of birth weight until milk “comes in” around day 4 or 5.
- Infant should gain 15–30 g/day and be back to birth weight by 10–14 days.
- The WHO growth charts better represent typical growth of breastfed infants.
- Breast/nipple pain: Women may experience discomfort at first, but breastfeeding should not hurt. The most common cause of pain is poor latch. Other causes include candidal infection of the nipple, or mastitis.

PHYSICAL EXAM

- Direct observation of a feeding is crucial:
 - Examine the infant’s oropharynx for thrush, ankyloglossia, or anatomic abnormalities.
 - Examine the mother’s breasts for scars (prior surgery), nipple inversion, erythema (possible candida), or cracking (poor latch).
 - Infant feeding cues: Rooting, lip smacking, and sucking are early signs of hunger; crying is a late sign.
 - The mother should be positioned comfortably and not have to bend down.
- Two types of infant positioning:
 - Infant-led: The mother is semireclined in bed with the infant’s head at breast height. The infant initiates the latch.
 - Mother-led:
 - Cross-cradle: easy visualization of latch. Mother holds her baby with the arm opposite the breast she is using, holds the back of the baby’s neck, and brings the baby to breast height. Her other hand supports and compresses her breast. The infant should be in a straight line with ear, shoulder, and hip aligned.
 - Other positions include cradle, football, and sidelying.
- For an effective latch, the mother touches the infant’s nose or upper lip to her nipple and waits until the infant opens wide. She brings the infant to her breast. She may compress her breast with her thumb by

the infant's nose parallel to upper lip.

- Evaluating the latch: Lips should be everted and mouth wide open approaching a 180 degrees angle. As much as possible of the areola is in the infant's mouth. More of the areola shows above the infant's mouth than below. The mother's nipple should not be distorted after the infant suckles.
- Signs of good milk transfer: Infant relaxed and breasts less full after nursing, infant has deep movement of the jaw and sucks/swallows/breathes rhythmically, milk visible in infant's mouth.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Total/direct bilirubin level, if clinically indicated
- Electrolytes (especially sodium) in infant, if there is concern for dehydration

TREATMENT

MEDICATION

- Vitamin D, 400 IU/24 h orally for all infants starting at the first visit if not given at hospital discharge, even if supplementing with formula
- The AAP Section on Breastfeeding recommends starting iron-rich complementary foods at 6 months, whereas the AAP Committee on Nutrition recommends elemental iron, 1 mg/kg/day, from age 4 months until iron-rich food is introduced. Elemental iron at 2 mg/kg/day starting by age 1 month is recommended for preterm infants.
- Thrush or candidal infection of the nipples requires simultaneous treatment of both mother and infant with a topical antifungal agent and thorough washing of all artificial nipples. Treatment options include nystatin or oral fluconazole for resistant cases.
- Most maternal medications are compatible with breastfeeding. Mothers should not breastfeed if using illicit or cytotoxic drugs, or radioactive compounds until cleared from the mother's milk. Choose medications with short half-lives, high protein binding, low oral bioavailability, high molecular weight, and low lipid solubility. Refer to databases

such as the National Library of Medicine's LactMed.

ADDITIONAL TREATMENT

General Measures

- Cracked nipples should be treated by correcting the latch. Women can apply breast milk or purified lanolin. Keep nipples dry.
- Engorgement can be relieved by frequent and effective feeding or pumping, breast massaging, and applying cool compresses.
- Clogged milk ducts may be treated with warm compresses, frequent emptying of the breast, massaging the area, and varying feeding positions.
- Pumping may help with inverted nipples. A nipple shield can be tried if inverted nipples cause trouble latching. Prolonged nipple shield use is controversial, as concerns exist regarding their impact on milk supply; thus their use should be limited to a short period of time (~1 month).
- Mastitis can be treated with antibiotics, frequent and effective feeding and maternal rest.
- Infants with ankyloglossia that affects latch or impedes milk transfer should be referred for frenotomy.

COMPLEMENTARY & ALTERNATIVE THERAPIES

- Herbs traditionally used to try to increase milk supply (galactagogues) include the following:
 - Fenugreek (*Trigonella foenum-graecum*): taken as tea or capsules. May be effective; probably safe in moderate doses
 - Milk thistle (*Silybum marianum*): usually taken as a tea; increased milk supply in one study (no available safety data support use)

INPATIENT CONSIDERATIONS

If a breastfed infant is hospitalized, encourage continued breastfeeding if possible. If the infant is not able to breastfeed, provide a hospital-grade double electric pump and encourage pumping at least 8 times/24 h.

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- In general, 2–3 days after hospital discharge. Weight check, physical exam, and observation of feeding

- Close follow-up 1–2 days later if concern about milk intake or jaundice then as needed
- At age 2–3 weeks: weight check and breastfeeding support
- Patient education: Mother should be assisted with latch and positioning and should know signs/symptoms of adequate milk intake (urine output, stooling), dehydration, and illness.

DIET

- For the infant:
 - Except for vitamin D, no food or fluid other than breast milk is needed for the first 6 months of life.
 - After 6 months, iron-rich foods and other complementary foods may be introduced.
- For the mother:
 - ~500 kcal/day are used for breastfeeding.
 - Women should avoid breastfeeding for at least 2 hours after alcohol consumption.
 - If infant has G6PD deficiency, mother should avoid fava beans and certain medications.

COMPLICATIONS

- Infant
 - Hyperbilirubinemia
 - Dehydration/hyponatremia
- Mother
 - Engorgement
 - Clogged milk duct
 - Mastitis
 - Candidal nipple infection
 - Cracked nipples

CODES

ICD10

- P92.5 Neonatal difficulty in feeding at breast
- Q38.1 Ankyloglossia
- P92.6 Failure to thrive in newborn

FAQ

- Q: How do I know if my baby is getting enough milk?
- A: Look for signs of effective feeding as described earlier. Your baby should suck deeply and rhythmically during a feeding, seem satisfied after a feeding, and gain approximately 15–30 g/day. A baby’s elimination pattern may be variable, but, in general, most adequately breastfed infants will have 4 or more stools a day by 4 days of life.
- Q: How do I alleviate breast pain with nursing?
- A: Most pain is due to poor latch. Ensure deep latch. Compress the breast and make sure the baby takes as much of the areola as possible.

If stinging occurs throughout nursing, consider candidal infection. Seek advice from a lactation expert if pain does not improve.

- Q: How can I increase my milk supply?
- A: Increase frequency and effectiveness of feeding or pumping. Place infant skin to skin. Pump after nursing sessions. If pumping often, use a hospital-grade double pump. Get plenty of sleep and try to reduce stress.
- Q: How long can expressed breast milk be stored safely (applies to term infants only)?
- A: At room temperature (up to 77°F) for 3–6 hours. In the back of a refrigerator for 3 (ideal)–8 days if very clean container. For 6–12 months if in the freezer. Thawed breast milk should be refrigerated and used within 24 hours of thawing.
- Q: How long should breastfeeding be continued?
- A: The AAP recommends breastfeeding at least until 12 months of age, and as long afterward as is mutually desired. The WHO recommends breastfeeding for at least 2 years. Exclusive breastfeeding is nutritionally adequate for the first 6 months.
- Q: Can adoptive mothers breastfeed?
- A: Induced lactation is possible. Lactation experts should be consulted.

BREATH-HOLDING SPELLS

Nailah Coleman

BASICS

DESCRIPTION

- Breath-holding spells are the general term for emotionally provoked attacks that occur in young children. These attacks can progress from a strong emotion to “breath holding” to decreased sensorium and either limpness or stiffness, which can appear as seizure-like activity.
- Disease essentials
 - Provoked by anger, pain, or frustration
 - Association with altered respiratory effort
 - Results in decreased muscle tone
 - Can be classified as simple (brief, no loss of consciousness) or severe (prolonged, associated loss of consciousness)
- Subtypes
 - Cyanotic (80%)
 - Classic breath-holding spells
 - Typically associated with anger
 - Progress from crying to exhalation to apnea and syncope to decreased muscle tone and falling
 - May also note generalized clonic jerks, opisthotonos, and bradycardia
 - Ages: 6 months to a peak at 2 years, with resolution by 5 years
 - Pallid (20%)
 - Typically associated with pain, frustration, or surprise
 - Progress from quieting to apnea (at the end of expiration) to syncope to decreased muscle tone and falling
 - May also note clenched hands and clonic jerks and bradycardia

EPIDEMIOLOGY

- Incidence: not reported
- Prevalence: 4.6% (severe), up to 27% (simple)
- No gender difference

- 20–35% have a positive family history
- Age/frequency
 - Median age of onset 6–12 months of age
 - Typically ages 1–5 years but can occur up to 7 years of age
 - Usually resolve by school age
 - Frequency
 - Can occur several times per day to only once a year
 - Age of peak frequency of spells is from 1–2 years of age.

RISK FACTORS

- Underlying autonomic regulatory dysfunction
- Inheritance
 - 20–35% of patients with breath-holding spells have a positive family history.
 - 11% of patients with epilepsy or other chronic but nonneurologic disorder have a positive family history of breath-holding spells.
 - For 80% of patients with severe spells and a positive family history, the affected family members are mainly on the maternal side.
 - An autosomal dominant trait with reduced penetrance has been noted in some.

GENERAL PREVENTION

- There are no known methods, medications, or treatments for preventing breath-holding spells.
- Although the term breath-holding spells implies volition, these attacks are involuntary and reflexive.
- For a variety of reasons, emotional outbursts are common in this age group; however, appeasing a child to prevent a spell is not recommended as it may lead the child to develop other, similar-appearing behaviors encouraging parental concession.

PATHOPHYSIOLOGY

- Cyanotic breath-holding spells
 - Syncope due to a Valsalva maneuver increasing the intrathoracic pressure, decreasing cardiac blood return and eventually cardiac output, which causes cerebral hypoperfusion and unconsciousness
- Pallid breath-holding spells

- Abnormal vagal response to emotional stimulation causing bradycardia and/or asystole, leading to decreased cardiac output and cerebral ischemia and unconsciousness

ETIOLOGY

Always provoked by anger, pain, or frustration

COMMONLY ASSOCIATED CONDITIONS

- No definitive associated conditions
- There have been reports of some children with breath-holding spells going on to have syncope and/or seizures.
- Some studies have noted an increased prevalence of anemia in children with breath-holding spells; the anemia and spells improved over time with iron treatment. Although these findings also coincide with the expected timing for resolution of breath-holding spells, anemia might complicate an individual child's picture.

DIAGNOSIS

HISTORY

- Important to elicit history of
 - Provocation by anger, pain, or frustration
 - Altered respiratory effort, decreased responsiveness, and altered muscle tone (either limpness or stiffness)
 - Lack of trauma
 - Not volitional

PHYSICAL EXAM

- Vital signs: normal on exam; perform orthostatic blood pressures
- Focal findings: none, normal cardiac, and neurologic exams

DIFFERENTIAL DIAGNOSIS

- Syncope: not usually preceded by crying; altered muscle tone typically accompanied by efforts to prevent falling
 - Neurocardiogenic (vasovagal syncope, fainting)
 - Associated with bradycardia, vasodepression, and/or hypotension leading to decreased cerebral perfusion

- More common in adolescents
- Cardiac
 - Dysrhythmias
 - Prolonged QT syndrome
 - Wolff-Parkinson-White syndrome
 - Complete heart block
 - Structural
 - Hypertrophic cardiomyopathy
 - Severe pulmonary or aortic stenosis
 - Coronary artery aneurysm
 - Anomalous origin of the left coronary artery
 - Pulmonary hypertension
 - Myxoma
- Orthostatic
- Neuropsychiatric
 - Panic attacks or hyperventilation syndrome
 - Benign paroxysmal vertigo
 - Cataplexy
 - Hysterical syncope
- Cough
 - Most common in asthmatics
 - Increased intrapleural pressure from coughing leads to decreased venous return and eventually decreased cardiac output and cerebral perfusion
- Metabolic: hypoglycemia
- Epilepsy or epilepsy equivalent: altered muscle tone precedes color change; abnormal EEG
- Central or obstructive apnea: not typically associated with crying; abnormal sleep study
- Brainstem pathology such as tumor or malformation: other abnormal findings on history and exam
- Familial dysautonomia: other abnormal findings on history and exam
- Rett syndrome: other abnormal findings on history and exam

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- If anemia is of concern, CBC should be obtained.
- If hypoglycemia is high on differential acutely, plasma glucose should be obtained.

Imaging

- No specific imaging is necessary to diagnosis breath-holding spells. However, if trauma, brain pathology, or abnormal cardiac morphology is suspected, the following imaging could be obtained:
 - Head CT
 - Brain MRI
 - Cardiac echocardiogram (EKG)
 - Cardiac MRI
 - Chest x-ray—evaluate lung hyperinflation in asthmatics (not needed for diagnosis)

Diagnostic Procedures/Other

- For evaluation of potential dysrhythmias, consider the following:
 - EKG
 - Holter monitor
 - Electrophysiology study
 - Stress test
- For evaluation of epilepsy or other neuroelectric disorder, consider an EEG.
- For evaluation of apnea, consider a sleep study.

TREATMENT

MEDICATION

- No medication has been found to be definitively useful in preventing or treating breath-holding spells.
- It is important to note that breath-holding spells can occur in the presence of other conditions that can present with syncope and seizure-like activity. Should those conditions be present or suspected, additional treatments may be necessary.
- Multiple studies have evaluated the use of various medications to

prevent and/or treat breath-holding spells. However, they are limited by inadequate sample size, power, and/or statistical significance.

- Iron therapy may be useful in breath-holding spells, particularly in children found to be anemic and/or iron deficient.
- Atropine and pacemakers have been used for those with severe bradycardia to good effect.
- Fluoxetine was noted to improve pallid breath-holding spells in another small study.

ADDITIONAL TREATMENT

Reassurance is the primary treatment.

ISSUES FOR REFERRAL

Referral is not necessary unless diagnoses on the differential could not be excluded or if the spells do not conform to the normal pattern and/or the normal age range.

INPATIENT CONSIDERATIONS

- Inpatient hospital admission for breath-holding spells is not necessary as they are a benign condition. However, if other diagnoses are being considered, if the patient required resuscitation, or if the patient requires ongoing support, an inpatient hospital admission and medical evaluation is warranted.
- Should an inpatient admission be warranted, other diagnoses should be considered and evaluated.

ADDITIONAL TREATMENT

- Should loss of consciousness occur with a breath-holding spell, it is important to place the child on his or her side and ensure a clear airway.
- With the potential for altered muscle tone and additional injury, parents should ensure the environment around the child is safe.

ONGOING CARE

PATIENT EDUCATION

The primary goal for ongoing care is parental education as to the natural

history of breath-holding spells.

PROGNOSIS

- As they are a benign condition, isolated breath-holding spells have an excellent prognosis without sequelae.
- Breath-holding spells typically resolve by school age.
- Should breath-holding spells not follow the typical course or time frame, additional diagnoses should be considered (could impact the prognosis).

COMPLICATIONS

Although some have postulated the potential for the development of syncope, epilepsy, and neurodevelopmental disorders, no definitive associations have been found.

FAQ

- Q: What is the age range of the typical child with breath-holding spells?
- A: The typical age range of the child with breath-holding spells is 1–5 years of age.
- Q: What is the typical provocation and pathophysiology of the most common type of breath-holding spells?
- A: The most common breath-holding spells are cyanotic (80%). These are typically provoked by anger, which leads to crying, a Valsalva maneuver, decreased cardiac return, decreased cardiac output, decreased cerebral perfusion, and syncope.
- Q: Is there a genetic basis for breath-holding spells?
- A: An autosomal dominant trait has been found in some patients with breath-holding spells.
- Q: What are the common diagnostic tools used to diagnose breath-holding spells?
- A: Breath-holding spells are diagnosed primarily by obtaining a good history and performing a physical exam, the latter of which should be normal. Additional diagnostic tools should only be used if a separate diagnosis is being considered due to unusual history or abnormal physical exam findings.
- Q: How are breath-holding spells managed and prevented?
- A: Breath-holding spells require reassurance provided to the family about acute management and their natural history. At this time, there is no way to prevent breath-holding spells.

BRONCHIOLITIS (SEE ALSO: RESPIRATORY SYNCYTIAL VIRUS)

Alan R. Schroeder

BASICS

DESCRIPTION

Acute infection of the lower respiratory tract in infants and young children leading to mononuclear infiltration of the bronchiolar epithelium, causing edema and mucus plugging of the small airways

EPIDEMIOLOGY

- Peak season is November through April, with some variation by state in the United States (begins earlier in the Southeast).
- Most common cause of infant hospitalization
 - ~150,000 hospitalizations/year in the United States
 - Hospitalization rates tripled from 1980 to 1997 but have decreased over the last decade.
- Most recent estimate ~15 hospitalizations/1,000 person-years for children <2 years of age
- Approximately, 1/3 of all children will get bronchiolitis in the first 2 years of life.

ETIOLOGY

- Respiratory syncytial virus (RSV) is the most common causative organism, but other organisms include the following:
 - Human rhinovirus
 - Adenovirus
 - Human metapneumovirus
 - Enterovirus
 - Coronaviruses
 - Influenza viruses
 - Parainfluenza viruses
 - Mycoplasma pneumoniae
- Majority of bronchiolitis cases are caused by one virus, but viral

coinfections (2 or more viruses) may occur in ~1/4 of cases.

COMMONLY ASSOCIATED CONDITIONS

- Patients at high risk of severe bronchiolitis:
 - Premature infants (<36 weeks' gestation)
 - Young infants (<2–3 months of age)
 - Congenital heart disease
 - Chronic lung disease (including bronchopulmonary dysplasia [BPD])
 - Low birth weight
 - Cystic fibrosis
 - Immunodeficiency
 - Neuromuscular diseases
 - Trisomy 21
- Exposure to cigarette smoke is a risk factor for more severe disease.

DIAGNOSIS

HISTORY

- Generally begins as an upper respiratory infection with rhinorrhea but spreads to lower respiratory tract within 2–3 days
- Often multiple sick contacts in household
- Variable timing of symptoms. The unpredictability of the time course of the disease may be partly explained by viral coinfections.
- Poor feeding and increased insensible water loss may lead to dehydration and decreased urine output.
- Fever in approximately 50% of patients
- Restlessness or lethargy may indicate impending respiratory failure (hypoxemia and/or CO₂ retention).
- Apnea can be sole presenting sign in younger infants.

PHYSICAL EXAM

- General appearance
 - Interactive versus ill-appearing
 - Paroxysmal cough common
- HEENT exam

- Nasal congestion with copious secretions
- Otitis media is common.
- Pulmonary exam
 - Pattern of breathing: apnea or periodic breathing
 - Tachypnea: $>70/\text{min}$ is associated with severe illness.
 - Grunting, nasal flaring, and accessory muscle use (supracostal, intercostal, subcostal retractions) are signs of more severe disease.
 - Thoracoabdominal asynchrony (“abdominal breathing”)
 - Hyperresonance to percussion
 - On auscultation: diffuse, high-pitched heterophonic wheezing; prolonged expiratory phase; inspiratory crackles; diffuse rhonchi
 - Lung exam can change rapidly.
- Other findings:
 - Signs of dehydration
 - Poor peripheral perfusion (delayed capillary refill time, cool extremities, weak peripheral pulses, mottling of skin) is a concerning sign.
 - Liver and spleen often caudally displaced by hyperinflated lungs.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- The majority of bronchiolitis cases do not warrant any laboratory investigation.
- Blood gas
 - In severe cases, can help determine acid–base status and effectiveness of ventilation; however, decisions to escalate support can generally be based on clinical assessment.
 - Arterial PO_2 generally does not add much information beyond that provided by a pulse oximeter.
- CBC +/- differential: low yield; a bandemia common with RSV
- Serum electrolytes: On occasion, may assist with assessment of hydration (BUN, creatinine), and hyponatremia rarely occurs due to antidiuretic hormone release.
- Viral testing
 - Rarely changes management
 - Some hospitals require it for cohorting, but can be misleading given

the broad number of potentially causative viruses and the high frequency of viral coinfections.

- Best obtained by nasopharyngeal aspirate; can also be obtained by nasal swab
- Viral cultures are accurate, but may take up to 14 days for results.

Imaging

- Chest radiography is of little value in the majority of bronchiolitis cases, and multiple recent efforts have attempted to limit unnecessary radiographic testing.
- When obtained, findings may include the following:
 - Hyperinflation, flattened diaphragms
 - Peribronchial thickening
 - Patchy or more extensive atelectasis
 - Possible collapse of a segment or a lobe
 - Diffusely increased interstitial markings are common.

DIFFERENTIAL DIAGNOSIS

- Pneumonia (viral or bacterial)
- Foreign body aspiration
- Asthma
- Gastroesophageal reflux (GER)
- Pulmonary edema (e.g., congestive heart failure)
- Cystic fibrosis
- Airway abnormalities (tracheomalacia or bronchomalacia)

TREATMENT

GENERAL MEASURES

- There is substantial variation in the use of diagnostic testing, hospitalization, and treatments, but bronchiolitis is a self-limited condition that generally improves without intervention.
- Most cases are mild and may be managed at home.
 - Ensure adequate fluid intake.
 - Antipyretics may be used for comfort—given concerns of association between acetaminophen use and asthma, consider

- ibuprofen as first line in infants >6 months of age.
- For rhinorrhea, nasal suction with bulb syringe may be of use.
 - Supplemental oxygen
 - Can be given humidified via nasal cannula, high-flow nasal cannula, face mask cannula, noninvasive positive pressure ventilation, or via endotracheal tube
 - Should be titrated to respiratory distress and/or oxygen saturation
 - Home oxygen use is an alternative and has been shown to successfully and safely reduce hospital admission rates from the emergency department.
 - Pulse oximetry
 - Continuous pulse oximetry can be useful as a monitoring device in order to titrate oxygen therapy, but it may also prolong length of stay by contributing to the overdiagnosis of hypoxemia (i.e., transient desaturations in otherwise comfortable infants).
 - Consider intermittent pulse oximetry use in infants who are not requiring oxygen.
 - The following medications/therapies are of no proven benefit in bronchiolitis and should be avoided:
 - Corticosteroids (systemic or inhaled)
 - Ipratropium bromide
 - Leukotriene modifiers

INPATIENT CONSIDERATIONS

- Common indications for hospitalization include the following:
 - Need for IV hydration
 - Need for frequent suctioning
 - Moderate to severe distress (respiratory rate >60–70 breaths/minute, accessory muscle use, agitation, cyanosis, poor perfusion)
 - Apnea
- Although hypoxemia is often used as an indication for hospitalization, exact oxygen saturation thresholds are uncertain. The American Academy of Pediatrics (AAP) suggests using supplemental oxygen for saturations <90%.
- Hydration
 - Intravenous crystalloid boluses of 10–20 mL/kg should be given to

infants with signs of poor perfusion.

- For infants who are unable to maintain adequate PO intake, hydration can be maintained with nasogastric feeds or maintenance IV fluids. Because of the risk of hyponatremia, hypotonic fluids should be avoided.
- Suctioning
 - Nasal suctioning may improve work of breathing and facilitate feeding. Noninvasive suctioning (i.e., a nasal aspirator placed over the naris) is preferable to deep suctioning, which may cause trauma to the nasopharynx and worsen edema.
- Aerosols
 - β -Adrenergic agonists have no clear benefit in bronchiolitis. While some trials have suggested transient improvements in respiratory scores, none has demonstrated any impact on clinically meaningful outcomes such as hospitalization rates or hospital length of stay.
 - Racemic epinephrine, with its α -adrenergic properties, holds more promise than albuterol given that bronchiolitis is characterized more by airway edema than bronchospasm. Racemic epinephrine has been demonstrated in some studies to reduce hospital admission rates compared to placebo and to shorten length of stay when compared to albuterol.
 - Neither β - or α -adrenergic agonists are recommended by the AAP for routine use.
 - Preliminary studies on nebulized hypertonic saline (HTS) suggest that it might reduce length of stay. Although most studies use HTS in combination with albuterol or racemic epinephrine, at least one large study has suggested that these adjuvants are not necessary.
 - If aerosols are to be used in bronchiolitis, careful attention should be paid to the clinical exam before and after administration (preferably with the use of a respiratory score) in order to support their ongoing use.
- Antimicrobials
 - Antibiotics are overused in bronchiolitis and should be avoided in most cases.
 - Special considerations include the following:

- Respiratory failure requiring intubation, in which case a substantial portion of patients have bacteria isolated from respiratory cultures
 - Urinary tract infection
 - Otitis media
- See [RSV](#) chapter for discussion of ribavirin and RSV immunoprophylaxis.
- The following inpatient medications/therapies are of no proven benefit in bronchiolitis and should be avoided:
 - Corticosteroids (systemic or inhaled)
 - Ipratropium bromide
 - Leukotriene modifiers
 - Methylxanthines (theophylline, aminophylline)
 - Recombinant human DNase
 - N-Acetylcysteine
 - Chest physiotherapy

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Most infants with no underlying disease improve within 1 week.
- A fraction of infants (~20%) will have symptoms for 3 weeks or more.
- Clinical course is prolonged in younger infants (<6 months) and those with comorbid conditions.

PROGNOSIS

- For most previously healthy infants, the prognosis is good.
- A small fraction of infants, especially young or chronically ill ones, need support in the ICU with positive pressure ventilation.
- Mortality rates are very low (<0.1%).
- Infants with chronic underlying disease may have a protracted course and are at risk for repeated hospitalizations.
- Although up to 50% of infants with bronchiolitis develop subsequent episodes of wheezing, the direction of causality between bronchiolitis

and asthma is unclear.

COMPLICATIONS

ALERT

Almost all infants with bronchiolitis get better and do not need testing or therapies.

Be aware of viral coinfections—1/4 of hospitalized patients with bronchiolitis have evidence of infection with at least 2 viruses.

- J21.0 Acute bronchiolitis due to respiratory syncytial virus
- J21.8 Acute bronchiolitis due to other specified organisms

FAQ

- Q: How did my child get bronchiolitis?

- A: Viral bronchiolitis is a common, seasonal, respiratory tract infection that is easily transmissible. It is acquired in much the same way as the common cold.
- Q: Can my child become reinfected?
- A: Children can become reinfected with RSV bronchiolitis, and infection can occur more than once during the same respiratory season. Furthermore, some patients can get two viral infections at the same time.
- Q: Do patients with bronchiolitis need to be isolated?
- A: Ideally, all patients with bronchiolitis are kept in isolation from other patients with and without bronchiolitis. If cohorting is necessary, patients with the same virus can be roomed together, although contact precautions should still be taken.
- Q: Will my child develop asthma?
- A: There is an ~50% chance that a patient with bronchiolitis will wheeze again. However, it is not clear whether the virus causes asthma or if infants who are predisposed to asthma are more likely to get bronchiolitis.

BRONCHOPULMONARY DYSPLASIA (BPD)

Vineet Bhandari • Anita Bhandari

BASICS

DESCRIPTION

- A chronic lung disease (CLD) of premature infants defined as the need for supplemental O₂ for 28 days and a need for supplemental oxygen +/-positive pressure at 36 weeks postmenstrual age (PMA).
- It is categorized as mild, moderate, and severe, based on the following at 36 weeks PMA or discharge (whichever comes first).
 - Mild: breathing room air
 - Moderate: need for <30% oxygen
 - Severe: need for >30% oxygen, with or without positive pressure ventilation or continuous positive pressure

EPIDEMIOLOGY

BPD is the most common CLD in infants. Infants with birth weight (BW) <1,250 g account for 97% of all patients with BPD. Prevalence based on BW:

- 501–750 g: 42%
- 751–1,000 g: 25%
- 1,001–1,250 g: 11%
- 1,251–1,500 g: 5%

RISK FACTORS

- Infants with gestational age (GA) <28 weeks and BW <1,000 g
- Invasive ventilation
- Exposure to hyperoxia
- Sepsis (in utero and postnatal; local/systemic)
- Genetic predisposition

GENERAL PREVENTION

- Prevention of premature birth
- Noninvasive ventilation approaches

- Avoidance of hyperoxia
- Decreasing perinatal infections

PATHOPHYSIOLOGY

- Multifactorial with gene–environmental interactions
- Antenatal (AN)—chorioamnionitis
- Postnatal (PN)—ventilator injury, hyperoxia, and sepsis
- AN and PN factors act on a genetically predisposed immature lung, causing release of multiple molecular mediators of inflammation, resulting in activation of cellular death pathways, followed by resolution or repair.
- Repair of the injured developing lung results in decreased alveolarization and dysregulated pulmonary vasculature, the pathologic hallmarks of BPD.

DIAGNOSIS

HISTORY

- Family: premature birth, asthma
- AN: pregnancy-induced hypertension, preterm/prolonged rupture of membranes, chorioamnionitis, steroids
- Perinatal: resuscitation at birth
- PN: GA, BW, small for GA (SGA), respiratory distress syndrome (RDS), surfactant use, duration of invasive/noninvasive ventilation, supplemental O₂

PHYSICAL EXAM

- Early phase (up to 1 PN week): normal to severe RDS (i.e., tachypnea, dyspnea)
- Evolving phase (>1 PN week to 36 weeks PMA): increasing respiratory distress and FiO₂
- Established phase (>36 weeks PMA): tachypnea, dyspnea, crackles, stridor (subglottic stenosis), wheezing, “BPD spells” (tracheobronchomalacia), evidence of pulmonary hypertension (PH), gastroesophageal reflux (GER), poor growth parameters

DIAGNOSTIC TESTS & INTERPRETATION

Labs: Initial Lab Tests

Blood gases: monitoring of acid–base status, hypo/hyperoxia, hypo/hypercapnia

Labs: Follow-Up Tests & Special Considerations

- Echocardiogram: evidence of PH-tricuspid regurgitant jet, flattening of the interventricular septum, accelerated pulmonary regurgitation velocity, right atrial enlargement, right ventricular hypertrophy and dilation
- Cardiac catheterization in selective infants, to confirm PH
- Pulmonary function testing: Majority have abnormal spirometry with decreased forced expiratory flow at 1 second (FEV_1) and decreased small airway expiratory flows (FEF, 25–75%) and impaired diffusion capacity. Majority of studies reveal no decrease in exercise capacity in former premature babies, although response to exercise differs.

Imaging: Initial Approach

Chest radiography: Early—reticular-granular pattern with air bronchograms (RDS); evolving—pulmonary edema, atelectasis; established—hyperinflation, increased interstitial markings, cysts

Imaging: Follow-Up & Special Considerations

CT scan: persistent findings which include linear densities, subpleural triangular densities, and emphysema

Diagnostic Procedures/Other

- Bronchoscopy for subglottic stenosis, trachea/bronchomalacia
- Sleep studies for persistent hypoxia and suspected central or obstructive apnea
- pH probe for GER

DIFFERENTIAL DIAGNOSIS

- Pneumonia
- Aspiration
- Congenital heart disease
- Wilson-Mikity syndrome
- Interstitial lung disease

- Surfactant protein deficiency
- Pulmonary lymphangiectasia

TREATMENT

MEDICATION

- O₂ supplementation
 - Prevention of hypoxia and as a pulmonary vasodilator
 - Early/evolving phases: Titrate FiO₂ by pulse oximeter 88–92%, generally, >85–<95%.
 - Established phase: generally ~95%, for prevention of PH
- Methylxanthines
 - Acts as a respiratory stimulant, increases diaphragmatic contractility, weak bronchodilator and diuretic
 - Caffeine use has been associated with decreased BPD and improved neurodevelopmental outcomes.
 - Early/evolving phases: caffeine citrate (IV/PO) 20 mg/kg loading dose, 5 mg/kg/24 h maintenance dose
 - Side effects include feeding intolerance, tachycardia
- Vitamin A
 - Helpful in maintaining epithelial cell integrity of the respiratory tract
 - Early/evolving phases: 5,000 IU IM 3 times per week for 4 weeks
- Steroids
 - Decreases inflammation, pulmonary edema
 - Evolving phase: Dexamethasone (IV/PO, 0.5 mg/kg/24 h × 2 days, then 0.25 mg/kg/24 h × 2 days, then 0.15 mg/kg/24 h × 1 day) may be used to assist with extubation attempts after 3–4 PN weeks.
 - Established phase: Prednisolone (PO, 2 mg/kg/24 h × 5 days, then 1 mg/kg/24 h × 3 days, then 1 mg/kg/24 h every other day for 3 doses) may be helpful in weaning oxygen.
 - Side effects include hyperglycemia and hypertension in the short term.
- Diuretics
 - Evolving/established phases: furosemide (PO/IV, 1–2 mg/kg/24 h or

every other day; chlorothiazide (PO/IV, 20–40 mg/kg/24 h) alone or with spironolactone (PO, 2–4 mg/kg/24 h) for transient improvement of lung function

- Side effects include electrolyte abnormalities, nephrocalcinosis, and osteopenia of prematurity.
- Bronchodilators
 - Evolving/established phases: Inhaled β -agonists (e.g., albuterol 1.25–2.5 mg given via nebulizer or 2 puffs [180 mcg] given via MDI with spacer device, every 3–4 hours as needed) are effective treatment for reversible bronchospasm, although safety and efficacy of long-term use has yet to be established.
 - Muscarinic antagonists (e.g., ipratropium bromide 250–500 mcg via nebulizer or 18 mcg/puff via MDI with spacer device, every 6–8 hours as needed) may be useful adjuncts, especially in patients who are not significantly responsive to albuterol. It may be better tolerated than albuterol in patients with significant tracheomalacia.
 - Cromolyn, although not a bronchodilator, is often used for its anti-inflammatory effects and has a low side-effect profile. It has no role in prevention of BPD.

ALERT

- Many patients have oral aversion and feeding difficulties; close monitoring of growth and nutrition is recommended.
- Patients <2 years of age are candidates for respiratory syncytial virus immune globulin injections (palivizumab; Synagis), and those older than 6 months of age should be offered influenza immunization.
- Childhood immunizations are based on chronologic age rather than corrected age.
- There are no evidence-based guidelines regarding diuretic use or weaning off of supplemental oxygen therapy in established BPD.

ADDITIONAL TREATMENT

- Ventilator strategy
 - Early phase: Avoid intubation; if intubated, give early surfactant (<2 hours of PN life), use short inspiratory times (0.24–0.4 second), rapid rates (40–60/min), low peak inspiratory pressure (14–20 cm

H₂O), moderate positive end-expiratory pressure (4–6 cm H₂O), and tidal volumes (3–6 mL/kg), with blood gas targets pH 7.25–7.35, PaO₂ 40–60 mm Hg, PaCO₂ 45–55 mm Hg; “rescue” high-frequency ventilation; attempt extubation to nasal intermittent positive pressure ventilation (NIPPV) or nasal continuous positive airways pressure (NCPAP) in the first PN week.

- Evolving phase: Use noninvasive ventilation with blood gas targets pH 7.25–7.35, PaO₂ 50–70 mm Hg, PaCO₂ 50–65 mm Hg.
- Established phase: Use noninvasive ventilation with blood gas targets pH 7.35–7.45, PaO₂ 60–80 mm Hg, PaCO₂ 45–60 mm Hg.

GENERAL MEASURES

Fluids/Nutrition

- Early phase: Restricting fluids to ~140 cc/kg/day may decrease BPD.
- Early/evolving/established phase: Aim to achieve 120–140 kcal/kg/day.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Multidisciplinary approach with primary care physician, pediatric pulmonologist, pediatric cardiologist, nutritionist, and speech, respiratory, occupational, and physical therapists as well as social worker is recommended.
- Monitor linear growth and nutritional status.
- Immunization: prophylaxis against respiratory syncytial virus (palivizumab injections once a month from October to April) and influenza
- Neurodevelopmental follow-up

PROGNOSIS

- Infants with BPD have high rates of rehospitalization in the first year of life (up to 50%).
- Long-term pulmonary sequelae that may persist into adulthood include airway obstruction, airway hyperreactivity, and concern regarding

development of chronic pulmonary obstructive disease (COPD) with aging.

- Long-term neurodevelopmental sequelae associated with BPD is not a specific neuropsychological impairment but more of a global deficit.
- Noninvasive ventilation approaches (NIPPV and NCPAP) hold promise in decreasing BPD.

COMPLICATIONS

- Prolonged intubation may lead to subglottic stenosis, tracheobronchomalacia.
- PH may result in cor pulmonale.

CODES

ICD10

P27.1 Bronchopulmonary dysplasia origin in the perinatal period

FAQ

- Q: Can my patient with BPD receive influenza vaccine?
- A: Yes. Influenza vaccination should be considered for babies older

than 6 months of age and their contacts.

- Q: The AAP Committee on Infectious Diseases recommends monthly immunoprophylaxis for infants with BPD who are <2 years old and have been on medical therapy for 6 months prior to onset of second respiratory syncytial viral season. What should I do if my patient turns 2 years old, 2 months after the respiratory season started?
- A: Once initiated, immunoprophylaxis should be completed even if the child turns 2 years old before the respiratory season has ended.
- Q: If my patient gets respiratory syncytial virus infection while on immunoprophylaxis (palivizumab; Synagis), should the monthly injections be stopped?
- A: Monthly prophylaxis with palivizumab should be discontinued because of extremely low likelihood of a second RSV hospitalization in the same season based on the revised AAP 2014 policy statement.
- Q: Will my patient with BPD continue to have respiratory problems?
- A: Survivors of BPD are more likely to be rehospitalized with respiratory illnesses in the first 2 years of their life, but the rate of hospitalization decreases after 2 years of age and is rare after 14 years of age. They are more likely to develop asthma, have abnormal pulmonary function tests, and require respiratory medications as compared to their peers. There is also some concern that survivors may develop a COPD phenotype as they age.
- Q: If my patient with BPD has recurrent croup, should I refer the patient to a pediatric pulmonologist for evaluation of asthma?
- A: Survivors of BPD are more likely to develop asthma as compared to peers born full term. However, upper and large airway problems such as subglottic stenosis and tracheomalacia are common in this population. Recurrent croup may result from a narrowing of the upper airway and hence, referral to a pediatric otolaryngologist should be considered to rule out causes such as subglottic stenosis.
- Q: Will my patient with BPD likely to have neurodevelopmental issues as well?
- A: Yes. Children with BPD are more likely to have delayed speech and language development, visual-motor integration impairments, and behavior problems. They may also have low average IQ, memory and

learning deficits, and attention problems.

BRUISING

Julie W. Stern

BASICS

DESCRIPTION

- Bruises are the result of extravasation of blood into the skin. Conventional usage often groups petechiae and bruises (or ecchymoses) together as purpura and defines them as follows:
 - Petechiae: flat, red, or reddish purple; 1–3 mm; nonblanching
 - Ecchymoses: larger than petechiae, local extravasation, nonpulsatile, sometimes palpable, color depends on age of lesion

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Congenital/anatomic
 - Coagulation factor abnormality: hemophilia, von Willebrand disease
 - Platelet defect: Bernard-Soulier syndrome, Glanzmann thrombasthenia, and storage pool defects
 - Congenital alloimmune or isoimmune thrombocytopenia
 - Neonatal extramedullary hematopoiesis
 - Hereditary hemorrhagic telangiectasia
- Infectious
 - Meningococcemia
 - Viral infections (coxsackievirus, echovirus)
 - Rocky Mountain spotted fever
 - Syphilis
 - Pertussis—secondary to severe cough
 - Septic or fat emboli
 - Disseminated intravascular coagulation—acquired factor deficiency
- Toxic, environmental, drugs
 - Warfarin—acquired factor deficiency

- Corticosteroids—striae caused by increased capillary fragility
- Aspirin and ibuprofen—cause a qualitative platelet abnormality
- Sulfonamides
- Bismuth
- Chloramphenicol
- Trauma
 - Normal activity
 - Child abuse
 - Valsalva, crying, forceful coughing
 - Cupping or coin rubbing
 - Tight garments
- Tumor (quantitative platelet abnormality)
 - Bone marrow replacement—leukemia, myelofibrosis, or (rarely) metastatic solid tumors
- Genetic/metabolic
 - Uremia
 - Vitamin C deficiency
 - Vitamin K deficiency—owing to antibiotics, biliary atresia, malabsorption (acquired factor deficiency)
- Allergic/inflammatory/vasculitic
 - Henoch-Schönlein purpura
 - Bone marrow failure: aplastic anemia (including Fanconi, paroxysmal nocturnal hemoglobinuria)
 - Increased destruction: idiopathic thrombocytopenic purpura, Evans syndrome, lupus
 - Nephrotic syndrome
 - Collagen vascular disease
 - Ehlers-Danlos syndrome, other joint hypermobility syndromes
 - Snake bite (copperhead)
- Miscellaneous (disorders that simulate bruises)
 - Ataxia telangiectasia
 - Cherry angiomas
 - Kaposi sarcoma

DIAGNOSIS

General goal is to determine if the cause of the bruising is

thrombocytopenia, a coagulation disorder, or an extrinsic factor (such as trauma, infection).

- **Phase 1:** Determine if the history of bruising and/or petechiae is acute or chronic in onset and if there is known trauma versus spontaneous lesions (see [Table 1](#))

Table 1. How to estimate the age of bruises

1. New	Purple, dark red
2. 1–4 days	Dark blue to brown
3. 5–7 days	Greenish to yellow
4. >7 days	Yellow

- Acute onset of diffuse subcutaneous bleeding with bruises of different ages may indicate severe thrombocytopenia.
- Generally, children will not bruise or develop petechiae spontaneously until the platelet count is $<20,000/\text{mm}^3$.
- Idiopathic thrombocytopenic purpura, leukemia, aplastic anemia, and so forth, can cause this bleeding.
- A hematologist should be consulted because of the risk of potentially life-threatening bleeding.
- Chronic history of recurrent bleeding may indicate an inherited coagulation defect such as von Willebrand disease or hemophilia. Familial history may be positive, although von Willebrand disease often goes undiagnosed into adulthood if there has been no challenge such as surgery.
- Various bleeding scores available but not fully validated in pediatrics; may be helpful to direct history taking
- **Phase 2:** Perform screening tests for bleeding disorders to categorize the abnormality.
 - Platelet count to assess level of thrombocytopenia
 - PT/PTT: Prolongation of either one or both of these may aid in diagnosis of von Willebrand disease, coagulation factor deficiencies, liver disease, and vitamin K deficiency.
 - Testing for von Willebrand disease and platelet aggregation disorders generally need to be done by a hematologist for accuracy

and interpretation.

- Bleeding time and PFA-100: Both tests are controversial and rarely used in pediatrics.

HISTORY

- **Question:** Significant bruising in the neonatal period?
- Significance: May indicate neonatal thrombocytopenia, congenital infections, and sepsis with disseminated intravascular coagulation
- **Question:** Bleeding in the neonatal period?
- Significance: Hemophilia. Other inherited disorders of coagulation may not be diagnosed until a child is older; tend to be mild; may be uncovered with preoperative testing or postoperative bleeding complications. Idiopathic thrombocytopenic purpura may occur at any age.
- **Question:** Pattern of bruising?
- Significance: In a younger child, may indicate normal toddler activity, child abuse, or religious practices such as coining
- **Question:** Use of aspirin, ibuprofen, cough syrups with guaifenesin, and/or antihistamines?
- Significance: Platelet dysfunction; use of these drugs may also unmask an otherwise mild inherited bleeding disorder.
- **Question:** Ecchymosis or petechiae?
- Significance: Infections such as meningococcemia or viruses and collagen vascular diseases may present with these.
- **Question:** Familial history?
- Significance: Positive familial history of inherited disorders of coagulation factors or platelet aggregation may aid in directing the workup. Negative familial history does not rule out any of these disorders.

PHYSICAL EXAM

- **Finding:** Good appearance, with a history of an antecedent viral illness?
- Significance: Those with idiopathic thrombocytopenic purpura often appear well, although often with a history of an antecedent viral illness.

- **Finding:** Ill appearance?
- **Significance:** It should raise concerns about malignancy, infection (especially meningococemia), or other acquired coagulation factor deficiencies such as those seen with liver failure.
- **Finding:** Bruising in unusual locations (back, genitalia, thorax)?
- **Significance:** Should raise suspicions of child abuse, especially if lesions are in different stages of healing or suggest the pattern of a hand or belt
- **Finding:** Purpura confined mostly to the legs?
- **Significance:** Typical of Henoch-Schönlein purpura

ALERT

- The amount of bruising may not correlate with the amount of internal bleeding that has occurred.
 - Hemophiliacs can significantly drop their hemoglobin during a thigh or psoas bleed without having much in the way of ecchymosis.
 - A child presenting with idiopathic thrombocytopenic purpura may have bruises and petechiae from head to toe without changing the hemoglobin much at all.
- **Finding:** Multiple ecchymoses in the pretibial regions?
- **Significance:** This is typical of normal toddler activity.
- **Finding:** Petechiae entirely above the nipple line?
- **Significance:** Consistent with Valsalva maneuver, severe cough, and viral infections
- **Finding:** Deeper bleeding in muscles and joints?
- **Significance:** Hemophilia
- **Finding:** Bleeding in mucous membranes?
- **Significance:** Severe thrombocytopenia, streptococcal pharyngitis, varicella, measles, and other viral infections can cause this.
- **Finding:** Gingival and/or mucous membrane bleeding?
- **Significance:** Von Willebrand disease can present with this. Severe thrombocytopenia and ITP may also present with oral bleeding.
- **Finding:** Involvement of the reticuloendothelial system?
- **Significance:** Can be found with malignancies such as leukemia or with viral or bacterial infections, indicated by hepatosplenomegaly or

lymphadenopathy

- **Finding:** Upper extremity limb malformations and bruising?
- **Significance:** May present with syndromes such as Fanconi anemia and thrombocytopenia absent radii (TAR)

ALERT

Factors that make this an emergency include the following:

- Severe thrombocytopenia below 10,000–20,000/mm³ carries a higher risk of spontaneous internal bleeding including intracranial bleeding.
- Bleeding or bruising accompanied by evidence of leukemia or other malignancy
- Evidence of sepsis (disseminated intravascular coagulation) or meningococemia

DIAGNOSTIC TESTS & INTERPRETATION

- **Test:** CBC
- **Significance:** Platelet count is the most important; abnormalities of WBC or Hgb may aid in diagnosis of bone marrow infiltration or failure.
- **Test:** PT
- **Significance:** Elevation may indicate warfarin ingestion or factor VII and/or vitamin K deficiencies.
- **Test:** aPTT
- **Significance:** Prolongation is seen with hemophilia and may be seen in von Willebrand disease.
- **Test:** Both PT and PTT
- **Significance:** Both are prolonged in disseminated intravascular coagulation, liver failure, and severe vitamin K deficiency.
- **Test:** Bleeding time
- **Significance:** Lengthened in platelet aggregation disorders and with drug effects
- **Test:** Fibrinogen
- **Significance:** Decreased in liver failure, disseminated intravascular coagulation
- **Test:** Urinalysis
- **Significance:** Hematuria and/or proteinuria may indicate Henoch-

Schönlein purpura, nephrotic syndrome, or other vasculitis.

TREATMENT

GENERAL MEASURES

- Thrombocytopenia precautions for platelets $<20,000$ – $50,000$ —toddlers may need a helmet until platelet count recovers; patients with hemophilia may need restricted activity, generally not needed for patients with von Willebrand disease. Depends on underlying cause.
- Factor replacement for hemophilia
- Platelet transfusion for thrombocytopenia due to decreased production
- IVIG, steroids, Rh immune globulin, thrombopoietin (TPO) mimetics for ITP

ISSUES FOR REFERRAL

- Outpatient evaluation for bruising without significant thrombocytopenia, family history of bleeding disorder
- Suspected child abuse

Admission Criteria

Severe thrombocytopenia, suspected child abuse, significant bleeding, significant head trauma

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

Recurrent and chronic ITP possible

COMPLICATIONS

Significant bleeding with a bleeding disorder, thrombocytopenia

CODES

ICD10

- T14.8 Other injury of unspecified body region
- R23.3 Spontaneous ecchymoses
- D68.9 Coagulation defect, unspecified

FAQ

- Q: Is hemophilia always diagnosed in the newborn period?
- A: No. A familial history may provide clues, but a significant number of patients represent a spontaneous mutation. Additionally, not all boys with hemophilia will bleed with circumcision, and the diagnosis may not be made until the infants become more active.
- Q: What is a common cause of bruising among girls?
- A: Girls may first come to attention at menarche and be diagnosed at

that time with von Willebrand disease. Rarely, girls whose fathers have hemophilia may be unfavorably lyonized and, therefore, have decreased factor levels consistent with mild hemophilia.

- Q: Can boys with a family history of von Willebrand disease be circumcised?
- A: Yes, but only within the first few days of life and testing does not need to be completed prior to procedure. If procedure is not completed in the neonatal period, testing may need to be delayed until 6 months of life or later.

BRUXISM

Anupama R. Tate • Karen R. Fratantoni

BASICS

DESCRIPTION

- Bruxism is defined as habitual nonfunctional forceful contact of teeth, which is involuntary. These movements can include excessive grinding, clenching, or rubbing of teeth.
- Other nonfunctional (or “parafunctional”) oral habits include movements not involved with normal chewing, swallowing, or speaking, such as chewing pencils, nails, cheek, or lip.
- Sleep bruxism should be distinguished from daytime awake bruxism.
- Awake bruxism is rare with little or no audible sound during clenching, compared to the loud grinding sound commonly occurring in sleep bruxism.

EPIDEMIOLOGY

- May occur throughout life but frequently tends to peak in early childhood, then decreases with age
- Infants have been known to grind their teeth during the eruption of primary teeth.
- May be temporarily or intermittently present, which makes diagnosis difficult
- Recent systematic review of literature reported no gender differences in prevalence. Previous studies suggested girls may be more affected than boys.
- Some studies support higher incidence in children with developmental disabilities, Down syndrome, sleep disorders, and autism.
- No genetic mechanism has been explained. Based on self-reports, 20–50% of children with sleep bruxism have an immediate family member who experienced bruxism as a child.

Prevalence

In children, prevalence in the literature is highly variable with a range of

4–40%. Prevalence decreases with increasing age. Sleep bruxism progressively diminishes around 9–10 years of age.

ETIOLOGY

The exact cause is not known. It is likely to be a multifactorial process including pathophysiologic, psychologic, or morphologic factors.

- Awake bruxism is more commonly associated with psychosocial factors and psychopathologic symptoms.
- Dental factors (current evidence suggests that they play a small role, only ~10% of cases)
 - Occlusal interferences, including malocclusions, in which teeth do not interdigitate smoothly
 - High dental restorations (e.g., fillings or crowns)
 - Intraoral irritation (e.g., sharp tooth cusp)
 - Teething
- Psychological factors
 - Nervous tension (related to stress, anger, and aggression)
 - Personality disorders
 - Posttraumatic stress disorder
- Common systemic factors
 - Moving between levels of sleep
 - Sleep-disordered breathing
 - Snoring and sleep apnea
 - Tonsil/adenoid hypertrophy
 - Neurodevelopmental disorders (e.g., cerebral palsy)
 - Brain injury
 - ADHD
- Other possible factors
 - Asthma
 - Allergies
 - Nasal obstruction
 - Exposure to secondhand smoke
 - Medications (amphetamines, antidepressants—particularly serotonin reuptake inhibitors)

DIAGNOSIS

- Teeth
 - Wearing of facets, abraded areas
 - Extreme wear of primary teeth is occasionally observed; however, pulp or nerve damage is rare.
 - Broken dental restorations
 - Loose teeth
 - Progression of periodontal disease (gingival inflammation, recession, and alveolar bone loss)
 - Pain or sensitivity
- Muscular symptoms of the head and neck muscles, most often seen in the lateral pterygoids followed by the medial pterygoids and masseters
 - Pain
 - Trismus
 - Spasm
- Frequent headache or migraines
- Parasomnias
- Temporomandibular joint (TMJ) disorders
 - Symptoms (pain, clicking, popping when opening or closing)
 - Limited mandibular range of motion

DIFFERENTIAL DIAGNOSIS

- Dental erosion
- Drug reaction
- Gastroesophageal reflux
- Seizures
- Sleep disorder
- Stress

TREATMENT

MEDICATION

- Analgesics or anti-inflammatory medications (e.g., ibuprofen) for management of symptoms

- Rarely used
 - Muscle relaxants for symptoms
 - Mild anxiolytics if anxiety plays an etiologic role

GENERAL MEASURES

- Often, children outgrow bruxism and no treatment is indicated.
- When treatment is needed, it is best managed in a multiprofessional team approach including a dentist.
- Patient and family education: Ensure that the bruxism itself does not become an issue, generating increased stress for the child.
- Plastic or vinyl bite guard (must not interfere with normal dental growth and development)
- Stress counseling
 - Identify and address sources of stress.
 - Meditation
 - Music therapy
 - Biofeedback exercises
 - Acupressure and/or acupuncture
- Counseling/psychotherapy
 - Hypnosis

Additional Therapies

- Rarely used
 - Occlusal adjustment (selective tooth grinding to balance the bite):
There is no evidence-based support. Because of inadequate data regarding their usefulness, irreversible therapies should be avoided.
 - Tonsillectomy and adenoidectomy

COMPLEMENTARY & ALTERNATIVE THERAPIES

- Warm compresses for muscle or TMJ symptoms
- Limiting affected muscle activity (e.g., “do not open wide,” “take small bites,” “avoid chewing gum”) may help reduce TMJ symptoms.

INPATIENT CONSIDERATIONS

- Treatment for bruxism is rarely indicated for children in the inpatient setting.
- Therapy is justified if damage to the permanent dentition or periodontal

structures is observed.

- For neurologically impaired patients with acute self-injurious issues, bite blocks or mouth props can be protective. Patients who exhibit chronic chewing may require the fabrication of custom-fitted mouth guards, which may require the use of deep sedation or general anesthetic procedures to construct the appliance. The risk of these procedures would need to be weighed against the benefit of the bite guard.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

The large majority of bruxism in children stops without any therapy. Monitor for significant associated problems; recommend treatment if damage to permanent dentition and/or periodontal structures occurs.

PROGNOSIS

- There are no data to indicate a cause-and-effect relationship exists for bruxism in childhood continuing into adulthood.
- Preschool- and school-age children
 - Ensure that all children establish a dental home by 1 year of age.
 - Typically ceases without therapeutic intervention
 - Associated problems are rare.
 - Monitor for associated conditions.
- Adolescents
 - More commonly benefit from therapeutic intervention
 - Associated problems (e.g., attrition of teeth; muscular, TMJ symptoms) may also require therapy.
- Special-needs children
 - Long-term prognosis is poor.
 - Children who are comatose or those who have suffered traumatic brain injuries or neurologically impaired may be managed by the use of prefabricated bite blocks or, in rare cases, by the fabrication of custom-fitted mouth guards to minimize risk of damage to lips or

tongue. Intraoral botulinum-A injections have relieved the spasticity.

FAQ

- Q: What is the recommendation for nighttime bruxism management in a preschool child?
- A: The majority of bruxism in children stops without any therapy. Considering the controversial nature of treatment modalities, it is prudent to advise no treatment for childhood bruxism and to advise the parents that the condition is common and the child will outgrow the condition.
- Q: Does bruxism in a child result in problems with the permanent teeth or with the TMJ?
- A: There is no evidence that bruxism in children leads to problems during adolescence or later.
- Q: What is the recommendation for bruxism management in a child with snoring or tonsil/adenoid hypertrophy?
- A: Studies have shown a higher incidence of bruxism among children with tonsil hypertrophy and sleep apnea and a decrease in bruxism after adenotonsillectomy. Bruxism alone, without evidence of upper airway obstruction, would not currently be an indication for adenotonsillectomy. Physicians should assess children with bruxism for upper airway obstruction and refer when indicated.

BULIMIA

Sara F. Forman • Melissa B. Freizinger

BASICS

DESCRIPTION

Bulimia nervosa is an eating disorder characterized by the following:

- Recurrent binge eating episodes characterized by rapid consumption of large amounts of food in discrete periods of time, usually <2 hours
- Feeling of lack of control over eating behavior during eating binges
- Compensatory behavior such as self-induced vomiting, laxative or diuretic use, strict dieting, or vigorous exercise to induce weight loss
- Minimum average of one binge eating/compensatory behavior episode per week for at least 3 months
- Associated feelings of guilt, shame, low self-esteem, and depression
- Persistent overconcern with body shape and weight
- Symptoms and psychopathology may overlap with anorexia nervosa but does not occur exclusively during episodes of anorexia nervosa.

EPIDEMIOLOGY

- Onset in adolescence to young adulthood
- Approximately 10:1 female-to-male ratio
- 70% of the adolescents who meet criteria for full and partial syndrome eating disorders also met criteria for an Axis I disorder.

Prevalence

- Adolescents have a 1–1.5% 12-month prevalence of bulimia according to the Diagnostic and Statistical Manual of Mental Disorders 5th edition (DSM-5).
- 25% of college-aged women use bingeing and purging as a weight management technique.
- Bulimia nervosa prevalence rates in Western countries for females range from 0.3% to 7.3%.

RISK FACTORS

Genetics

Recent studies, including twin studies, suggest that bulimia nervosa and binge eating may have a genetic vulnerability and familial transmission.

GENERAL PREVENTION

- Emphasize healthy self-esteem/body image with preadolescents and adolescents
- Regular family dinners may have some protective effect against eating disorders.

ETIOLOGY

- Personality traits of low self-esteem, self-regulatory difficulties, frustration, intolerance, and impaired ability to recognize and express feelings directly described in bulimia nervosa
- Small positive association between childhood sexual abuse and eating disorders, but size and nature of this association not known
- Neuroendocrine abnormalities may also play a role: Abnormalities in serotonergic and vagal function have been demonstrated in patients with bulimia nervosa.
- Cholecystokinin response to a meal is decreased in bulimia nervosa, which may also indicate abnormal satiety signaling
- May be abnormalities in other hormones or neurotransmitters such as leptin, dopamine, and endorphins. Unclear if cause or effect.

COMMONLY ASSOCIATED CONDITIONS

- Lifetime rates of major depressive disorder in individuals with eating disorders 50–75%
- In adolescents, bulimia is associated with dysthymia more than major depression.
- 63.5% of bulimic patients have lifetime history of an anxiety disorder.

DIAGNOSIS

HISTORY

- Eating disorder specific
 - Eating habits
 - Presence of binge or purge behavior

- Food rituals
- Body image
- Exercise history
- Actual and desired weights, minimum and maximum weights
- Use of laxatives, diuretics, diet pills, emetics, ipecac, or weight loss supplements
- Menstrual history—amenorrhea or oligomenorrhea
- Unease with others watching them eat
- Preoccupation with food/eating
- Preoccupation with body weight/shape
- Fear of loss of control over one's body
- General
 - Weakness or fatigue or hyperactivity
 - Thirst, frequent urination
 - Headaches
 - Dizziness
 - Abdominal pain, fullness, or bloating; nausea
 - Constipation or diarrhea
 - Dental caries
 - Irregular menses
- Psychiatric
 - Mood disorder
 - Substance abuse
 - Anxiety
 - Personality disorders
 - Suicidal thoughts
 - Low self-esteem
 - Impulsivity
- Family
 - Medical and psychiatric histories
- Specific questions
 - Do you have a weight goal?
 - How do you control your weight?
 - How do you feel about yourself?
 - Do you ever vomit, use diuretics, or laxatives? If so, how often?

PHYSICAL EXAM

- Vital signs: Check for hypotension, orthostasis, and hypothermia.
- Weight: may be normal, overweight, or underweight
- Erosion of dental enamel: exposure to gastric acid secondary to frequent vomiting
- Parotid gland enlargement due to vomiting
- Calluses on knuckle or hands: Russell sign secondary to inducing vomiting
- Muscle weakness or cramps: electrolyte disturbance

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Part of the diagnostic workup. Most useful for assessing complications; no diagnostic or confirmatory laboratory test for bulimia nervosa. Many patients have normal labs.
- CBC: iron deficiency anemia
- Electrolytes, including calcium, magnesium, and phosphate: Abnormalities may occur as a result of prolonged vomiting or laxative use. Most common pattern for vomiting is hypokalemic-hypochloremic alkalosis.
- BUN and creatinine: Renal function usually normal, but BUN may be elevated secondary to dehydration or altered intake
- Glucose: patient may be hypoglycemic
- Cholesterol, lipids: may be elevated in starvation state
- Amylase: increased secondary to vomiting
- Lipase: increases may indicate severe complications such as pancreatitis
- Total protein, albumin, prealbumin: usually normal, but may be low if with malnutrition
- Liver function tests: Transaminases may be mildly elevated from starvation.
- Erythrocyte sedimentation rate (ESR): almost invariably normal; if elevated, consider occult organic process
- Bicarbonate level: metabolic alkalosis from vomiting or metabolic acidosis if using laxatives or dehydrated
- Urine toxicology screen (optional): may be positive as this disorder

often is associated with substance abuse

Imaging

- Electrocardiogram with rhythm strip: may see U waves with hypokalemia, check QTc
- Consider upper GI series with small bowel follow-through if unclear etiology of vomiting
- Consider dual-energy x-ray absorptiometry (DEXA) scan if prolonged amenorrhea to evaluate bone mineral density.

Diagnostic Procedures/Other

Eating disorder questionnaires: Questionnaire assessments may be helpful and augment the diagnostic interview in diagnosing bulimia nervosa.

DIFFERENTIAL DIAGNOSIS

- Psychogenic vomiting
- Drug abuse
- GI obstruction
- Hiatal hernia
- Achalasia, gastroesophageal reflux
- Brain tumor

TREATMENT

MEDICATIONS

- Antidepressants
 - Decrease the binge–purge behavior
 - Improve attitudes about eating
 - Lessen preoccupation with food and weight
 - Fluoxetine (Prozac), sertraline (Zoloft), desipramine, citalopram, and fluvoxamine (Luvox) used with good results
 - Antidepressant effect may diminish over time; may relapse when drug stopped
 - Psychotherapy and cognitive behavioral therapy combined with antidepressant therapy appears to have the best outcome.
 - Low response rate to alternative treatments after cognitive behavioral therapy and 1st-line antidepressant therapy

- Few studies either of medication or psychotherapy in those <18 years of age; however, cognitive behavioral therapy and family-based therapy appear promising
- Stool softeners: Often of little use for constipation; consider nonstimulating osmotic laxatives if severe
- Ondansetron: Shown in 1 study to decrease vomiting frequency; may help normalize the physiologic mechanism controlling satiation.

ADDITIONAL TREATMENT

- Cognitive behavioral therapy (CBT) with family involvement effective
 - Can be done in group or individual formats
 - More effective than interpersonal psychotherapy or behavioral therapy alone
 - Helps patients determine other ways to cope with the feelings that precipitate purging and to try to correct maladaptive thoughts and beliefs about body image
 - May also be effective in a self-help format, including self-help manual format
 - One study of CBT in adolescents showed considerable promise.
- Family-based treatment (FBT): Therapist empowers parents to disrupt behaviors such as binge eating, purging, restrictive eating, and other compensatory behaviors. The treatment has shown positive research outcomes.
- Individual interpersonal psychotherapy (IPT) is helpful but takes longer to have an effect.
- Dialectical behavioral therapy (DBT): Skill-based treatment shown to be helpful for adult patients with binge eating disorder and less severe symptoms of bulimia nervosa.
- Family therapy
- Group therapy
- Outpatient supportive psychotherapy

ADDITIONAL THERAPIES

Physical activity shown in one study to reduce pursuit of thinness and decrease bingeing/purging behavior. Both physical activity and yoga have shown promise as adjunct treatments.

INPATIENT CONSIDERATIONS

Initial Stabilization

Hospitalize in cases of the following:

- Dehydration
- Severe electrolyte disturbances
- Intractable vomiting
- Acute psychiatric emergencies (e.g., suicidal ideation, acute psychosis)
- Medical complication of malnutrition (e.g., aspiration pneumonia, cardiac failure, pancreatitis, Mallory-Weiss syndrome)
- Comorbid diagnosis that interferes with the treatment of the eating disorder (e.g., severe depression, obsessive-compulsive disorder, severe family dysfunction)
- Failure of outpatient therapy

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Reduction in binge and purge episodes may take time.
- Behavioral and thought disorders associated with bulimia nervosa may be of long duration.

Patient Monitoring

Signs to watch for:

- Weight loss or major weight fluctuations
- Electrolyte abnormalities
- Muscle cramps
- Fatigue
- Depression or mood disturbance
- Mood swings/irritability
- Increasing emotional lability
- Menstrual function/irregular menses

PROGNOSIS

Eating disorders have the highest mortality rate of any mental disorder. Reported mortality rates vary between studies. Part of the variance is because those with an eating disorder may ultimately die of heart failure,

organ failure, malnutrition, or suicide. Crude mortality rates reported in 2009 were the following:

- 4% for anorexia nervosa
- 3.9% for bulimia nervosa
- 5.2% for eating disorder not otherwise specified
- Most patients have episodic course with trend toward improvement.
- No studies of long-term prognosis in adolescents
- Adult studies: 5- to 10-year follow-up
 - Up to 85% of patients achieve recovery from bulimia nervosa in various studies.
- Poor prognostic indicators: concomitant depression, personality disorder, substance abuse, frequent vomiting
- Good prognostic indicators
 - High motivation for treatment
 - No concurrent disruptive psychopathology
 - Good self-esteem

COMPLICATIONS

- Pulmonary
 - Aspiration pneumonia
 - Pneumomediastinum
- GI
 - Pancreatitis
 - Parotid or salivary gland enlargement
 - Gastric and esophageal irritation and gastroesophageal reflux
 - Mallory-Weiss tears
 - Paralytic ileus (from laxative abuse/hypokalemia)
 - Severe constipation (due to laxative abuse and subsequent dependence)
- Metabolic
 - Hypokalemia (due to laxative abuse/emesis)
 - Secondary cardiac dysrhythmias, myopathy
 - Electrolyte imbalances, including hypomagnesemia; acid–base disturbances
 - Fluid imbalances
 - Hyperamylasemia

- Edema (secondary to hypoproteinemia or renal sodium and water retention secondary to hypovolemia and secondary hyperaldosteronism)
- Bone loss (if amenorrhea; significantly more common in anorexia nervosa)
- Dental
 - Enamel erosion
 - Caries and periodontal disease
- Hormonal
 - Irregular menstrual bleeding

- F50.9 Eating disorder, unspecified

FAQ

- Q: How do I determine if a patient has anorexia with vomiting or bulimia?
- A: The key feature of anorexia nervosa that distinguishes it from bulimia nervosa is the degree of malnutrition and presence of bingeing. There is a definite crossover between patients with anorexia nervosa and bulimia nervosa. If bingeing and purging is seen in the setting of significant malnutrition and low weight, the patient is diagnosed with anorexia nervosa.
- Q: What laboratory abnormalities should I look for in my patients with bulimia?
- A: Electrolyte abnormalities, particularly hypokalemia. Patients may develop a hypochloremic metabolic alkalosis. If electrolytes are significantly abnormal, hospitalize until normalized.

C1 ESTERASE INHIBITOR DEFICIENCY

Judith Kelsen

BASICS

DESCRIPTION

- A hereditary and acquired form of recurrent angioedema. The attacks are usually without urticaria.
- Has been classified into a number of types, including
 - Hereditary angioedema (HAE) type I (transmitted as autosomal dominant)
 - HAE type II (transmitted as autosomal dominant)
 - Acquired angioedema (AAE) types I, II, III, and IV
- HAE type I
 - Accounts for ~85% of the C1 esterase deficiencies, insufficient levels of normal C1-esterase inhibitor (C1-INH) protein due to a genetic alteration that leads to impairment of messenger RNA (mRNA) transcription or translation and therefore decreased enzyme synthesis. Often thought of as quantitative deficiency.
- HAE type II
 - Patients have normal levels of less functional C1-INH. May be thought of as a qualitative deficiency.
- HAE type III
 - An estrogen-dependent form; typical clinical features of type I with normal C1-INH level and function and normal C4
 - These cases are all female and have dominant mode of inheritance; poorly understood mechanism.
- In acquired deficiency of C1-INH, there appears to be a normal ability to synthesize the enzyme; however, the enzyme is metabolized at an increased rate. This syndrome may be seen in patients with autoimmune diseases or malignancy and usually occurs after the 4th decade of life.
- AAE type I
 - Very rare syndrome usually associated with lymphoproliferative

(usually B-cell) carcinomas, autoimmune diseases, and paraproteinemias. Because of the other disease processes, complement-activating factors and idiotype–anti-idiotype complexes act to increase consumption of C1-INH.

- AAE type II
 - Develops when an autoantibody is produced against the C1-INH protein. When these antibodies adhere to the C1-INH molecule, conformational change occurs, leading to decreased function or enhanced metabolism. This type is often associated with autoimmune disorders.
- AAE type III
 - Associated with sex hormones (specifically in pregnancy)
- AAE type IV
 - Drug-induced AAE, particularly associated with ACE inhibitors or angiotensin receptor blockers
- AAE forms may be differentiated from HAE by genetic studies and serologically by significantly decreased C1q, C1r, and C1s levels and decreased functional activity of the enzyme in AAE.

EPIDEMIOLOGY

Incidence

1:50,000

Genetics

HAE types I and II are transmitted as autosomal dominant.

PATHOPHYSIOLOGY

- C1-INH is a single-chain polypeptide with a molecular weight of 108 kD. The gene has been identified on chromosome 11 (11q12–q13.1). It is involved in the control of vascular permeability.
- C1-INH is a member of the serpin family of serine protease inhibitors produced in the liver.
- This protein inhibits the classic complement pathway by inhibiting activation of C2 and C4. In the fibrinolytic system, C1-INH inhibits formation of plasmin, the activation of C1r and C1s, and the formation of bradykinin from kininogen.
- Deficiency of this enzyme results in activation of the classic

complement system along with fibrinolysis and kinin formation, which is felt to participate in the production of angioedema.

- Kinin is known to cause similar histologic lesions to histamine but without pruritus.
- The complement activation leads to production of C2b, a product that also has kinin-like activity, and bradykinin, a vasoactive peptide that may also participate in the formation of angioedema.

DIAGNOSIS

HISTORY

- Presentation: Patients with HAE usually present in the 2nd decade of life with angioedema involving the subcutaneous tissues (mostly involving the extremities).
- Attacks can be precipitated by trauma, infection, or pregnancy.
- Timing
 - Classically, the edema develops gradually over several hours and increases slowly over 12–36 hours.
- GI effects
 - Predominant symptom in 25% of patients
 - Patients may experience abdominal attacks with sudden and very severe onset without visible edema.
 - Angioedema involving the GI tract may lead to severe pain, vomiting, and diarrhea as well as ascites.
 - Secondary to transient edema of small bowel resulting in intestinal obstruction, ascites, and hemoconcentration
- Respiratory complications: 2 of 3 patients will have orofacial or laryngeal swelling.
- Hives: The edema usually occurs without evidence of inflammation; rash resembles urticaria (however, episodes of urticaria have also been documented).
- The variability of clinical manifestations, even among individuals with the same genetic mutation, is striking, implicating nongenetic factors or other genes as possible mediators of clinical presentation.
- Emesis

- Diarrhea
- Hypotension from extravasation of plasma into the skin
- Hemoconcentration
- Azotemia
- CNS complaints, including headache, hemiparesis, and seizures, may be triggered by trauma or stress.
- AAE presents similarly, in the same way but usually in the 4th decade of life; not associated with a familial history.

PHYSICAL EXAM

Depending on the clinical features, angioedema causes pale, well-demarcated, tense, brawny, nonpruritic, and nonpitting single or multiple localized swellings. These may involve the periorbital tissues, genitalia, face, tongue, lips, larynx, extremities, and GI tract.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- C1-INH concentration
- C1-INH activity
- C4 concentration: low serum level
- C4D: cleavage product of C4, low even when C4 is normal
- C1q concentration (usually lower in patients with AAE)

DIFFERENTIAL DIAGNOSIS

- IgE mediated
 - Episodic angioedema
 - Allergic reactions to food and drugs
 - Physically induced angioedema
- Hypocomplementemic HAE
- Idiosyncratic
 - NSAIDs
 - Other drugs
- Lupus erythematosus
- Idiopathic

TREATMENT

GENERAL MEASURES

- During an acute episode, management focuses on adequate respiratory and fluid resuscitation and the treatment of pain.
- In HAE, acute attacks are treated with replacement of the C1-INH with IV concentrates. Fresh frozen plasma may also be used.
- Recent studies have shown benefit with recombinant human C1-INH for acute attacks and prophylaxis.
- A recent study has demonstrated that the time to onset of symptom relief is an appropriate end point for assessing the efficacy of C1-INH therapy.
- For prophylaxis, androgens (such as danazol and stanozolol) are used in postpubertal patients with HAE of both types. These androgens stimulate the synthesis of C1-INH, and although the level of activity is not normalized, it is increased sufficiently to be clinically efficacious.
- In prepubertal children, androgens are used only in those with severe attacks; purified C1-INH can be used if available. Antifibrinolytics should be used in prepubertal children over androgens.
- Patients should avoid estrogen oral contraceptive pills (OCPs) or use with caution.
- For patients who do not tolerate androgens, tranexamic acid and ϵ -aminocaproic acid (antifibrinolytic inhibitors of plasmin activity) may be used, although they carry the risk of significant side effects.
- AAE type I patients may respond to epinephrine for reversal of airway compromise.
- AAE type I requires an intensive search for malignancy, although this form of AAE occasionally appears before the development of clinical signs of the malignancy.
- Androgens are also effective in preventing attacks in individuals with this syndrome.
- AAE type II requires immunosuppression to decrease formation of the autoantibody.
- These patients may respond to C1-INH concentrate.
- Androgen treatment has not led to good clinical response.
- Prophylaxis prior to dental procedures or surgery: high-dose danazol
- Potential treatment: plasma kallikrein antagonists, bradykinin

antagonists, serine protease inhibitors

- Genetic counseling: Given the autosomal dominant inheritance, family counseling is important.

INPATIENT CONSIDERATIONS

Initial Stabilization

Therapy is divided into management of the acute attack, maintenance therapy for HAE, and more specific interventions for those with AAE.

CODES

ICD10

D84.1 Defects in the complement system

FAQ

- Q: What are other causes of angioedema?
- A:
 - Classic allergic reactions to food and drugs
 - Physically induced angioedema
 - IgE-mediated episodic angioedema
 - Idiosyncratic reactions to nonsteroidal anti-inflammatory and other drugs
 - Lupus erythematosus
 - Idiopathic causes
- Q: What are the usual precipitating factors in causing reactions?
- A: Recurrent episodes of angioedema, abdominal pain, nausea, and vomiting that occur spontaneously or after local trauma, especially to the upper respiratory tract:
 - Vigorous exercise
 - Emotional stress
 - Menstruation

CAMPYLOBACTER INFECTIONS

Matthew P. Kronman

BASICS

DESCRIPTION

- Campylobacter species are motile, curved, gram-negative bacilli that are commensal flora of birds, pigs, and cattle and commonly cause bacterial gastroenteritis in humans.

EPIDEMIOLOGY

- Campylobacter infections are among the most common causes of enteritis worldwide, with the highest attack rates in children <4 years.
- Asymptomatic infection occurs in 30–100% of chickens, turkeys, and water fowl. Other reservoirs of infection include swine, cattle, sheep, horses, rodents, and household pets (especially young pets).
- Contaminated water and unpasteurized milk are other sources of infection.
- Infections typically occur sporadically, without outbreaks.

Incidence

- Estimated rates of Campylobacter infection vary widely worldwide. In the United States, the estimated annual incidence in 2012 was 14.3/100,000 overall, 14% higher than in 2006–2008 (95% CI, 7–21%).
- The highest U.S. incidence is for those <5 years at 24.08/100,000 population.
- Among speciated U.S. infections, 90% were *C. jejuni* and 8% were *C. coli*. Of all U.S. infections, 15% resulted in hospitalization and 0.1% in death.
- The incidence is seasonal and generally peaks in summer worldwide.

Prevalence

- Although surveillance data are limited, the highest prevalence of Campylobacter infections occur in resource-poor settings.
- Campylobacter is the most common cause of travelers' diarrhea in

Southeast Asia, accounting for a third of all infections.

RISK FACTORS

- Approximately 40% of *Campylobacter* enteritis is estimated to be attributable to undercooked chicken consumption, which had an odds ratio (OR) of 3.4 (95% CI, 2.2–4.5) for infection.
- Other risk factors for *Campylobacter* enteritis include international travel (OR 4.9, 95% CI, 2.9–8.2), direct contact with farm animals (OR 2.6, 95% CI, 2.0–3.4), chronic disease, poor food preparation hygiene, consumption of chicken prepared outside the home, and use of acid-suppressive medications.
- Children are at higher risk relative to adults.
- Frequent exposure to *Campylobacter* (e.g., among food handlers and abattoir workers) may protect against disease.
- Person-to-person transmission of *C. jejuni* has been reported when index cases were young children incontinent of feces or as vertical transmission from mother to neonate.
- Asymptomatic hospital personnel or food handlers have not been implicated as sources.

GENERAL PREVENTION

- Hand washing after contact with animals or animal products, cleaning cooking utensils and cutting boards after contact with raw poultry, proper cooling and storage of foods, pasteurization of milk, and chlorination of water supplies decrease the risk for infection.
- Diapered infants with symptomatic infection should be excluded from child care until resolution of diarrhea.
- No licensed vaccines currently exist, but *C. jejuni* strains with decreased risk of secondary Guillain-Barré syndrome (GBS) are being developed as candidates for capsular polysaccharide conjugate vaccines.

PATHOPHYSIOLOGY

- Transmission of disease is by the fecal–oral route from contaminated food and water or by direct contact with fecal material from animals or persons infected with the organism.
- As few as 500 organisms may be required to produce infection.

- *Campylobacter* spp. possess 1 or 2 flagella that provide the organism's motility and facilitate intestinal colonization.
- *C. jejuni* adheres to epithelial cells and mucus, secretes cytotoxins (which play a role in the development of watery diarrhea), can invade intestinal epithelial cells using a microtubule entry system, and induces an inflammatory ileocolitis.
- *Campylobacter* can cause a range of clinical manifestations, including enteritis and rare localized extraintestinal infections.
- Bacteremia, although uncommon, can occur, especially in the neonate and immunocompromised host; *C. fetus* is the species most likely to be isolated. *C. fetus* can also cause neonatal meningitis.
- *C. upsaliensis*, *C. lari*, and *C. hyointestinalis* have been identified in immunocompromised individuals and are usually associated with a self-limiting enteritis but can occasionally cause systemic illness.

ETIOLOGY

- *Campylobacter* is a motile, curved, microaerophilic, non-lactose-fermenting, oxidase-positive, gram-negative rod that requires oxygen and carbon dioxide for optimal growth.
- Three main *Campylobacter* species involved in human infections include *C. jejuni*, *C. coli* (which cause enteritis), and *C. fetus* (implicated in systemic illness in neonates and compromised hosts). Rarer human pathogens include *C. concisus*, *C. curvus*, *C. hyointestinalis*, *C. lari*, *C. rectus*, *C. sputorum*, and *C. upsaliensis*.

COMMONLY ASSOCIATED CONDITIONS

Campylobacteriosis occurs in both healthy and immunocompromised individuals.

DIAGNOSIS

HISTORY

- Enteritis is characterized by fever, abdominal pain, and bloody diarrhea.
- Symptoms can last for 24 hours and be indistinguishable from viral gastroenteritis or appendicitis, or can be relapsing, thus mimicking

inflammatory bowel disease.

- In some patients, illness can be severe, resembling dysentery.
- Incubation period is usually 2–5 days and is usually self-limited by 5–7 days.

PHYSICAL EXAM

- Abdominal pain, diarrhea, malaise, and fever are common signs and symptoms of infection.
- Stools can contain occult or visible blood.
- Inflammatory ileocolitis is the most common manifestation in children.
- If the infection establishes a chronic phase (20% of infected patients), symptoms may mimic inflammatory bowel disease and other immunoreactive complications may occur.

ALERT

Not all bacterial colitis presents with blood or mucus in the stool. Therefore, increased suspicion for bacterial colitis should exist if the diarrhea is prolonged or the patient has appropriate exposures.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Stool culture requires selective media (Skirrow, Butzler, or campy-BAP), microaerophilic conditions, and an incubation temperature of 42°C to isolate important *Campylobacter* species.
- *C. fetus*, *C. hyointestinalis*, and *C. upsaliensis* may not be detected on *Campylobacter*-selective media due to their sensitivity to antimicrobial agents in the media.

Imaging

Imaging is not often required for diagnosis.

Diagnostic Procedures/Other

- Rapid DNA-based testing to detect and differentiate *Campylobacter* spp. from other enteropathogens is being developed and has moderate sensitivity compared to the current gold standard of stool culture.

Pathologic Findings

- Examination of fecal specimen for darting motility of *C. jejuni* by darkfield or phase-contrast microscopy within 2 hours of passage can

permit presumptive diagnosis.

DIFFERENTIAL DIAGNOSIS

- Campylobacter infection should be considered in all patients with a diarrheal illness, especially those with blood or mucus in their stool, recurrent gastritis, or in immunocompromised hosts.
- Symptoms can overlap with those of appendicitis or inflammatory bowel disease.
- Additional intestinal bacterial pathogens include Aeromonas, Campylobacter, Clostridium difficile, Escherichia coli, Listeria, Plesiomonas, Salmonella, Shigella, Vibrio species, and Yersinia.
- Other viral and parasitic pathogens include amebiasis, adenovirus types 40 and 41, Cryptosporidium, Cyclospora, Cystoisospora, Giardia, norovirus, and rotavirus.

TREATMENT

MEDICATION

- Most patients have self-limited infection.
- Select patient populations (HIV and other immunocompromised individuals, pregnant women) may benefit from early therapy.
- If treated in the first 3 days of enteritis, erythromycin (for 5 days) or azithromycin (for 3 days) appear effective in eradicating the organism from the stool within 2–3 days and shortening the course of diarrhea.
- Ciprofloxacin, tetracycline, aminoglycosides, and imipenem are alternatives if resistant or bacteremic strains are present, although fluoroquinolone resistance is increasingly common and thought to be related to human and agricultural antibiotic use.
- Macrolide resistance is approximately 5%.
- Treatment duration for enteritis is 3–5 days.
- Appropriate bacteremia treatment should be based on antimicrobial susceptibility testing.

ADDITIONAL TREATMENT

General Measures

Immunocompetent children with diarrhea usually improve with

rehydration alone.

ISSUES FOR REFERRAL

Specific follow-up is unnecessary.

ADDITIONAL THERAPIES

Antimotility agents can prolong symptoms and should be avoided.

INPATIENT CONSIDERATIONS

Initial Stabilization

Correct initial dehydration.

Admission Criteria

Admit those requiring IV fluids.

IV Fluids

Use normal saline to correct dehydration. IV fluids should contain dextrose if being used for maintenance fluid requirements.

Nursing

Contact precautions are recommended for admitted infected infants and children incontinent of stool and should be maintained until they receive 48 hours of antibiotics.

Discharge Criteria

Discharge rehydrated patients able to maintain hydration orally.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

In untreated patients, the median organism excretion is 2–3 weeks but can be up to 3 months. Asymptomatic carriage is uncommon.

DIET

Avoid undercooked poultry and unpasteurized milk. Resume a normal diet when tolerated.

PATIENT EDUCATION

Symptoms resolve in 1 week for most people.

PROGNOSIS

For patients with enteritis, the prognosis is very good, regardless of whether antibiotic treatment is given.

COMPLICATIONS

- Postinfectious immunologic complications include reactive arthritis, GBS, Miller-Fisher syndrome (a GBS variant predominantly affecting eye movement), reactive arthritis, and erythema nodosum.
- GBS is estimated to affect 1 in 1,000 patients with *Campylobacter* infection.
- *C. jejuni* (serotypes O:19 and O:41) is the most frequently identified GBS cause and is responsible for up to 40% of U.S. GBS cases.
- HLA-B27 antigen is associated with reactive arthropathy. The estimated incidence of reactive arthritis after *Campylobacter* infection ranges from 0 to 7%.
- Children with high fever may develop seizures.
- Some studies have demonstrated associations between *Campylobacter* infection and both irritable bowel syndrome and inflammatory bowel disease.
- Spontaneous abortion and hemolytic uremic syndrome are described with *C. upsaliensis*.

CODES

ICD10

A04.5 *Campylobacter* enteritis

FAQ

- Q: Is treatment necessary for asymptomatic children when *Campylobacter* is isolated as the pathogen causing the enteritis?
- A: No treatment is needed in this situation.
- Q: Can one develop immunity to *Campylobacter* infections?
- A: Immunity to *C. jejuni* is acquired after 1 or more infections. For children living in endemic areas, effective natural immunity is a result of significant repeated early exposure.
- Q: How are *C. jejuni* infection and GBS related?
- A: Many strains of *C. jejuni* have surface glycolipids that are similar to gangliosides, which are abundant in the central and peripheral nervous systems. Anti-*Campylobacter* antibodies bind to the gangliosides through molecular mimicry, causing the demyelinating process characteristic of GBS.

CANCER THERAPY LATE EFFECTS

Kelly L. Neale • Tiffany Chang

BASICS

DESCRIPTION

The majority of children diagnosed with cancer will reach adulthood. Childhood cancer survivors require unique medical follow-up. Risks of late effects depend on the treatments received as well as the type and site of cancer. The Children's Oncology Group's long-term follow-up guidelines serve as the basis for many of the recommendations in this chapter.

EPIDEMIOLOGY

- Long-term survival into adulthood for a child diagnosed with cancer is nearly 80%.
- Among adults treated for childhood cancer:
 - Nearly 2/3 of survivors will develop one or more chronic health condition.
 - Nearly 1/3 of survivors will experience severe or life-threatening complications during adulthood.
- Approximately 270,000 childhood cancer survivors live in the United States.
- These numbers will continue to grow as new cancer therapies become available and more children survive.

RISK FACTORS

Late effects of cancer therapy are influenced by tumor-related treatment and host-related factors.

PATHOPHYSIOLOGY

Risk of organ dysfunction is related to primary cancer location and treatment used. See detailed systems-based evaluations in the following sections.

DIAGNOSIS

HISTORY

It is essential for the primary care physician to obtain a thorough cancer treatment summary, including the following:

- Date of diagnosis/age at diagnosis
- Type of cancer, stage, histology
- Site of primary tumor and metastatic sites
- Relapse(s) and date(s)
- Treatment modalities
 - Significant surgical procedures
 - Treatment protocol(s)
 - Chemotherapy
 - Drugs and cumulative dosages
 - Age of first anthracycline therapy
 - Radiation therapy (XRT)
 - Type
 - Site/dose
 - Total/boost doses
 - Hematopoietic stem cell transplant (HSCT)
 - Type and date of transplant
 - Source: bone marrow, cord blood, or peripheral blood stem cells
 - Conditioning regimen
 - Immunotherapy: types/cumulative doses

PHYSICAL EXAM

Annual physical exam of the entire body with particular attention to organ systems as listed in the following sections

SCREENING TESTS & INTERPRETATION (BY AT-RISK ORGAN SYSTEM)

Bladder Toxicity

- Chronic infections
 - Risk factors: cystectomy
- Hemorrhagic cystitis
 - Risk factors: ≥ 30 Gy XRT to spine, flank, abdomen, pelvis, bladder,

or total body irradiation (TBI)

- Bladder fibrosis and hemorrhagic cystitis
 - Risk factors: cyclophosphamide, ifosfamide
- Urinary incontinence or tract obstruction
 - Risk factors: pelvic surgery, hysterectomy
- Screen with annual urinalysis and detailed voiding history.

Bone Toxicity

- Decreased bone mineral density, osteopenia, osteonecrosis, increased risk of fractures
 - Risk factors: corticosteroids, methotrexate, ≥ 40 Gy XRT to any field, or HSCT
 - Evaluate bone density with DEXA scan.
- Scoliosis or kyphosis
 - Risk factors: spine or thoracic surgery, XRT to spine, chest, lungs, or abdomen
 - Spine exam annually until growth is complete
- Bone growth failure
 - Risk factors: XRT to any field, especially cranium, spine, trunk, or TBI
 - Measure height, weight, sitting height yearly.

Cardiovascular Toxicity

- Cardiomyopathy, left ventricular dysfunction, and arrhythmias
 - Risk factors: anthracyclines (daunorubicin, doxorubicin/Adriamycin, epirubicin, idarubicin, mitoxantrone) and/or XRT to the thorax or abdomen
 - Frequency of echocardiogram (ECHO)/multigated acquisition (MUGA) depends on cumulative dose of anthracyclines, age at first dose, and field of XRT (involving heart).
 - Consider close monitoring during pregnancy.
- Carotid artery or subclavian artery disease
 - Risk factors: ≥ 40 Gy XRT to head, neck, chest, lungs, or TBI
 - Examine for carotid bruits or diminished carotid/brachial/radial pulses.

ALERT

Anthracycline, antibiotics and XRT to the heart/chest/lungs/neck increases risk of cardiovascular disease; at-risk patients require detailed history, exam, and frequent ECHO/MUGA screening.

- Thrombosis at prior central venous catheter site
 - Inspect site for pain/swelling
- Dyslipidemia
 - Risk factors: TBI
 - Screen with fasting lipid panel every 2 years.
- Vasospastic attacks (Raynaud phenomenon)
 - Risk factors: vincristine or vinblastine

Dermatologic Toxicity

- Skin cancer, dysplastic nevi, fibrosis, alopecia, telangiectasias, nail/pigmentation changes
 - Risk factors: any XRT, HSCT with chronic graft-versus-host disease (cGVHD)
 - Encourage monthly self-skin exams.

Endocrine Toxicity

- Thyroid dysfunction, nodules, and cancer
 - Risk factors: XRT to neck, head, spine, mediastinum, TBI, or therapeutic systemic metaiodobenzylguanidine (MIBG)
 - Thyroid exam and TSH/free T₄ annually
- Growth hormone deficiency
 - Risk factors: XRT to cranium or TBI
 - Height, weight, BMI, Tanner stage every 6 months until mature, then annually
 - If at risk: insulin-like growth factor (IGF)-1, IGF-2, and IGFBP-3
- Central adrenal insufficiency
 - Risk factors: ≥ 30 Gy XRT to cranium, TBI
 - Screen: annual endocrinology visit
- Hyperprolactinemia
 - Risk factors: ≥ 40 Gy XRT to cranium, TBI
 - If symptomatic, screen with prolactin level
- Hypopituitarism
 - Risk factors: neurosurgery of brain, ≥ 30 Gy XRT to cranium, TBI

- Screening labs: cortisol, prolactin, testosterone/estradiol, IGF-1, TSH, FSH, LH
- Obesity
 - Risk factors: XRT to cranium, brain neurosurgery
 - Height, weight, BMI, BP annually

Gastrointestinal Toxicity

- Esophageal stricture
 - Risk factors: ≥ 30 Gy XRT to spine, neck, chest, lung, mediastinum, mantle, abdomen, TBI or HSCT with cGVHD
- Cholelithiasis
 - Risk factors: ≥ 30 Gy XRT to abdomen, flank, liver, kidneys, TBI
- Strictures, fistula, chronic enterocolitis
 - Risk factors: ≥ 30 Gy XRT to neck, chest, spine, abdomen, liver, kidneys, pelvis, TBI
- Bowel obstruction/adhesions
 - Risk factors: laparotomy or ≥ 30 Gy XRT to abdomen, pelvis, or spine
- Fecal incontinence
 - Risk factors: pelvic or spinal cord surgery, cystectomy

Hepatic Toxicity

- Chronic hepatitis C
 - Risk factor: blood products prior to 1993
 - Screen with Hep C antibody, PCR if positive
- Hepatic dysfunction
 - Risk factors: methotrexate, mercaptopurine (6-MP), thioguanine (6-TG), HSCT
- Veno-occlusive disease
 - Risk factors: mercaptopurine or thioguanine
- Baseline: ALT/AST/bili; ferritin after HSCT

Neurologic Toxicity

- Peripheral neuropathy
 - Risk factors: cisplatin, carboplatin, vincristine, or vinblastine
- Cerebrovascular complications
 - Risk factors: ≥ 18 Gy XRT to cranium or TBI

- Neurocognitive difficulties
 - Risk factors: brain neurosurgery, methotrexate, high-dose IV cytarabine, XRT to cranium, TBI
- Seizures, motor/sensory deficits, or hydrocephalus following brain neurosurgery
- Clinical leukoencephalopathy following methotrexate, high-dose IV cytarabine, or XRT to cranium or TBI
- Neuropathic pain risk following amputation
- Neurogenic bowel/bladder, incontinence, sexual dysfunction risk after spinal cord neurosurgery

Ophthalmologic Toxicity

- Cataracts/ocular issues
 - Risk factors: corticosteroids, busulfan, XRT to orbit/eye, cranium, or TBI
 - Annual funduscopy and visual acuity exams
 - Annual ophthalmologist exam as indicated

Ototoxicity

- Hearing loss, vertigo, or tinnitus
 - Risk factors: cisplatin, carboplatin: myeloablative or any does <1 year; XRT ≥ 30 Gy to ear, cranium, or TBI
 - Baseline audiogram (annually if loss detected)
 - Otoscopic exam annually

Oral Toxicity

- Tooth enamel dysplasia and root/tooth agenesis or root thinning/shortening
 - Risk factors: any chemotherapy (particularly at a young age), XRT to head/neck
- Xerostomia or salivary gland dysfunction
 - Risk factors: head/neck XRT or cGVHD
- Osteoradionecrosis
 - Risk factors: ≥ 40 Gy XRT to head, neck, TBI
- Oral exam annually; dental cleaning and exam every 6 months

Pulmonary Toxicity

- Fibrosis, dyspnea, decreased lung function

- Risk factors: bleomycin, busulfan, carmustine, lomustine, XRT to chest or lungs, or TBI
- If at risk, obtain baseline pulmonary function testing, and as clinically indicated

Psychosocial Disorders

- Neurocognitive, educational, or vocational difficulties
 - Risk factors: any treatment, especially methotrexate, high-dose cytarabine, brain neurosurgery or XRT to head or TBI
 - Educational/vocational assessment annually
 - Formal neuropsychological evaluation as indicated
- Posttraumatic stress, depression, anxiety, risky behaviors, body image disturbance
 - Risk factors: any cancer treatment
 - Assess mental health at each clinic visit.

Renal Toxicity

- Hypertension or renal dysfunction
 - Risk factors: nephrectomy or carboplatin, cisplatin, ifosfamide, methotrexate, or XRT to liver, kidneys, flank, abdomen, TBI, or HSCT
- Hydronephrosis, dysfunctional voiding, vesicoureteral reflux
 - Risk factors: cyclophosphamide, ifosfamide, ≥ 30 Gy XRT to abdomen, flank, or pelvis
- Urinary incontinence or tract obstruction
 - Risk factor: pelvic surgery
- Baseline: BUN/Cr, Na/K/Cl/CO₂, Mg, Phos, Ca
- Annual UA and BP if at risk or after nephrectomy

Reproductive Toxicity

- Gonadal dysfunction: infertility, azoospermia, oligospermia, hypogonadism, delayed or arrested puberty, sexual dysfunction, early menopause
 - Risk factors: spinal neurosurgery, orchiectomy, alkylating agents (busulfan, carmustine, chlorambucil, cyclophosphamide, ifosfamide, lomustine, mechlorethamine, melphalan, procarbazine, thiotepa), carboplatin, cisplatin, dacarbazine, temozolomide, XRT to gonads,

- pelvis, abdomen, cranium, or TBI
- Assess Tanner stage yearly until mature.
- Males: Screen with FSH/LH/testosterone at 14 years or if symptomatic and semen analysis as requested.
- Females: Screen with FSH/LH/estradiol at 13 years or with delayed puberty/amenorrhea/irregular menses/estrogen deficiency symptoms.

Subsequent Neoplasms

- Increased risk varies by host factors, primary cancer therapy, and environmental exposures.
- The Childhood Cancer Survivor Study reported a 30-year cumulative incidence of 20.5%.
- The risk of subsequent neoplasms (SNs) remains elevated for more than 30 years following primary cancer diagnosis.
- Patients with genetic cancer predisposition syndromes are at increased risk of SNs.
- 80% of SNs are solid tumors and demonstrate a strong relationship with ionizing radiation.
- Blood cancer: acute lymphoblastic leukemia (ALL), acute myeloid leukemia (AML) and therapy-related myelodysplastic syndrome (t-MDS)
 - Risk factors: alkylating agents, anthracyclines, carboplatin, cisplatin, dacarbazine, temozolomide
 - Topoisomerase II inhibitor–associated AML occurs 6 months to 3 years after exposure.
 - Alkylating agent–associated t-MDS/AML occurs 3–5 years after exposure.
 - Screen with annual complete blood count with differential for 10 years following treatment.
 - Perform dermatologic exam for petechiae, purpura, and pallor at each visit.
- Bladder cancer
 - Risk factors: cyclophosphamide, XRT to bladder, prostate, abdomen, pelvis, vagina, flank, inguinal region, or sacral/whole spine

- Obtain annual detailed voiding history.
- Bone cancer in any XRT field
 - Perform annual inspection/palpation of the bones/soft tissues/skin in XRT field.
- Brain tumors
 - Risk factors: XRT to cranium or TBI
 - Perform annual neurologic exam.
- Breast cancer
 - Risk factors: XRT to chest, lungs, mediastinum, axilla, mantle, or TBI
 - Annual breast exam from puberty to age 25 years; after age 25 years, perform every 6 months
 - ≥ 20 Gy XRT: annual mammogram and breast MRI beginning at age 25 or 8 years post XRT (whichever is last); 10–19 Gy XRT: consider testing
- Colorectal cancer
 - Risk factors: ≥ 30 Gy XRT to spine, liver, kidneys, flank, abdomen, pelvis, or TBI
 - Perform colonoscopy at age 35 years or 10 years after XRT (whichever is last), every 5 years.
 - Familial adenomatous polyposis (FAP), start colonoscopy at 21 years; hereditary nonpolyposis colorectal cancer (HNPCC), start at puberty
- Skin cancer
 - Risk factors: any XRT
 - Perform annual dermatologic exam in XRT field.
 - Encourage monthly self-skin exams.
- Thyroid cancer
 - Risk factors: XRT to cranium, neck, spine, supraclavicular, mediastinum, mantle, chest, lungs, or TBI
 - Perform annual thyroid exam.

TREATMENT

Treatment depends on long-term effects; see previous discussion for organ

system-specific follow-up care.

ONGOING CARE

- Regular visits with primary care provider and oncologist or long-term follow-up program
- Dental exams and cleanings every 6 months
- Promptly assess signs or symptoms of SNs.
- Assess psychosocial functioning at each visit.
- Maintain health insurance coverage.
- Immunizations may require updates.

ALERT

- Reimmunize after chemotherapy per oncologist and using Centers for Disease Control and Prevention (CDC) guidelines.
- Psychosocial assessment of the patient should be performed at each clinic visit.

FAQ

- Q: Who is considered a cancer “survivor”?
- A: Anyone from time of cancer diagnosis until end of life. Many long-term follow-up clinics specialize in patients who are 2 years post cancer therapy.
- Q: Where can I find the latest long-term follow-up guidelines for childhood cancer survivors?
- A: <http://www.survivorshipguidelines.org/>

CANDIDIASIS

Jessica E. Ericson • Daniel K. Benjamin, Jr.

BASICS

DESCRIPTION

Infection caused by species of the yeast, *Candida*; encompasses a spectrum of disease depending on host factors:

- Mucosal infection: oral thrush, esophagitis, vaginitis
- Cutaneous infection: diaper dermatitis, intertriginous dermatitis
- Disseminated candidiasis: candidemia, hepatosplenic candidiasis, meningitis, endocarditis, endophthalmitis

EPIDEMIOLOGY

Incidence

- Mucosal: Thrush occurs in ~5% of normal newborns.
- Disseminated: 3rd most common cause of bloodstream infection in hospitalized patients

RISK FACTORS

Immunocompromise (HIV, malignancy, neutropenia, transplant recipient, corticosteroid use), prematurity, burn injury, central venous catheter, parenteral nutrition, broad-spectrum antibiotic use

GENERAL PREVENTION

- Sterilize bottle nipples and toys to prevent reinfection with oral candidiasis.
- Avoid unnecessary broad-spectrum antibiotic use and limit duration when used.
- Remove indwelling IV catheters as soon as possible and maintain sterility with line care.
- Prophylaxis is indicated for some high-risk populations (preterm infants <750 g in high-incidence nurseries, neutropenic patients).

ETIOLOGY

- 20% of patients have GI or respiratory tract colonization. Neonatal

colonization is acquired from infected vaginal mucosa during birth. Incidence of colonization increases with age of the infant especially if exposed to antibiotics or poor hand washing. Colonization increases the risk of invasive infection.

- *Candida albicans* is the most common species isolated in children; non-*albicans* species are increasing in incidence: *Candida parapsilosis* > *Candida glabrata* > *Candida lusitanae* > *Candida krusei* > other.

COMMONLY ASSOCIATED CONDITIONS

Candida spp. may cause disease at any site.

- Mucosal candidiasis
 - Oropharyngeal candidiasis (thrush) occurs in 5% of normal infants. In older children, it is associated with use of antibiotics, inhaled corticosteroids or immunosuppressive drugs, conditions of endocrine or immune dysfunction, and malignancy.
 - Perlèche (angular cheilosis) is characterized by fissuring, erythema, and pain at the corners of the mouth; more common in children who lick their lips frequently or have vitamin deficiencies
 - Esophageal candidiasis occurs in HIV-infected patients and those on immunosuppressive therapy; 30% have associated thrush.
- Cutaneous candidiasis
 - Diaper dermatitis is most common during infancy because of predisposing factors found with diaper use—warm, moist environment. May co-occur with thrush.
 - Intertriginous candidiasis occurs in skinfolds where there are opposing skin surfaces; generally occurs in healthy patients with the risk factors of chronic moisture, recent antibiotic use, or obesity
- Vaginal candidiasis: Oral contraceptives, antibiotics, pregnancy, corticosteroids, and immunodeficiency are predisposing conditions; classified as uncomplicated or complicated
 - Uncomplicated (90%): mild to moderate; sporadic; organism is *C. albicans*; normal host
 - Complicated (10%): presence of any one of the following factors defines a complicated infection: severe, recurrent (>4 episodes/year) infection by non-*albicans* *Candida* spp. or predisposing host factor (immunocompromised, diabetes mellitus [DM], etc.)

- Congenital candidiasis: cutaneous infection acquired from infected amniotic fluid. Usually has an excellent prognosis.
- Invasive candidiasis
 - Defined as candidemia and disseminated candidiasis (including hepatosplenic candidiasis). Candida from a blood culture should never be considered a contaminant.
 - Risk factors include prematurity, malignancy, immunodeficiency syndromes, DM, broad-spectrum antibiotic therapy, corticosteroids, chemotherapy, hyperalimentation, indwelling catheters, ICU stay, recent complex surgery, and stem cell or organ transplantation.
 - The most frequent sites of involvement are the GI tract, lungs, kidneys (pyelonephritis, mycetoma), liver, spleen, eyes, and brain (meningoencephalitis). Fungal sepsis may occur. Peritoneal, urinary tract, and cardiac valve candidal infections are most often related to instrumentation or catheterization in the immunocompromised host.
- Chronic mucocutaneous candidiasis
 - Noninvasive infection of the skin, hair, mucous membranes, and nails
 - Typically seen in the 1st year of life, and almost all cases occur within the 1st decade
 - Caused by a T-cell defect resulting in decreased production of Candida-specific antibody. Patients lack a delayed-type hypersensitivity reaction to intradermal injection of candidal antigens. May be part of polyglandular autoimmune syndrome type 1.

DIAGNOSIS

HISTORY

- Recurrent infection
 - In oral thrush, reinfection may occur from nipples, pacifiers, or toys.
 - In recurrent vaginitis, bacterial or non-albicans Candida spp. infections are possible.
- Recent antibiotic use: Thrush often occurs in infants but may occur in normal older children after treatment with systemic antibiotics.

- Predisposing conditions: Systemic dissemination of infection is more likely with impaired immunity.
- Visual changes or discomfort: Features of endophthalmitis include eye pain, blurred vision, scotomata, and photophobia.
- Pain with eating or swallowing: thrush or esophagitis. Esophagitis will often give localized retrosternal pain.

PHYSICAL EXAM

- Oral lesions
 - White cottage cheese–like adherent plaques on tongue, buccal mucosa, pharynx, and gingiva
 - Difficult to scrape away; underlying mucosa may be ulcerated.
- Retinal exam
 - All patients with candidemia should have a dilated retinal exam by an ophthalmologist to assess for endophthalmitis.
 - Chorioretinitis with vitreal haze may be seen.
- Rash
 - Scattered erythema with pustules and papules that become confluent over time. Superficial scale and satellite lesions are classically seen.
 - In neonates with congenital candidiasis, rash is present at birth or develops in 1st week of life. A diffuse macular rash is often accompanied by vesicles and pustules; nails may also be involved.
 - Patients with invasive candidiasis may also present with a diffuse, erythematous rash.
- Vaginitis: white or watery vaginal discharge, erythematous vaginal mucosa with adherent white plaques

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Direct light microscopic examination of specimen
 - Simple, cost-effective way to confirm clinical diagnosis of mucosal, cutaneous, and vaginal candidiasis; performed using material scraped gently from lesions
 - Potassium hydroxide [KOH] preparation (10% KOH) allows visualization of the long, branching hyphae of *C. albicans*.
- Fungal culture

- *Candida* spp. can be isolated from culture of mucosal or cutaneous scrapings, blood, urine, CSF, bone marrow, tissue biopsy, abscess aspirate, and bronchoalveolar lavage fluid.
- However, the sensitivity of blood culture is only 50–60% in patients with invasive candidiasis and may be lower in neonates.
- Adjunctive tests
 - β -D glucan assay looks for this component of the fungal cell wall in the bloodstream.
 - Not well studied in children yet but may allow for earlier diagnosis of disseminated disease

Imaging

CT scan, ultrasound, and echocardiogram: Important to identify deep organ lesions (liver, spleen, brain, kidney, or heart) associated with disseminated infection as surgery or more aggressive treatment may be necessary.

DIFFERENTIAL DIAGNOSIS

- Oral lesions: aphthous stomatitis, acute necrotizing gingivitis, herpes gingivostomatitis, coxsackievirus
- Cutaneous: atopy, seborrhea, bacterial skin disease, scabies, irritant dermatitis
- Vaginitis: irritant, bacterial
- Congenital candidiasis: viral infections (especially herpes viruses), bacterial infections, benign neonatal skin conditions
- Invasive candidiasis: bacterial infection

TREATMENT

MEDICATION

- Oral candidiasis: nystatin suspension until 2 days after lesions have cleared. In older patients, nystatin as a swish-swallow suspension or in oral tablet form for >7 days is effective. Clotrimazole lozenges can be used in older patients: 10 mg dissolved in mouth 5 times daily for 7 days.
 - Fluconazole and ketoconazole are effective for infections that are

persistent or occur in immunocompromised hosts. Often, a single dose is effective.

- Esophageal candidiasis
 - A therapeutic trial with fluconazole for patients with presumed esophageal candidiasis is a cost-effective alternative to endoscopy.
 - Symptoms should resolve within 7 days after the start of therapy.
 - A 14–21-day course is recommended. Itraconazole solution and IV amphotericin B are acceptable alternatives.
- Cutaneous
 - Keep the area dry. Topical nystatin, clotrimazole 1%, or miconazole 2% 3–4×/day until the rash has cleared. Brief addition of a topical steroid may improve inflammatory changes.
- Uncomplicated vaginal candidiasis
 - Topical agents are highly effective in uncomplicated infections (cure rates >80%): clotrimazole, miconazole, butoconazole, and terconazole (dose varies with 1-, 3-, or 7-day treatment).
 - Oral agents are also effective: fluconazole (10 mg/kg up to 150 mg as a single dose)
- Complicated vaginal candidiasis
 - Extend anti-yeast therapy to 7–14 days.
 - Non-albicans species of *Candida* usually respond to topical boric acid (600 mg/24 h for 14 days). Azole-resistant *C. albicans* infections are extremely rare in the immunocompetent host.
- Recurrent vaginitis (more than 4 episodes of proven infection during a 12-month period, still usually due to azole-susceptible *Candida* sp.)
 - Induction therapy with 2 weeks of a topical or oral azole is followed by a maintenance regimen for 6 months.
 - Suitable maintenance regimens include fluconazole (150 mg once weekly), ketoconazole (100 mg daily), itraconazole (100 mg every other day), or daily therapy with a topical azole.
- Systemic or disseminated candidiasis
 - Begin treatment in hospital because of severity of illness, underlying disease process, and need for the IV route of drug administration.
 - Address predisposing factors (remove indwelling catheters, reduce

immunosuppression if possible).

- Antifungal agents commonly used in children include amphotericin B, fluconazole, and, increasingly, echinocandins (micafungin, caspofungin).
- Fluconazole (12 mg/kg/24 h with 25 mg/kg/day loading dose) may be used empirically in those who are less critically ill. Many *C. glabrata* and *C. krusei* are resistant.
- An echinocandin or lipid formulations of amphotericin B should be used for severe illness and in neutropenic hosts. They are also approved for candidal esophagitis.
- Amphotericin B (1 mg/kg/24 h IV) is rarely used due to availability of less toxic agents.
- Lipid-based amphotericin B (3–6 mg/kg/24 h IV)
- Duration of therapy varies based on sites affected: candidemia (3 weeks), candidal meningitis (4 weeks), endophthalmitis (6–12 weeks), endocarditis (>6 weeks following surgical therapy), and osteomyelitis (6–12 months).

ALERT

- Recurrent thrush in a breastfed infant may indicate *C. albicans* colonization of the mother's nipples; this can be eliminated by treatment of the nipples with nystatin cream.
- Candidal diaper dermatitis should prompt an oral exam as thrush is often coexistent.
- Maintain a high index of suspicion for invasive candidiasis in an immunocompromised patient. Persistent fevers despite antibiotic therapy, diffuse rash, and visual complaints are important clues.
- Blood culture growth of *Candida* should never be regarded as a contaminant but should prompt investigation for invasive disease.

FAQ

- Q: When should an older child with thrush be evaluated for possible immunodeficiency?
- A: Thrush in the older child is usually caused by recent antibiotic or steroid treatment or diabetes. If no explanatory cause is identified, further evaluation that includes HIV testing should be considered.

CARBON MONOXIDE POISONING

Kevin C. Osterhoudt

BASICS

DESCRIPTION

- Carbon monoxide (CO) is an odorless gas produced via incomplete combustion of carbonaceous fuels.
- CO poisoning occurs when carboxyhemoglobin and CO accumulation leads to impaired physiologic function.

EPIDEMIOLOGY

CO poisoning is a leading cause of death by poisoning within the United States.

Incidence

- More than 13,000 CO exposures were reported to the American Association of Poison Control Centers in 2011, with ~1/3 of such exposures occurring in children.
- Seasonal cold weather and other natural disaster events lead to increases in incidence of exposure.

GENERAL PREVENTION

- Furnaces should receive regular maintenance by skilled technicians.
- Automobiles, gas-powered machinery, and nonelectrical space heaters should only be used with proper ventilation.
- CO detectors should be installed within living spaces.

PATHOPHYSIOLOGY

- On inhalation, some CO binds to hemoglobin to form carboxyhemoglobin.
- Carboxyhemoglobin does not carry oxygen.
- Carboxyhemoglobin produces an allosteric leftward shift of the oxyhemoglobin dissociation curve.
- Carboxyhemoglobin elimination half-life
 - ~4 hours in room air

- 1–2 hours in 100% oxygen
- 20 minutes in 100% oxygen at 3 atmospheres
- CO interacts with cellular proteins, leading to impaired mitochondrial function.
- CO is a source of oxidative stress and poisoning may begin a cascade of inflammatory vasculitis within the CNS and heart.

ETIOLOGY

- Common sources of CO exposure include the following:
 - Automobile or boat exhaust
 - Smoke inhalation from house fires
 - Oil, gas, or kerosene space heaters or cooking stoves
 - Portable electricity generators and construction equipment
 - Faulty home furnaces
- The solvent methylene chloride is metabolized to CO by the liver after ingestion, inhalation, or dermal absorption.
- CO is a component of cigarette smoke and environmental air pollution.
- CO is a naturally occurring by-product of the heme biosynthesis pathway.

COMMONLY ASSOCIATED CONDITIONS

Victims of house fires may suffer from thermal injury and/or cyanide poisoning.

DIAGNOSIS

Many emergency medical services crews carry CO detectors.

HISTORY

- Health of family members?
 - CO is an environmental gas that often sickens multiple household members.
- Use of furnace or space heaters?
 - May suggest source of exposure
- Time of exposure?
 - Carboxyhemoglobin levels must be interpreted with consideration

to their timing.

- Duration of exposure?
 - Toxicity is related to both magnitude and duration of exposure.
- Loss of consciousness?
 - Syncope appears to be the best clinical predictor of delayed neurologic sequelae.
- Signs and symptoms
 - Mild CO intoxication
 - Malaise
 - Nausea
 - Light-headedness
 - Headache
 - Vomiting
 - Moderate to severe CO intoxication
 - Confusion
 - Syncope
 - Weakness
 - Angina

PHYSICAL EXAM

- Soot on nasal mucosa: suggests possibility of thermal pulmonary injury
- Hypotension: suggests severe CO poisoning
- Cherry red skin: This classic sign is mostly a postmortem finding.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- CO-oximetry: allows quantitation of carboxyhemoglobin
- Arterial blood gas: allows accurate assessment of oxygenation
- Hemoglobin quantitation: The percentage of carboxyhemoglobin concentration must be considered in relation to the total hemoglobin.
- Serum bicarbonate: A wide anion gap metabolic acidosis suggests the accumulation of lactate, which may result from severe CO poisoning or concomitant cyanide poisoning.
- Creatine kinase: CO poisoning victims are susceptible to rhabdomyolysis.
- Troponin: CO poisoning may lead to myocardial injury.

- ECG: Hypoxemia and metabolic poisoning may lead to cardiac ischemia.
- Transcutaneous carboxyhemoglobin measurement devices are now marketed.

Imaging

- Neuroimaging
 - Not routinely helpful in acute management
- Globus pallidus and subcortical white matter changes may be seen after severe or chronic CO poisoning.

ALERT

Pitfalls

- Pulse oximetry frequently overestimates the percentage of oxyhemoglobin.
- Smokers may have carboxyhemoglobin levels up to 10%.
- Hemolysis, or the presence of fetal hemoglobin, may lead to mild elevation of carboxyhemoglobin.
- In-hospital carboxyhemoglobin levels are not good at predicting risk of delayed neurologic sequelae.

DIFFERENTIAL DIAGNOSIS

- Influenza
- Gastroenteritis
- Vasomotor syncope
- Asphyxia
- Stroke

TREATMENT

GENERAL MEASURES

- Recognize CO exposure.
- Remove patient from source of CO.

Initial Stabilization

Administer 100% oxygen at least until patient is asymptomatic and carboxyhemoglobin level is <5–10%.

ADDITIONAL TREATMENT

- Consider hyperbaric oxygen treatment referral to prevent delayed neurologic sequelae.
- Relative indications
 - Loss of consciousness
 - Seizures
 - Pregnancy
 - Persistent neurologic symptoms
 - CO concentration >25%
- Contraindications
 - Concurrent illness or injury requiring ongoing acute care
 - Unvented pneumothorax
 - Lack of accessible hyperbaric oxygen chamber
- Complications
 - Barotitis media
 - Tympanic membrane rupture
 - Claustrophobic anxiety
 - Seizure
 - Pneumothorax

ALERT

Pitfalls

- Failure to differentiate CO poisoning from winter viral illness
- Syncope may be hard to discern in young infants.
- Undue delay in hyperbaric oxygen therapy, which is most effective in first 6 hours after exposure

ISSUES FOR REFERRAL

- Neuropsychological testing may benefit individuals with perceived neurocognitive deficits.
- Cardiac evaluation for those with myocardial ischemia

INPATIENT CONSIDERATIONS

Admission Criteria

- Perceived merit of hyperbaric oxygen therapy
- Persistent neurologic symptoms
- Evidence of myocardial ischemia

- Associated injuries that merit hospitalization

Discharge Criteria

- Conclusion of hyperbaric therapy
- Stable cardiovascular and neurologic systems after elimination of excess carboxyhemoglobin

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Delayed neurologic sequelae may develop 2–40 days after exposure.

PROGNOSIS

- Acute mortality appears to be caused by carboxymyoglobin formation and ischemic ventricular dysrhythmia.
- Patients stable on presentation to medical care have a good prognosis for recovery.
- Delayed neurologic sequelae may manifest in as many as 10–40% of patients after a CO-mediated syncopal episode.

COMPLICATIONS

- Death
- Delayed neurologic sequelae, for example
 - Neurocognitive deficits
 - Personality changes
 - Parkinsonism

- T58.01XA Toxic effect of carb monx from mtr veh exhaust, acc, init

FAQ

- Q: At what carboxyhemoglobin level should hyperbaric oxygen therapy be recommended?
- A: In practice, most dissociation of carboxyhemoglobin occurs with administration of normal-pressure oxygen before hyperbaric therapy can be administered.
- The advocated value of hyperbaric oxygen is to limit cerebral ischemic reperfusion injury in an effort to ameliorate delayed neurologic sequelae.
- Carboxyhemoglobin levels may not directly correlate in this risk stratification, and the occurrence of syncope or seizure may be used as a surrogate marker.
- Currently, patients with CO concentrations >25% may be considered as potential candidates for hyperbaric oxygen.
- Q: In a household, which family member is at greatest risk of CO poisoning?
- A: Smaller and younger children have greater minute ventilation rates and may attain higher carboxyhemoglobin concentrations at a given exposure level.
- It is possible that developing brain tissue is more susceptible to the deleterious effects of CO poisoning.

CARDIOMYOPATHY

Kimberly Molina • Nelangi Pinto

BASICS

DESCRIPTION

Cardiomyopathy (CM) is defined as a disease of the heart muscle, which results in impaired function (systolic, diastolic, or both). It is classified based on structural and functional abnormalities:

- Dilated cardiomyopathy (DCM): The key finding is impairment of ventricular systolic function with cardiac dilation. Predominantly involves the left ventricle (LV) and manifests as congestive heart failure (CHF).
- Hypertrophic cardiomyopathy (HCM): Excessive thickening of the LV that is not secondary to load conditions, such as aortic stenosis or hypertension. Up to 20–25% of patients exhibit LV outflow tract obstruction.
- Restrictive cardiomyopathy (RCM): A myocardial disease in which there is impairment of ventricular diastolic function (or relaxation) from increased stiffness of the ventricle. This results in decreased ventricular filling while systolic function is generally preserved.
- Left ventricular noncompaction (LVNC): A disease where the myocardium of the LV has not completely compacted, resulting in persistence of trabeculations and myocardial dysfunction.

EPIDEMIOLOGY

Incidence

- Overall incidence of CM is 1–2 cases per 100,000 children per year. There is a peak incidence during the 1st year of life and a 2nd peak in adolescence.
 - DCM: 0.3–2.6 cases per 100,000 children per year
 - HCM: 0.3–0.5 cases per 100,000 children per year

Prevalence

- DCM: 36 cases per 100,000 people

- HCM: ~10–20 cases per 100,000 people
- RCM: Least common form of CM (<5%)
- LVNC: ~9% of CM cases

RISK FACTORS

Genetics

- DCM: familial DCM ~20% of cases
 - Autosomal dominant inheritance remains the most common pattern. Although no specific gene has been identified as the cause of familial DCM, 6 genes have been localized in different family cohorts.
 - DCM has also been seen in association with diseases of X-linked inheritance, such as Duchenne and Becker muscular dystrophy and Barth syndrome.
 - May also be inherited via mitochondrial DNA, with differing penetrance
- HCM: ~60% of reported cases are thought to be inherited. Traditionally, HCM is inherited in an autosomal dominant pattern with incomplete penetrance.
- RCM: Idiopathic cases may have a familial occurrence and may be associated with a skeletal myopathy. An autosomal dominant form of the disease with variable penetrance has been associated with Noonan syndrome.
- LVNC: familial in 20–30%. May be X-linked, mitochondrial, autosomal recessive, or dominant

ETIOLOGY

- DCM: There are many etiologies for DCM. Etiology is identified only ~30% of the time.
 - Of known causes, the most common is myocarditis (coxsackievirus B, echovirus, adenovirus). DCM can also occur from toxin exposure (anthracyclines), ischemic coronary artery disease (anomalous left coronary artery from the pulmonary artery, coronary aneurysms), and chronic tachyarrhythmias.
 - Can occur as a finding associated with another disease or syndrome. These include X-linked muscular dystrophies, inborn errors of fatty

acid oxidation, disorders of mitochondrial oxidative phosphorylation, nutritional deficiencies, and primary and secondary carnitine deficiency.

- It may be familial and genetically inherited.
- DCM is most commonly idiopathic.
- HCM: Etiology is known about 25% of the time. Often genetically inherited. Caused by myocyte hypertrophy with fibrillin disarray.
- RCM: Most commonly idiopathic, although known causes include the following:
 - Systemic disease such as lupus erythematosus, sarcoidosis, amyloidosis, infiltrative diseases (Gaucher disease, Hurler syndrome), storage diseases (Fabry disease), carcinoid syndrome, and radiation-induced fibrosis
 - Familial forms of RCM

DIAGNOSIS

In the early stages of all 3 forms of CM, the symptoms are nonspecific and can mimic other disease processes. The cardiac examination can be completely normal. Therefore, those patients who raise suspicion for this disease either by family history or clinical presentation should be carefully evaluated.

HISTORY

- DCM: Symptoms usually develop slowly, although they may also be of sudden onset:
 - Irritability
 - Respiratory distress
 - Dyspnea with exertion
 - Anorexia, abdominal pain, nausea
 - Failure to thrive
 - Exercise intolerance
 - Syncope
 - Palpitations
- HCM: Children are often asymptomatic and are first referred for

evaluation based on family history or for murmur evaluation. Of those with symptoms, the following may be present:

- Chest pain with exertion
- Dizziness
- Syncope
- Palpitations
- RCM: Symptoms are usually due to systemic and pulmonary congestion from high atrial pressures. They are usually more evident late in the disease:
 - Dyspnea with exertion
 - Abdominal pain
 - Chest pain
 - Palpitations

PHYSICAL EXAM

- Cardiac
 - DCM: tachycardia, cardiomegaly, hepatomegaly, S₃ or S₄ gallop; evidence of CHF and decreased cardiac output
 - HCM: can be normal or have systolic murmur owing to mitral regurgitation and/or LV outflow tract obstruction. The presence of outflow tract obstruction produces a systolic ejection murmur of variable intensity related to the degree of obstruction; the murmur increases in intensity with Valsalva and decreases in magnitude with squatting. A parasternal or carotid thrill or S₄ gallop may be present.
 - RCM: Jugular venous pulse either fails to fall or rises during inspiration (Kussmaul sign): the presence of S₃ or S₄. Advanced cases may exhibit weak peripheral pulses as evidence of low cardiac output.
- Respiratory (DCM and RCM): tachypnea, rales, wheezing
- Abdominal (DCM and RCM): hepatomegaly, ascites, tenderness to palpation

DIAGNOSTIC TESTS & INTERPRETATION

Lab

Initial lab tests

DCM: In addition to routine inflammatory markers, specific tests should

be obtained to establish etiology:

- Metabolic: carnitine level, serum organic acids, and urine organic and amino acids, pyruvate, lactate, thyroid function tests
- Genetic: chromosomal analysis, mutations of the dystrophin gene
- Infectious: enterovirus, coxsackievirus A/B, hepatitis, cytomegalovirus, Epstein-Barr virus, adenovirus, parvovirus, herpes simplex virus, and human immunodeficiency virus
- Brain natriuretic peptide (BNP) is often used to follow heart failure in patients with CM.

Imaging

Echocardiogram

- Allows for assessment of systolic function, ventricular dimensions, outflow tract obstruction, and diastolic filling properties
- DCM: significant dilation of left (and right) ventricle with decreased systolic function
- HCM: gold standard for diagnosis: LV hypertrophy, intraventricular pressure gradient, and systolic anterior motion of the mitral valve
- RCM: disproportionately dilated atria with impaired diastolic filling by Doppler. LV function is normal until late stages.
- LVNC: deep trabeculations and intertrabecular recesses in the LV, ventricular hypertrophy, and systolic dysfunction

Diagnostic Procedures/Other

- Nonspecific tests
 - Chest radiograph: cardiomegaly, pulmonary venous congestion, pulmonary edema, and pleural effusions; segmental atelectasis from bronchiole compression
 - Electrocardiogram: Supraventricular or ventricular arrhythmia may be seen.
 - DCM: sinus tachycardia, nonspecific ST segment, and T-wave changes
 - HCM: hypertrophy, deep Q waves
 - RCM: atrial enlargement, nonspecific ST and T-wave changes
 - LVNC: marked ventricular hypertrophy, T-wave inversion
- Cardiac catheterization
 - DCM: rarely used as the primary diagnostic tool; the procedure is

used to delineate coronary anatomy and to perform endomyocardial biopsies.

- HCM: determination of the presence or absence of LV outflow tract obstruction, evaluation of diastolic dysfunction, classic spike and dome arterial pulse tracing, Brockenbrough phenomenon (a beat following a premature ventricular contraction exhibits an arterial pulse pressure less than that of a control beat)
- RCM: Atrial pressures are elevated from increased LV and right ventricle (RV) end-diastolic pressures. Ventricular pressures exhibit a rapid and deep early decline at the onset of diastole followed by a rapid rise to a plateau in early diastole (dip and plateau or square root sign).

DIFFERENTIAL DIAGNOSIS

- DCM: Presentation may mimic other diseases:
 - Abdominal distention, right upper quadrant pain, nausea, and anorexia indicate right heart failure but could be mistaken for hepatic or gallbladder disease.
 - Wheezing, tachypnea, and dyspnea on exertion may be diagnosed as asthma.
 - Cardiomegaly on chest radiograph may be mistaken for a large pericardial effusion.
- HCM: This disease must be differentiated from LV hypertrophy seen in a well-trained athlete.
- RCM: should be distinguished from constrictive pericarditis because the latter is usually a remediable process. A history of tuberculosis, trauma, or cardiac surgery may suggest constrictive pericarditis.

TREATMENT

GENERAL MEASURES

- DCM
 - At diagnosis, a trial of IV γ -globulin and/or other immunomodulators (prednisone, azathioprine) to treat possible myocarditis, although impact on outcomes is unclear

- Diuretics
- Afterload reduction (enalapril, captopril)
- Inotropic agents (milrinone, dobutamine, digoxin)
- Aldactone (improves New York Heart Association [NYHA] functional class)
- Anticoagulation to avoid embolic complications
- Antiarrhythmics as needed
- β -adrenergic blockers (metoprolol, carvedilol)
- Ventricular assist devices have been used in those with end-stage heart failure either as a bridge to recovery or to transplantation.
- HCM: β -adrenergic blockers remain 1st-line medical therapy. Calcium channel blockers or disopyramide may also be used. Antiarrhythmics may also be part of the medical regimen. There is no evidence that prophylactic medical treatment will reduce the risk of sudden death.
 - If medical therapy is not effective, other options may include septal myectomy (for severe outflow obstruction) and atrioventricular sequential pacing.
 - The placement of an implantable cardioverter-defibrillator (ICD) may be indicated.
- RCM: The mainstay of medical therapy is symptomatic treatment.
 - Diuretics can be used with caution to treat venous congestion without reducing the ventricular filling pressure.
 - Antiarrhythmics are used to treat the high incidence of atrial arrhythmias.
 - ICDs have also been used to treat life-threatening ventricular arrhythmias.
 - Anticoagulation is used owing to the high risk of thrombus formation and embolic complications from hemostasis in the dilated atrium.
 - Due to natural history of disease, most patients eventually require a cardiac transplant.
- Patients with cardiomyopathies are generally restricted from strenuous exercise due to increased risk of sudden cardiac death.

SURGERY/OTHER PROCEDURES

- DCM or RCM: heart or heart–lung (if the pulmonary vascular

resistance is elevated) transplantation; transplantation may be necessary if all therapeutic endeavors prove to be futile.

- HCM: septal myectomy if indicated

INPATIENT CONSIDERATIONS

Initial Stabilization

Patients with DCM may present critically ill, requiring intubation and inotropic support.

ONGOING CARE

PROGNOSIS

- DCM: The rate of death or transplant is ~30% at 1-year and 40% at 5-year follow-up. Age (<1 month and >6 years), ventricular function, and symptoms of CHF at diagnosis are risk factors for a worse outcome. Biopsy-proven myocarditis is associated with improved outcome.
- HCM: Overall incidence of sudden death is 4–6% in children and adolescents and as low as 1% in adults. Between the ages of 12 and 35 years and in young athletes, HCM is the most common cause of sudden death. Obstruction may slowly develop or progress. Heart failure symptoms usually do not occur until adulthood. Survival is poorer (82%) for those diagnosed at <1 year of age.
- RCM: The reported median survival in RCM is 1.4 years in children with <20% freedom from death or transplant at 5 years.
- LVNC: 5-year survival free of death or transplantation is 75%.

COMPLICATIONS

- CHF can occur in all forms of CM.
- Arrhythmias may be seen and are frequently ventricular in origin.
- Thrombus formation can be seen owing to the stasis of blood in dilated cardiac chambers and the hypocontractile ventricle. Therefore, systemic or pulmonary emboli are possible.

CODES

ICD10

- I42.9 Cardiomyopathy, unspecified
- I42.0 Dilated cardiomyopathy
- I42.5 Other restrictive cardiomyopathy

FAQ

- Q: Should family members be evaluated once CM is diagnosed in a 1st-degree relative?
- A: Yes. In some forms of CM, there is a strong genetic component and family members should be evaluated. If the CM is known to be acquired, evaluation of relatives is not required.
- Q: Does the CM of infants of diabetic mothers carry the same clinical course and outcome as that of patients with HCM?

- A: No. The pathophysiology is initially similar in that asymmetric hypertrophy of the ventricular septum is often seen with or without LV outflow obstruction. However, the clinical course of CM in these infants is usually benign and resolves within the first 6 months of life.
- Q: What are the differentiating features of HCM and the benign physiologic hypertrophy of an athlete's heart?
- A: Several criteria are used to make this distinction. For example, a familial history of HCM raises the suspicion of this entity. Studies have suggested specific echocardiographic LV dimensions to differentiate benign hypertrophy and HCM (i.e., a wall thickness of ≥ 15 mm or LV cavity dimension < 45 mm are more consistent with HCM). Also, evidence of abnormal mitral valve inflow is suggestive of HCM.

CATARACT

M. Edward Wilson • Courtney L. Kraus

BASICS

DESCRIPTION

Cataract is the term used for any opacification of the crystalline lens of the eye.

EPIDEMIOLOGY

- Approximately 4 children per million total population will be born with bilateral congenital cataracts in developed countries.
- Adjusted cumulative incidence is 2.49 per 10,000 in the 1st year of life, increasing to 3.46 by age 15 years.

GENERAL PREVENTION

- There is currently no known way to prevent congenital cataracts. Timely prenatal diagnosis and treatment of intrauterine infections can prevent associated infant morbidities, including secondary cataracts. Correcting an underlying metabolic abnormality and minimizing exposure to inciting agents also reduces risk.
- It is essential that all newborns (and all children) receive screening eye examinations by health care providers. In much of the world, early diagnosis and referral is still the limiting factor for a child's ultimate visual prognosis.

PATHOPHYSIOLOGY

- Derangement of the normal developmental growth of the crystalline fibers of the central lens nucleus or peripheral lens cortex. The location of the opacity often suggests the congenital or early acquired onset.
- Frequently classified according to morphology or etiology
- Dense central opacities of ≥ 3 mm are visually significant and may produce visual disability.

ETIOLOGY

- Congenital or developmental: About 2/3 are idiopathic, the remainder

being inherited or associated with systemic disorders.

- Hereditary: Autosomal dominant transmission is responsible for 75% of bilateral hereditary cataracts. Most affected individuals are otherwise healthy.
 - Phenotypically identical cataracts can occur with mutations at different genetic loci and phenotypically variable cataracts can be found within a single family.
 - Multiple contributing genetic loci have been identified.
 - Rare hereditary syndromes combine cataracts with systemic disease. These are listed in the following discussion.
- Acquired
 - Toxic: may result from chronic steroid use or radiation exposure
 - Traumatic: may result from either blunt or penetrating ocular trauma
 - Inflammatory: from chronic uveitis
- Ocular abnormalities: Cataracts may be associated with primary ocular abnormalities such as aniridia, coloboma, and microcornea.

COMMONLY ASSOCIATED CONDITIONS

- Prenatal factors: intrauterine infection, fetal alcohol syndrome
- Metabolic and endocrine: galactosemia, neonatal hypoglycemia, hypoparathyroidism, diabetes mellitus, homocystinuria, Fabry disease, Wilson disease, mannosidosis
- Chromosomal: trisomy 21 (Down syndrome), 18, 13, or 15; Turner syndrome
- Dermatologic: congenital ichthyosis, hereditary ectodermal dysplasia, infantile poikiloderma, Gorlin syndrome
- Renal: Lowe and Alport syndromes
- Musculoskeletal: Marfan, Conradi, and Albright syndromes; myotonic dystrophy
- Rheumatologic: juvenile idiopathic arthritis, other uveitis (psoriatic, HLA-B27, etc.)
- Other: craniofacial and mandibulofacial syndromes, neurofibromatosis

DIAGNOSIS

HISTORY

- Decreased visual fixation and tracking? Cataracts may decrease vision.
- Sun sensitivity or squinting in bright light? Cataracts may cause glare and light scatter.
- Strabismus (ocular misalignment)? May indicate loss of vision in one eye
- White pupil? Cataracts may appear as a white spot in or under the pupil.
- Asymmetric or abnormal pupillary reflections (red eyes) with flash photography? Cataract may block the normal red reflex.
- Nystagmus (rhythmic oscillations)? May be a sign of severe, usually bilateral, vision loss
- Ocular trauma? Cataract can occur from blunt or penetrating trauma.
- Delayed development? Especially with significant bilateral congenital cataracts
- Careful family and prenatal history? Congenital cataracts can be inherited as an isolated condition. Intrauterine infection or alcohol exposure can cause cataracts.
- Positive family history or known history of an associated systemic condition?

PHYSICAL EXAM

- Decreased visual acuity: In preverbal child, assess and compare ability to fixate and follow with each eye. In verbal child, assess with pictures, HOTV matching, or alphabet (Snellen) eye chart.
- Leukocoria: white pupil
- Red reflex: absent, asymmetric, or irregular. How much of the pupil is obscured? Use direct ophthalmoscope held at an arm's length to illuminate both eyes and compare the red reflex from each eye.
- Strabismus: often an indication; cataract is long-standing and amblyopia likely.
- Nystagmus: will first appear at 2–3 months of age if vision deprivation from cataract is present at birth. Very poor prognostic sign for full vision recovery unless treatment is prompt.
- Laterality of disease: Bilateral cataracts may be due to systemic disease.

- Globe (eyeball) size: Microphthalmia (small eye) suggests congenital cataracts.
- Complete physical exam: to assess for associated conditions

DIAGNOSTIC TESTS & INTERPRETATION

Labs

For cases with a definitive etiology, laboratory evaluation is typically not necessary. For bilateral cataracts without a clear cause, a selective workup to rule out associated conditions may be indicated.

- Serologies: titers to rule out TORCH infections; blood glucose, calcium, and phosphate to exclude metabolic disorders such as diabetes and hypoparathyroidism
- Urine tests: reducing substances to rule out galactosemia; protein, amino acids, and pH to rule out Lowe syndrome
- Red blood cell enzyme levels: galactokinase and gal-1-uridyltransferase as part of galactosemia workup
- Karyotype: in conjunction with genetic consultation and ocular examination of parents and siblings

Imaging

Ophthalmologist may perform ocular ultrasonography if unable to visualize structures posterior to the opacity.

Diagnostic Procedures/Other

- Complete, timely ophthalmic evaluation by a pediatric ophthalmologist, including slit-lamp biomicroscopy and dilated fundus examination
- Examination under anesthesia may be required if office-based exam is inadequate. Coupled with intent to remove cataract when necessary.

DIFFERENTIAL DIAGNOSIS

- Childhood cataracts can be readily identified as such. However, they represent one of the many etiologies on the differential diagnosis for leukocoria.
- Cataracts may also be an expression of an underlying systemic disease, which must be diagnosed for the child's overall benefit.
- Leukocoria or poor red reflex differential diagnosis:

- Retinoblastoma
- Retinopathy of prematurity
- Persistent fetal vasculature
- Uveitis
- Retinal detachment
- Coats disease
- Toxocariasis

TREATMENT

ADDITIONAL TREATMENT

General Measures

- Importance of timely referral:
 - Congenital cataracts may require surgical removal by 4–6 weeks of age to prevent irreversible deprivation amblyopia, so quick referral is critical.
 - Acquired pediatric cataracts may also cause amblyopia, typically prior to 7 years of age.
- Conservative management:
 - Partial cataracts that do not block the visual axis may be managed with observation, pharmacologic pupillary dilatation, and/or amblyopia treatment as needed (occlusion of the contralateral eye). Glasses may or may not be of additional help.
 - A small or partial cataract may progress, so close follow-up is required.

SURGERY/OTHER PROCEDURES

- Visually significant cataracts must be removed surgically. An intraocular lens (IOL) may be inserted at the time of cataract surgery or later when the child is older.
- Successful intervention must occur very early in life in the case of visually significant congenital cataracts or as soon as possible after progression of later onset or partial cataracts.
- To prevent deprivation amblyopia in bilateral cases, both cataracts are typically removed within 1 or 2 weeks of each other. Rarely the eyes

are operated simultaneously, if anesthesia risks are high.

- Postoperative care
 - Overview: Removing the lens leaves the child aphakic (without a lens). Postoperative optical correction with contact lens, glasses, and/or IOL and amblyopia treatment are essential for optimal visual prognosis.
 - Contact lens: In children <1 year of age, optical correction of aphakia is frequently accomplished with contact lenses or spectacles. An IOL is sometimes placed initially but more often is implanted after eye growth as a secondary procedure.
 - IOL: In children >1 year of age, IOLs are frequently placed at the time of cataract surgery. Glasses are needed as well, even when an IOL is placed.
 - Amblyopia therapy: In unilateral cataract cases, successful visual rehabilitation usually requires aggressive occlusion therapy to the normal eye, possibly for years.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Without treatment, visually significant cataracts result in progressive visual loss. When an opacity that is present at birth or very early in life is not promptly addressed, the visual loss quickly becomes irreversible.
- Once surgical removal is performed and optical correction is started, the child, the parents, and the ophthalmologist enter into an intensive and long rehabilitation period, lasting until visual maturity is reached (usually 7–10 years of age). Afterward, yearly eye examinations remain a minimum requirement.
- Parental and educational support services as well as special local, state, and federal services for the visually handicapped and blind may be required as not all children with successful surgical results will have good vision.

ALERT

Pitfalls include (i) lack of early diagnosis, referral, and treatment; (ii) lack

of understanding of irreversible deprivation amblyopia; (iii) lack of adherence with postoperative optical correction and occlusion therapy; and (iv) lack of continued long-term follow-up to detect and treat late glaucoma or shift in refractive errors with continued eye growth.

PROGNOSIS

- Early surgery and rapid postsurgical optical correction result in best corrected visual acuities of 20/40–20/200 for monocular cataracts and 20/40 or better for bilateral cataracts. 20/20 is obtained in some patients.
- With dense unilateral cataracts, good vision is obtained if the surgery is completed within the first 6 weeks of life. After this time, visual restoration becomes progressively more difficult because of deprivation amblyopia.
- The prognosis for visual rehabilitation in children with bilateral congenital cataracts is better than for unilateral, as long as treatment is before vision deprivation nystagmus develops.
- Later onset and partial, slowly progressing cataracts have the best prognosis.
- Family adherence with both postsurgical optical correction and amblyopia treatment is critical and directly affects the child's ultimate visual outcome later in life.

COMPLICATIONS

- Lack of removal of a visually significant cataract at the appropriate time leads to irreversible deprivation amblyopia.
- Cataract removal in children leaves the eye without the natural crystalline lens—a structure that normally changes to offset the effects of eye growth. Even when an IOL is placed, glasses are often needed and these change frequently as the eyes grow. Unless appropriate optical correction is maintained, irreversible refractive amblyopia may still occur after the cataract is removed, particularly if the cataract is unilateral.
- Congenital cataract eyes often have immature outflow (trabecular meshwork) and 30% or more will eventually develop glaucoma (often years after surgery), requiring drops or surgery to control eye pressure.

- Short- and long-term postoperative complications also include visual axis opacification, retinal detachment, and, very rarely, endophthalmitis (intraocular infection). These complications may lead to vision loss or loss of the eye, and long-term ophthalmology follow-up is required.

CODES

ICD10

- H26.9 Unspecified cataract
- Q12.0 Congenital cataract
- H26.40 Unspecified secondary cataract

FAQ

- Q: Is surgical removal of the cataract a visual cure?
- A: No. Surgery is only the beginning of treatment, which also includes optical correction and amblyopia therapy.
- Q: Once the cataract is removed, will intensive, extensive follow-up be

needed?

- A: Yes. The visual prognosis is directly related to postsurgical treatment compliance.
- Q: Is the cataract easier to treat when the child is older?
- A: No. Irreversible deprivation amblyopia develops as the child grows, precluding any chance for normal vision. In newborns, cataracts must typically be removed at 4–6 weeks of age.

CAT-SCRATCH DISEASE

Camille Sabella

BASICS

DESCRIPTION

Cat-scratch disease (CSD) is a zoonotic infection caused by *Bartonella henselae*, which most commonly causes a subacute, regional lymphadenitis syndrome but is also more rarely associated with visceral organ, neurologic, and ocular manifestations.

EPIDEMIOLOGY

- Domestic cat is the primary reservoir for *B. henselae* and the major vector for transmission to humans.
- CSD most commonly results from a cat scratch or bite; flea bites are also implicated in the transmission of CSD.
- Kittens are more likely to transmit the organism than adult cats.
- 90% of patients with CSD have history of recent cat contact.
- Person-to-person transmission is not thought to occur.
- More common in males
- Most cases of CSD occur in the fall and winter.

Incidence

- There are ~22,000 cases each year; annual incidence of CSD is 3.7/100,000 persons.
- Most cases occur in those <21 years of age. Children younger than 10 years of age have highest age-specific annual attack rate (9.3/100,000).
- Most common cause of subacute/chronic regional lymphadenitis in U.S. children

GENERAL PREVENTION

- Avoiding cats is an effective, but impractical, method of preventing CSD; declawing cats can also be considered.
- Cat bites and scratches should be immediately and thoroughly cleaned.
- Immunocompromised individuals should avoid contact with cats that scratch or bite and avoid kittens as new pets.

- Care of cats should involve effective flea control.

PATHOPHYSIOLOGY

- Infection can result in local invasion, causing lymphadenopathy, or disseminated infection, leading to visceral organ spread.
- Involved nodes initially develop generalized lymphoid hyperplasia, followed by the development of stellate granulomas; the centers are acellular and necrotic and may be surrounded by histiocytes and peripheral lymphocytes.
- Progression leads to microabscesses, which may become confluent and lead to pus-filled pockets within the infected nodes.

ETIOLOGY

The etiologic agent is *B. henselae*, a fastidious, small, curved, pleomorphic gram-negative bacillus.

DIAGNOSIS

HISTORY

- Cat contact
 - 90% of patients have an antecedent cat contact.
- A skin rash
 - A red papule generally appears on the skin at the site of inoculation 7–12 days after the initial cat scratch.
 - This papule persists for 1–4 weeks, often progresses through a vesicular and crusty stage, and then regresses spontaneously.
- Appearance of large lymph nodes
 - Within 1–4 weeks after appearance of a skin lesion, lymphadenopathy in the region of drainage (generally immediately proximal to the skin lesion) is often noted.
- Other symptoms
 - Most persons with CSD do not have fever or other constitutional symptoms; fever and mild systemic symptoms (such as generalized achiness, malaise, and anorexia) are present in up to 30% of patients.

PHYSICAL EXAM

- An erythematous papule at the inoculation site may be detectable.
- Chronic or subacute lymphadenitis involving the 1st or 2nd set of nodes draining the inoculation site is present in approximately 90% of cases:
 - The groups affected, in decreasing order of frequency, are the axillary, cervical, submandibular, periauricular, epitrochlear, femoral, and inguinal lymph nodes.
 - Affected nodes are usually tender, with overlying erythema, warmth, and induration.
 - ~10–30% spontaneously suppurate or form a sinus tract to the skin.
- The finding of conjunctivitis/conjunctival granuloma along with ipsilateral preauricular lymphadenitis is a unique presentation of CSD (Parinaud oculoglandular syndrome), in which the conjunctiva or eyelid is the site of inoculation.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Indirect fluorescence antibody (IFA) testing
 - For detection of serum antibodies to *B. henselae*
 - Available at many commercial laboratories and the Centers for Disease Control and Prevention
 - Can be used to confirm CSD
 - A single IgG titer of $\geq 1:512$, a 4-fold rise in titer, or seroconversion is necessary for serologic diagnosis of CSD.
 - IgM titers are less sensitive than IgG titers, even in acute disease.
 - Overall sensitivity and specificity of IFA IgG testing is 88% and 98%, respectively.
- Enzyme immunoassay (EIA) testing
 - Also for detection of serum antibodies to *B. henselae*
 - Similar sensitivity and specificity to IFA
- Blood cultures
 - Using lysed or centrifuged blood may, at times, yield *B. henselae* growth from infected individuals in whom bacteremia is suspected.
 - Growth typically is obtained on blood agar after 12–15 days but may require incubation period of up to 45 days.

- Polymerase chain reaction (PCR)
 - Available in some commercial and research laboratories
 - Sensitive and specific method for diagnosis of Bartonella infection in tissue specimens (e.g., needle aspiration of lymph node)
- Histologic findings of lymph nodes are characteristic of CSD but not pathognomonic.
 - Early findings include lymphocytic infiltration with epithelioid granulomas.
 - Later findings include neutrophilic infiltration with necrotic granulomas (stellate microabscesses).
- Warthin-Starry silver stain
 - May demonstrate *B. henselae* bacilli in chains, clumps, or filaments within necrosed areas of lymph node or within primary inoculation site of the skin
 - Not specific for *B. henselae* and not definitively diagnostic of CSD but is strongly suggestive in conjunction with compatible clinical findings

DIFFERENTIAL DIAGNOSIS

- Includes infectious and noninfectious causes of lymphadenopathy
 - Mycobacterial infection (*Mycobacterium tuberculosis* and non-tuberculous mycobacterial infection)
 - Malignancy, especially lymphoma
 - Acute bacterial lymphadenitis caused by *Staphylococcus aureus* and *Streptococcus pyogenes*)
 - Tularemia
 - Viral causes of lymphadenopathy such as EBV, CMV, or HIV
 - Toxoplasmosis

TREATMENT

MEDICATION

- Antimicrobial therapy may hasten recovery in acutely or severely ill patients with systemic symptoms and is recommended for all immunocompromised people.

- Macrolides, doxycycline, ciprofloxacin, and trimethoprim-sulfamethoxazole appear to be effective.
- Rifampin may be effective but is often used in combination with a macrolide or doxycycline.
- Azithromycin or doxycycline is recommended for patients with bacillary angiomatosis and bacillary peliosis.
- The optimal duration of therapy for complicated infections is not clear but may be prolonged for systemic disease.
- Azithromycin (500 mg initially then 250 mg daily for a total of 5 days in patients >45.5 kg and 10 mg/kg on the 1st day and 5 mg/kg for the subsequent 4 days in patients ≤45.5 kg) has been shown to be of modest clinical benefit in children with uncomplicated CSD and is recommended by some experts.

ADDITIONAL TREATMENT

General Measures

- The management of typical CSD is supportive.
- Many experts suggest conservative, symptomatic treatment only, except in severe or systemic disease or in immunocompromised patients.

ISSUES FOR REFERRAL

- Consider infectious disease consult to aid in evaluation, diagnosis, and management, especially in complicated disease or in immunocompromised hosts.
- Consider general surgery consult for needle aspiration if needed.

SURGERY/OTHER PROCEDURES

- Percutaneous needle aspiration of painful, fluctuant nodes can be performed for relief of pain.
- Incision and drainage should be avoided to reduce the risk of sinus tract formation, and surgical excision is generally not necessary.

INPATIENT CONSIDERATIONS

Admission Criteria

- Severe pain refractory to oral analgesics
- Workup to rule out serious other causes of lymphadenopathy or

symptomatology

- Severe or unusual complications of CSD

Discharge Criteria

- Pain under adequate control
- No concern for serious or life-threatening complications or other disorders requiring further evaluation or treatment

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Typical CSD is self-limited. Slow resolution of enlarged or painful lymph nodes will occur over 2–4 months.
- ~10–30% of affected lymph nodes will spontaneously suppurate.

PROGNOSIS

- Most immunocompetent patients have a benign course with complete recovery.
- Patients with significant complications, such as encephalopathy, thrombocytopenic purpura, or bone lesions, usually have a more prolonged course but generally have a good long-term prognosis.

COMPLICATIONS

- Systemic CSD
 - Usually characterized by fever, arthralgia, malaise, myalgia, and hepatosplenic involvement
 - Cause of fever of unknown origin (FUO) in children
 - Hepatosplenic involvement may manifest with abdominal pain; microabscesses or granulomas may be visualized on ultrasound or CT of the liver and spleen.
- Encephalopathy/encephalitis
 - May occur 1–3 weeks after the initial symptoms of CSD
 - Seizures, lethargy, combative behavior, and coma may occur.
 - CSF analysis typically normal or slight lymphocytic pleocytosis and elevated protein
 - Recovery is generally complete.

- Optic neuritis or neuroretinitis
 - Acute (usually unilateral) painless vision loss
 - Associated with stellate macular exudates
- Erythema nodosum
 - Likely represents a delayed hypersensitivity reaction to the infection
 - Most often involves the subcutaneous fat of the legs and, at times, dorsum of arms, hands, and feet
- Osteolytic bone lesions
- Endocarditis
- Other, rare complications
 - Thrombotic thrombocytopenic purpura
 - Henoch-Schönlein purpura
 - Mesenteric lymphadenitis
 - Pneumonia
 - Osteomyelitis
 - Hypercalcemia
 - Guillain-Barré syndrome
 - Transverse myelitis
- Endocarditis
- Bacillary angiomatosis and bacillary peliosis can occur in the immunocompromised host.

CODES

ICD10

A28.1 Cat-scratch disease

FAQ

- Q: Can a sibling develop CSD from an infected patient?
- A: No. There is no evidence of person-to-person transmission. However, asymptomatic household contacts of the index case are more likely to be seropositive than the general population, likely related to exposure to the same animal.
- Q: Should the parents of a child with CSD get rid of the cat?
- A: In general, this is not recommended. These animals are not ill; the capacity to transmit disease appears to be transient, and recurrent disease is rare.
- Q: What is the benefit of azithromycin in the treatment of uncomplicated CSD lymphadenitis?
- A: In a prospective, randomized, double-blind study, azithromycin given for 5 days was shown to result in significantly greater decrease in lymph node volume during the 1st month of treatment as compared to placebo. However, there was no difference in outcome between the 2 groups after 30 days.

CAVERNOUS SINUS SYNDROME

Daphne M. Hasbani • Sabrina E. Smith

BASICS

DESCRIPTION

- Cavernous sinus syndrome comprises disease processes that localize to the cavernous sinus—a venous plexus that drains the face, mouth, tonsils, pharynx, nasal cavity, paranasal sinuses, orbit, middle ear, and parts of the cerebral cortex.
- Small lesions in this region may produce dramatic neurologic signs.

EPIDEMIOLOGY

Cavernous sinus syndrome is a rare but serious condition.

PATHOPHYSIOLOGY

- The cavernous sinus is located lateral to the pituitary gland and sella turcica, superior to the sphenoid sinus, and inferior to the optic chiasm.
- Within the cavernous sinus are the carotid artery, the pericarotid sympathetic fibers, and the abducens nerve (VI); within its lateral wall are the oculomotor nerve (III), the trochlear nerve (IV), and the ophthalmic and maxillary divisions of the trigeminal nerve (V1, V2).
- Cavernous sinus syndrome is typically caused by septic or aseptic sinus thrombosis, neoplasm, or trauma. Acute obstruction by mass or thrombosis may progress rapidly if not diagnosed and treated quickly.

ETIOLOGY

- Infectious agents include *Staphylococcus aureus*, *Streptococcus pneumoniae*, Gram-negative rods, and anaerobes; Mucormycosis and *Aspergillus* in immunocompromised patients.
- Aseptic venous thrombosis has been associated with sickle cell anemia, trauma, dehydration, vasculitis, pregnancy, oral contraceptive use, congenital heart disease, inflammatory bowel disease, and hypercoagulable states.
- Neoplasms involving the cavernous sinus include pituitary adenomas,

meningiomas, trigeminal schwannomas, craniopharyngiomas, lymphomas, neuromas, chordomas, chondrosarcomas, rhabdomyosarcomas, nasopharyngeal carcinomas, and very rarely, teratomas. Neoplasms may present with diplopia, visual field deficits, headache, or isolated cranial nerve deficits.

- The lateral extension of pituitary neoplasms into the cavernous sinus usually affects the 3rd cranial nerve, with the 4th and 6th nerves less commonly involved. Rupture of a cystic craniopharyngioma may present as acute cavernous sinus syndrome.
- Carotid-cavernous fistulas, often with a more chronic course, are direct high-flow shunts between the internal carotid artery and the cavernous sinus. Most often sequelae of trauma, they may present with a history of ocular motility deficits, arterialization of conjunctival vessels, and a bruit usually heard best over the orbit. Less commonly, rupture of a carotid cavernous aneurysm may lead to fistula formation.
- Nonspecific and idiopathic inflammation of the cavernous sinus, also called idiopathic cavernous sinusitis or Tolosa-Hunt syndrome, has been reported in patients as young as 3½ years. This is a diagnosis of exclusion. However, MRI may show enlargement of the affected cavernous sinus with an adjacent soft tissue mass that resolves after treatment with steroids.

DIAGNOSIS

HISTORY

- Recent facial furuncle or cellulitis, sinusitis, dental infection, otitis, or orbital cellulitis may predispose to cavernous sinus syndrome.
- Fever, headache, eye pain, diplopia, and facial paresthesias may be present.

PHYSICAL EXAM

- Conjunctival injection with lid swelling and proptosis indicates cavernous sinus venous congestion.
- Ptosis, anisocoria, ophthalmoparesis, and facial sensory changes are signs of cranial nerve involvement.

- Horner syndrome: Sympathetic nerve fibers traveling with V1 may be affected. Usually occurs in conjunction with an abducens nerve (CN VI) palsy with an inability to abduct the eye.
- Signs and symptoms begin unilaterally but may rapidly spread bilaterally.
- The optic nerve and visual acuity are spared early in cavernous sinus syndrome but can be affected as it progresses.
- Funduscopy findings include venous dilatation and hemorrhages.
- Ocular bruit may be heard in any acute cavernous sinus syndrome but especially in carotid-cavernous fistula.
- Signs of meningitis and systemic toxicity rapidly evolve if infections are untreated.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- CBC, ESR, PT/PTT, blood culture: Basic studies in any child with suspected acute cavernous sinus syndrome. Blood cultures are positive in 70% of cases of septic venous sinus thrombosis.
 - Lumbar puncture should be performed if there is no contraindication and infection is suspected.
 - ~35% of patients with septic cavernous sinus thrombosis have CSF findings consistent with bacterial meningitis—excess neutrophils, increased protein, and/or decreased glucose.
- Evaluation for a prothrombotic state should be considered in patients with cavernous sinus thrombosis, especially in the absence of infection or trauma. Specific labs include protein C activity, protein S activity, antithrombin III activity, factor V Leiden gene mutation, prothrombin gene mutation, anticardiolipin antibodies, β -2-glycoprotein antibodies, dilute Russell viper venom time, homocysteine, lipoprotein(a), and factor VIII activity.
- Antinuclear antibody panel, angiotensin-converting enzyme level, and HIV test should be obtained before diagnosis of Tolosa-Hunt syndrome (diagnosis of exclusion).

Imaging

Any child with proptosis, cranial nerve findings, or an ocular bruit should

have an urgent MRI or CT.

- MRI, with and without gadolinium, with special attention to the cavernous sinus and parasellar region, is the imaging study of choice.
- Magnetic resonance venography may be helpful.
- CT angiography may be the preferred study to evaluate for carotid-cavernous fistula.

Diagnostic Procedures/Other

- Diagnosis of carotid-cavernous fistulas requires angiography.
- Nasopharyngeal biopsy and culture if Mucormycosis or Aspergillus is suspected.

DIFFERENTIAL DIAGNOSIS

Other disorders that may resemble cavernous sinus syndrome include the following:

- Orbital cellulitis
- Sphenoid sinusitis
- Thyroid eye disease
- Cavernous carotid aneurysm
- Orbital apex tumor
- Orbital pseudotumor
- Ocular migraine
- Ocular trauma
- Burkitt lymphoma

ALERT

- Ophthalmoplegic migraine or cluster headache must be distinguished from cavernous sinus syndrome by neuroimaging studies and history.
 - Proptosis does not occur in migraine or cluster headache.
 - Ophthalmoplegic migraine is a diagnosis of exclusion, especially on first presentation.
- Acute infection and hemorrhage of the pituitary gland—pituitary apoplexy—may present with acute bilateral ophthalmoplegia and signs of acute pituitary insufficiency; most commonly occurs with pituitary neoplasms but may also occur in pregnant women at the time of delivery.
- Chronic granulomatous disorders such as sarcoid and tuberculosis may

underlie cavernous sinus syndrome.

TREATMENT

First priority is to rule out septic cavernous sinus thrombosis, life-threatening infections of the face, sinuses, middle ear, teeth, and orbit.

MEDICATION

First Line

- For septic cavernous sinus thrombosis, broad-spectrum antibiotics (including coverage of penicillinase-resistant staphylococci and anaerobes) are begun immediately. Duration of therapy is usually 2–4 weeks beyond the resolution of symptoms.
- Amphotericin B if Mucormycosis or Aspergillus is suspected
- Idiopathic cavernous sinusitis, a diagnosis of exclusion, responds to corticosteroids. Treatment should not be started until neoplasm and infection have been ruled out.

Second Line

Anticoagulation is controversial, but one study in adults found that heparin reduced morbidity from septic cavernous sinus thrombosis.

SURGERY/OTHER PROCEDURES

- Surgical drainage of the primary infection (i.e., sinusitis) may be indicated (avoiding surgical manipulation of the cavernous sinus itself).
- Posttraumatic carotid-cavernous fistulas rarely close spontaneously and have been treated with endoarterial balloon embolization.

ONGOING CARE

- Septic cavernous sinus thrombosis may relapse or embolic abscesses may develop 2–6 weeks after therapy has been stopped.
- Repeat MRI with gadolinium should be considered, especially if symptoms recur or new symptoms develop.

- Mortality remains 13–30%, and <40% of patients recover fully from cranial nerve deficits.
- Patients with carotid-cavernous fistulas frequently have persistent cranial nerve deficits even after embolization.
- Idiopathic cavernous sinusitis responds to steroids, but relapses can be problematic. Clinical follow-up and serial MRI scans are indicated to rule out a low-grade neoplasm or fungal infection.
- Consultation with a neurooncologist and a neurosurgeon is important for suspected neoplasms or surgical lesions.

PROGNOSIS

- Prognosis depends on the underlying cause.
- Bacterial infections usually respond if diagnosed and treated promptly.

COMPLICATIONS

- Vary with the cause of cavernous sinus syndrome. Septic cavernous sinus syndrome thrombosis and fungal infections may rapidly evolve to bilateral thrombosis, life-threatening sepsis, and meningitis.
- Visual impairment and cranial nerve palsies may persist.
- Mucormycosis, usually seen in patients with diabetic ketoacidosis, is especially dangerous.
- Carotid arteritis with resulting stenosis, occlusion, or embolism may occur, resulting in focal neurologic deficits.
- Aseptic cavernous sinus syndrome thrombosis may evolve to more extensive intracranial venous sinus thrombosis.
- Local spread of neoplasms will continue if not treated appropriately.

CODES

ICD10

- I67.6 Nonpyogenic thrombosis of intracranial venous system
- G08 Intracranial and intraspinal phlebitis and thrombophlebitis
- H49.889 Other paralytic strabismus, unspecified eye

FAQ

- Q: Will my child's eye movements return to normal?
- A: In most cases, oculomotor nerves regain function as other signs improve, although they may take the longest to recover.
- Q: Can more pain medicine be given?
- A: There is often an attempt to balance side effects of sedation and hypoventilation against the need for pain control, especially when intracranial pressure is a concern.

CAVERNOUS TRANSFORMATION AND PORTAL VEIN OBSTRUCTION

Vani V. Gopalareddy

BASICS

DESCRIPTION

- Cavernous transformation: the collection of collaterals that develop around an obstructed vessel
- Portal vein obstruction
 - Can occur anywhere along the course of the main portal vein or splenic vein, between the hilum of the spleen and the porta hepatis
 - In pediatrics, obstruction is most typically of the portal vein.
- Major cause of prehepatic portal hypertension

EPIDEMIOLOGY

- Most children with portal vein thrombosis present between birth and 15 years of age.
- Acute presentation is rare.
- Chronic cases present with complications of portal hypertension.
- Gastrointestinal (GI) bleeding is more typical in patients presenting <7 years of age.
- Splenomegaly in the absence of symptoms is more typical for patients aged 5–15 years.

RISK FACTORS

Genetics

A genetic basis of this problem has not been identified, although congenital abnormalities of the heart, major blood vessels, biliary tree, and renal system are often found.

PATHOPHYSIOLOGY

- In cirrhosis and hepatic malignancies, the thrombus usually begins intrahepatically and spreads to the extrahepatic portal vein.
- In most other etiologies, the thrombus usually starts at the site of origin

of the portal vein.

- Occasionally, thrombosis of the splenic vein propagates to the portal vein, most often resulting from an adjacent inflammatory process (e.g., severe pancreatitis).
- Asymptomatic splenomegaly or upper GI hemorrhage results from extrahepatic portal hypertension.
- Less commonly, ascites or failure to thrive, and portopulmonary hypertension

ETIOLOGY

50% of portal vein obstructions are idiopathic. Identified causes include the following:

- Congenital vascular anomaly
 - Portal vein malformation
 - Webs or diaphragms within the portal vein
- Clot resulting from a hypercoagulable state
- Clot from other causes:
 - Omphalitis
 - Umbilical vein catheterization
 - Portal pyelophlebitis
 - Intra-abdominal sepsis
 - Surgery near the porta hepatis
 - Sepsis
 - Cholangitis
 - Dehydration
 - Trauma
- Other causes for portal vein obstruction in older children:
 - Ascending pyelophlebitis from perforated appendicitis
 - Primary peritonitis, cholangitis, and pancreatitis causing a splenic vein thrombosis
 - Inflammatory bowel disease

DIAGNOSIS

HISTORY

- Splenomegaly (see “[Splenomegaly](#)” topic for complete differential)
 - Exposure to infectious mononucleosis
 - Metabolic storage disease (e.g., Gaucher disease)
 - Malignancy (e.g., chronic myelogenous leukemia)
- History of prematurity and admission to NICU should alert the clinician to previous umbilical vein catheterization and increased risk of portal vein thrombosis.

SIGNS AND SYMPTOMS

- Clinical history and examination should concentrate on identifying possible causes predisposing to portal vein obstruction.
- Portal vein obstruction does not affect liver function unless the patient has an underlying liver disease (e.g., cirrhosis). This situation is partially due to a compensatory increased flow of the hepatic artery maintaining the total hepatic blood flow.
- Mild coagulation profile abnormalities

PHYSICAL EXAM

- Splenomegaly
 - Spleen is measured from the left anterior axillary line at the costal margin diagonally toward the umbilicus and inferiorly toward the iliac crest
- Hemorrhoids

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- CBC: Leukopenia and thrombocytopenia will be present if there is hypersplenism.
- Aspartate aminotransferase/alanine aminotransferase/γ-glutamyl transferase: should be normal
- PT/PTT: may be abnormal if malabsorption is present
- Additional testing associated with hypercoagulable states (as clinically indicated)
 - Protein C
 - Protein S
 - Antithrombin III levels
 - Factor V Leiden mutation

- Activated protein C resistance
- Lupus anticoagulation evaluation
- Anticardiolipin antibodies (IgA, IgG, IgM)
- Antinuclear antibody
- Blood homocysteine
- Prothrombin 20-21-0 mutation
- Methylene tetrahydrofolate reductase mutation evaluation
- Factor VIII coagulant
- Reptilase time
- Heparin cofactor II
- Tissue plasminogen activator
- Plasminogen activator inhibitor-1
- Sticky platelet evaluation
- Paroxysmal nocturnal hemoglobinuria (genetics or flow cytometry evaluation)

Imaging

- Ultrasound with Doppler
 - To examine portal vein flow and to identify collateral veins if there is cavernous transformation of the portal vein
 - Liver may be slightly small but may be normal in texture.
 - Remains the most useful imaging study
- CT angiography or MRV can give additional information if needed especially prior to planning a surgical portosystemic shunt procedure.

Diagnostic Procedures/Other

- Liver biopsy
 - Not required for diagnosis nor performed routinely
 - Exclude other etiologies
- Upper endoscopy and sigmoidoscopy: to define extent of varices

Pathologic Findings

- Portal hypertension: spider nevi, prominence of abdominal veins, splenomegaly
- Bruising: may be prominent when coexistent consumption of clotting factors
- Normal liver palpation and percussion

- Ascites rarely present

DIFFERENTIAL DIAGNOSIS

The differential diagnosis must exclude other causes of splenomegaly and portal hypertension.

TREATMENT

ADDITIONAL TREATMENT

General Measures

- General goals of therapy are (1) to manage variceal hemorrhage and (2) to identify an underlying cause and/or determine if the patient is at risk for additional venous thrombosis or malignancy.
- Therapy for GI variceal hemorrhage:
 - Octreotide infusion: 1 mcg/kg/h maximum 50 mcg/h
 - Prophylactic variceal banding for large esophageal varices
 - β -Blocker therapy
 - Rex shunt (mesenterico–left intrahepatic portal vein shunt):
 - Can be surgically addressed using the internal jugular vein, internal iliac vein, or dilated coronary vein, which is used to connect the superior mesenteric vein and the umbilical portion of the left portal vein (in the liver)
 - Restores the physiologic intrahepatic portal vein perfusion
 - Avoids the consequences of long-term portosystemic shunting, especially hepatic encephalopathy
- Portosystemic shunts: divert portal blood into the low-pressure systemic venous circulation. Classified into
 - Nonselective shunts: These communicate the entire portal venous system to a systemic venous circulation such as the mesocaval shunt, proximal splenorenal shunt, and portacaval shunts. Nonselective shunts divert more blood into the systemic venous system, and patients are more likely to have encephalopathy.
 - Selective shunts: These divert the gastrosplenic portion of the portal venous flow into the left renal vein or the inferior vena cava. The most common selective shunt is the distal splenorenal shunt (also

known as the Warren shunt).

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Focus on growth parameters, early detection of malabsorption, presence of GI hemorrhage, and nutritional intervention.

- Aggressive contact sports should be actively discouraged in children with hepatosplenomegaly.
- All patients should be advised to restrict activities that could injure their already enlarged spleen. Spleen guards may be recommended.
- Patients should be told to avoid medicines that interfere with platelet function
- In addition, patients should avoid medications that increase BP, including many over-the-counter cold medications (e.g., phenylephrine), as this can increase splanchnic pressures and may provoke variceal bleeds.

PROGNOSIS

- Long-term prognosis overall is considered good.
- Upper GI hemorrhage becomes less problematic as children become older.
- Rex shunt restores normal physiology and decreases portal pressure. In many centers, Rex shunt is performed as 1st-line therapy.
- Most patients receive β -blockers or undergo prophylactic banding. If the liver function remains normal, as in most cases, it is rare for encephalopathy to develop unless a large portosystemic shunt is created.

COMPLICATIONS

- Variceal hemorrhage from the upper tract or from the perianal varices
- Splenomegaly with hypersplenism
 - Thrombocytopenia
 - Consumption coagulopathy
 - Leukopenia
- Steatorrhea and protein-losing enteropathy occurs secondary to venous

congestion of the intestinal mucosa.

- Degree of portal hypertension is variable and depends on the formation of spontaneous shunts that may decompress the portal hypertension. These autoshunts may predispose to the development of complications such as hepatic encephalopathy or hepatopulmonary syndrome.
- Spleen can undergo autoinfarction, resulting in intermittent episodes of pain.
- A large spleen is susceptible to traumatic rupture.
- Spontaneous splenic rupture may also occur (classically associated with infectious mononucleosis).

- Q26.9 Congenital malformation of great vein, unspecified

FAQ

- Q: Should I restrict my child's activities and avoid certain medications?
- A: Contact sports should be limited or a spleen guard should be used. NSAIDs, including aspirin, should be avoided because of the risk of hemorrhage. Medications that increase blood pressure, including many nonprescription cold preparations, should also be avoided.

CELIAC DISEASE

Dascha C. Weir

BASICS

DESCRIPTION

- Celiac disease (CD) is a systemic immune-mediated disorder caused by a permanent sensitivity to gluten in genetically susceptible individuals.
- “Gluten” is the collective term for specific alcohol-soluble proteins (called prolamines) that are found in wheat, rye, and barley.
- “Classic CD” refers to children who present predominately with malabsorptive symptoms including diarrhea, abdominal pain, vomiting, and abdominal distention in the setting of suboptimal growth and irritability.
- “Silent CD” defines a minority of people with CD who have no identifiable symptoms but have consistent intestinal mucosal lesions and elevated serum antibodies.
- A rare, but serious, manifestation of CD is termed “celiac crisis” and consists of severe watery diarrhea, electrolyte disturbances, dehydration, hypotension, and lethargy.
- Patients with positive serologic testing but normal intestinal histology are referred to as “potential CD.” Some, but not all, of these patients are thought to develop CD overtime on a gluten-containing diet.

PATHOPHYSIOLOGY

- In people with CD, ingestion of gluten leads to an enteropathy of the small intestine characterized by mucosal inflammation and villous atrophy.
- Generation of unique serologic autoantibodies and development of a diverse spectrum of signs and symptoms also occur.
- Elimination of gluten, via implementation of a strict gluten-free diet (GFD), leads to intestinal healing, normalization of elevated antibody levels, and resolution of related symptoms.

EPIDEMIOLOGY

- CD is present in approximately 1% of the U.S. population, but only a small proportion have been diagnosed.
- Average age at diagnosis of pediatric CD in the United States is approximately 9 years old.
- Females are more affected than males.

Genetics

- There is increased prevalence in patients with 1st-degree relatives with CD (10–15%).
- HLA-DQ2 and HLA-DQ8 haplotypes are “necessary but not sufficient” for CD.
 - 90+% of CD patients carry HLA DQ2, 5% carry HLA-DQ8.
 - High negative predictive value for negative DQ2/DQ8 testing
 - Low positive predictive value (30% of general population in North America is HLA-DQ2 positive)
- Numerous other genes have been identified as increasing CD susceptibility.
- A family or personal history of autoimmune disease is also associated with CD.

COMMONLY ASSOCIATED CONDITIONS

- Autoimmune thyroiditis
- Type 1 diabetes mellitus
- Sjögren syndrome
- Selective IgA deficiency
- Williams syndrome
- Down syndrome
- Turner syndrome

DIAGNOSIS

- The range of signs and symptoms secondary to CD is broad. Malabsorptive symptoms such as diarrhea and weight loss are more commonly seen in early childhood. Other more subtle gastrointestinal (GI) symptoms in pediatric CD can be recurrent intermittent abdominal pain, intermittent diarrhea, constipation, and nausea.

- Extraintestinal manifestations of CD may be more prominent, especially in the older child. Atypical” or “nonclassic” symptoms can include the following:
 - Aphthous stomatitis
 - Arthritis/arthralgias
 - Delayed puberty
 - Dental enamel hypoplasia
 - Dermatitis herpetiformis (a pruritic blistering symmetric rash)
 - Elevated transaminases
 - Elevated pancreatic enzymes
 - Fatigue
 - Iron deficiency anemia
 - Neuropsychiatric symptoms (including headaches, cognitive impairment, neuropathy, epilepsy and ataxia)
 - Osteopenia
 - Short stature
 - Thyroiditis
 - Vitamin deficiencies
- Awareness of the wide range of clinical presentation and the high prevalence of CD coupled with a careful history and physical exam is essential to making the diagnosis of CD.
- Obtaining celiac-specific serologic markers is also integral to making the diagnosis.
- Currently, small bowel biopsies remain the gold standard and are required for confirmation of CD.
- Treatment with a GFD should not be initiated before confirmation of disease.

HISTORY

- Review the patient’s stooling pattern as well as symptoms of abdominal pain, nausea/ vomiting, low appetite, and bloating/distension.
- Investigate extraintestinal manifestations of CD including fatigue, arthralgias, recurrent oral sores, unusual rashes, and headaches.
- Attention to family history of CD, long-standing undiagnosed GI symptoms, and autoimmune diseases

PHYSICAL EXAM

- Focus on growth patterns:
 - Some patients may have short stature or suboptimal weight gain as the only manifestation of CD.
 - Many children with CD have normal growth or even overweight status.
- Assess pubertal development.
- Although patients with classic CD often have a distended abdomen with wasted buttocks, most patients do not have clear physical signs of CD.
- Observe for dental enamel defects, oral sores, or dermatitis herpetiformis.

DIAGNOSTIC TESTS & INTERPRETATION

All evaluation for CD should be done while a patient is consuming gluten regularly. Testing for the disease while on a GFD can lead to false-negative results. Both serologic testing and histopathologic changes can normalize with gluten removal.

Initial Lab Tests

- Total IgA quantification is essential. IgA deficiency is associated with CD and can contribute to false-negative results.
- Celiac serologic markers with high specificity and sensitivity
 - Tissue transglutaminase antibody IgA (tTG IgA): best general screening test
 - Endomysial antibody IgA (EMA IgA): more subjective and expensive than tTG IgA
- Celiac serologic markers with low specificity and sensitivity
 - Antigliadin IgA and IgG (AGA IgA, AGA IgG) are NOT recommended for screening.
- New serologic markers: Deamidated gliadin peptide antibody IgG is a newer test with high sensitivity and specificity that may be useful to obtain in cases of IgA deficiency.
- Nonspecific testing to screen for associated nutritional deficiencies
 - Vitamin levels
 - CBC

- Iron panel
- Bone densitometry
- Tests of absorption (fecal fat, D-xylose uptake)

Endoscopic Evaluation

- Small bowel biopsies obtained by esophagogastroduodenoscopy (EGD) is required in most cases to confirm CD.
 - It is recommended to obtain multiple small bowel biopsies during endoscopy due to the patchy distribution of lesions.
 - The duodenal bulb, in addition to the duodenum, should be biopsied.
 - The current recommendation is to obtain a small bowel biopsy on a gluten-containing diet.

Pathologic Findings

CD has a number of cardinal histopathologic findings on small bowel biopsy:

- Increased intraepithelial lymphocytosis
- Villous atrophy (partial, subtotal, or total)
- Crypt hyperplasia
- Infiltration of lamina propria with excess lymphocytes (CD4 T cells mainly) and plasma cells

DIFFERENTIAL DIAGNOSIS

- Presumed infectious causes:
 - Giardiasis
 - Rotavirus, parasites
 - Chronic gastroenteritis
 - Postenteritis enteropathy
 - Intractable diarrhea of infancy
 - Tropical sprue
 - Intestinal bacterial overgrowth
 - Immunodeficiency syndromes (HIV)
- Presumed noninfectious:
 - Milk or soy protein intolerance
 - Protein-calorie malnutrition
 - Eosinophilic gastroenteritis

- Autoimmune enteropathy
- Graft-versus-host disease
- Collagenous sprue
- Peptic duodenitis
- Immunodeficiency syndromes
- Crohn disease
- Congenital enteropathies (microvillus inclusion disease, tufting enteropathy)
- Bowel ischemia
- Radiation
- Chemotherapy

TREATMENT

- Current treatment of CD consists of a strict, lifelong gluten-free diet (GFD).
 - Elimination of all wheat, rye, and barley is essential, with close care to avoid cross-contamination during the preparation and serving of food.
 - Oats, unless specifically certified as gluten free, should also be avoided, as they are standardly contaminated with wheat.
- Consultation with a specialized dietitian with expertise in the GFD is recommended for all cases.

MEDICATION

There are no medications currently available to treat CD. However, people on a gluten-free diet should take a multivitamin. It is imperative to confirm that all medications are also GF.

It may be appropriate to consider recommending the following:

- Calcium and vitamin D
- Iron for iron deficiency anemia
- In patients with symptoms of lactose intolerance, lactase enzyme replacement

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Close clinical monitoring of patients with newly diagnosed CD is important. Patients should be seen several times within the 1st year of diagnosis to monitor symptom response to the GFD, adherence to the GFD, and patient/family coping with the lifestyle changes associated with the GFD. After the 1st year, yearly follow-up is recommended.
- Special attention should be paid to growth at each visit. Catch-up growth is typically noted within the 1st year on the GFD.
- Monitor for other autoimmune disease, especially thyroiditis and diabetes mellitus, with targeted history and exam.
- Assessing for adequate calcium intake and vitamin D deficiency is also recommended to optimize bone health. Bone density in children with CD typically normalizes on a GFD. Bone densitometry can be considered but, in most cases, is recommended after a year on a GFD.
- tTG levels typically normalize within a year on the GFD and, coupled with clinical status, can be helpful in assessing response to the GFD. Obtaining a tTG IgA is recommended after 6 months on a GFD and then on a yearly basis.
- Repeat endoscopic evaluation is not currently recommended in patients who respond clinically to a GFD and who have normalization of tTG IgA. However, repeat endoscopic evaluation in cases of clinical nonresponse to the GFD or persistent serologic elevation should be considered.

PROGNOSIS

In patients with CD, it is strongly recommended to remain on a GFD for life. In patients on a strict GFD, there is lower risk for malignancies and other complications associated with CD. However, increased risk of other autoimmune diseases seems to persist.

COMPLICATIONS

- Adults with CD have increased risk of intestinal lymphoma and other GI malignancies. This risk is magnified in suboptimally treated CD.
- Other complications include the following:
 - Osteopenia/osteoporosis

- Infertility
- Development of other autoimmune disorders.
- Nutritional deficiencies
- Refractory CD is a diagnosis of exclusion that is defined by persistent symptoms and villous atrophy on a strict GFD.
 - Refractory CD is rare in children but affects up to 5% of adults with CD, most of whom harbor an abnormal clonal intraepithelial T-lymphocyte population
 - Complications of refractory sprue: “Cryptogenic enteropathy-associated T-cell lymphoma,” ulcerative jejunoileitis, and collagenous sprue.
 - Treatment: immunosuppressives including corticosteroids, azathioprine, cyclosporine, and total parenteral nutrition, in addition to GFD

K90.0 Celiac disease

FAQ

- Q: Is biopsy confirmation necessary if my patient is already doing better on a GFD?
- A: Yes. Referral to a pediatric gastroenterologist who can obtain small bowel biopsy is recommended in almost all cases of suspected pediatric CD.
- Q: Are oats included in the gluten-containing cereal group?
- A: Strictly speaking, wheat, rye, and barley are more closely related in their development from the primitive grains than are oat, rice, corn, sorghum, and millets, which do not activate CD. Gluten-free means a diet devoid of all wheat, rye, and barley. Several studies have shown that ingestion of oats did not cause histologic or clinical deterioration. However, it is important to use a brand of oats that has been tested and demonstrated to not be contaminated with gluten.

CELLULITIS

Nicholas Tsarouhas

BASICS

DESCRIPTION

- Cellulitis is an acute, spreading pyogenic inflammation of the dermis and subcutaneous tissue, often complicating a wound or other skin condition.
- Cellulitis may be further classified by the unique area of the body it affects (e.g., periorbital or orbital cellulitis, peritonsillar cellulitis, etc.).

EPIDEMIOLOGY

- The most common cause of cellulitis in children is *Staphylococcus aureus* or *Streptococcus pyogenes* infection, which develop secondary to local trauma of the integument.
- Community-acquired methicillin-resistant *Staphylococcus aureus* (CA-MRSA) infections continue to increase in incidence, but much more commonly cause purulent abscesses rather than cellulitis.
- The prevalence of CA-MRSA among purulent skin and soft tissue infections is >60% in some communities.
- Clinical failures caused by penicillin-resistant *Streptococcus pneumoniae* have not yet become a significant problem in cases of uncomplicated cellulitis.
- Bacteremic disease is uncommon, owing to the tremendous efficacy of vaccines against both *Haemophilus influenzae* type b (Hib) and *S. pneumoniae*.

GENERAL PREVENTION

- Good wound care is paramount.
- All wounds should be cleaned with soap and water, then covered with a clean, dry cloth.
- Topical antibiotic ointment is optional with minor wounds.

PATHOPHYSIOLOGY

- Cellulitis usually occurs after local trauma that breaches in the integument (abrasions, lacerations, bite wounds, excoriated dermatitis, varicella, etc.).
- Secondary to local invasion or infection (e.g., sinusitis leading to orbital cellulitis)
- Hematogenous dissemination (rarely)

ETIOLOGY

- *S. aureus*: methicillin-susceptible *Staphylococcus aureus* (MSSA) and MRSA
- Group A β -hemolytic streptococci (GABHS, or *S. pyogenes*)
- *S. pneumoniae* (uncommon)
- Group B streptococci (GBS) and gram-negative rods (GNRs): neonates
- Hib (rare)
- *Pseudomonas aeruginosa* and anaerobic bacteria: immunocompromised children
- *Pasteurella* species: from cat and dog bites
- *Eikenella corrodens*: from human bites

COMMONLY ASSOCIATED CONDITIONS

- Periorbital
 - Usually from local trauma (scratch, impetigo, eczema, excoriated varicella)
 - Hematogenous spread is very uncommon.
 - Rarely associated with infectious conjunctivitis
- Orbital
 - Commonly associated with severe sinusitis
 - Less commonly: dental abscess, trauma, hematogenous spread
- Buccal: usually from local trauma; hematogenous seeding also very rare.
- Peritonsillar
 - Commonly due to GABHS pharyngitis
 - Cellulitis may progress to a peritonsillar abscess.
- Extremity: usually secondary to local trauma
- Breast: usually with mastitis (neonates)
- Perianal

- Seen in infants and young children
- Etiology: GABHS
- Perianal pain, pruritus, and erythema; sometimes associated with bloody stools
- Cellulitis–adenitis syndrome
 - Neonates and infants
 - Etiology: GBS, *S. aureus*, GNRs
 - Bacteremia/meningitis commonly associated.

DIAGNOSIS

HISTORY

- An expanding, red, painful area of swelling is the most common presentation.
- Mild constitutional symptoms (with or without fever) are commonly associated with cellulitis.
- A history of local trauma to the integument is the clue to the portal of bacterial entry.
- Visual changes, proptosis, and painful or limited eye movements are classic findings in orbital cellulitis.
- Painful swallowing, pain with opening the mouth (trismus), and muffled (“hot potato”) voice are classic presenting symptoms of peritonsillar cellulitis/abscess.

PHYSICAL EXAM

- Erythema, edema, tenderness, and warmth: usual clinical findings of cellulitis
- Distinct demarcation of raised erythema: classic description of erysipelas, a superficial cellulitis usually associated with *S. pyogenes*
- A red streak extending proximally from the extremity: lymphangitis, which usually implies more serious involvement
- Regional adenopathy: commonly associated with minor cellulitis; occasionally complicated by lymphadenitis

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- WBC: normal or elevated
- Blood culture: rarely positive. Ill-appearing children and children with extensive areas of cellulitis may warrant a blood culture.
- Wound culture: As resistance continues to rise (especially MRSA), wound cultures are useful.

Imaging

- Radiographs: sometimes helpful to rule out complications such as osteomyelitis. Also useful in cases of suspected foreign bodies
- Ultrasound: often useful to distinguish cellulitis from abscess, which might need incision and drainage (I&D).
- Head CT scan: important in cases when clinical distinction between periorbital and orbital cellulitis is difficult. Useful in orbital cellulitis to delineate extent of disease

Diagnostic Procedures/Other

In some cases, a cutaneous biopsy, examined by an experienced pathologist, may be needed to identify the correct diagnosis.

DIFFERENTIAL DIAGNOSIS

- Allergic angioedema can be excluded by its lack of tenderness and the absence of fever.
- Allergic reactions to insect stings are usually pruritic and may present with mild to severe local erythema, a bite history confirmatory.
- Red giant urticarial lesions, similarly, may masquerade as cellulitis.
- Contact dermatitis is distinguished by its painlessness, pruritus, and the Koebner phenomenon (appearance of isomorphic lesions in the lines of scratching).
- Nummular eczema is a pruritic dermatitis consisting of one or more circular lesions with papules, scales, and/or crusting, typically distributed on the trunk or extremities.
- The erythema migrans rash of Lyme disease starts as a red macule at the tick bite site, then expands to a large, annular, erythematous lesion; the classic “bulls eye” lesion with central clearing is not always seen.
- A traumatic contusion may be mistaken for cellulitis; the history confirms the diagnosis.
- Severe conjunctivitis presents with conjunctival injection, chemosis,

and discharge.

- “Popsicle panniculitis,” a cold-induced fat injury to the cheeks of infants; mimics buccal cellulitis; a history of cold weather exposure, eating ice, or popsicle sucking, are classic.
- Erythema nodosum, a panniculitis with raised, tender lesions that are frequently over the shins; may present as a single erythematous lesion. Associated with systemic disorders, including inflammatory bowel disease
- Superficial thrombophlebitis is distinguished by a tender cord palpable along the course of the affected superficial vein.
- An eye malignancy (retinoblastoma), invasive tumor (rhabdomyosarcoma), or metastatic disease (neuroblastoma, leukemia, lymphoma) may simulate periorbital or orbital cellulitis.

TREATMENT

MEDICATION

- Most cases of uncomplicated, superficial “nonpurulent” cellulitis (cellulitis with no purulent drainage or exudate, and no associated abscess) may be treated with β -lactam oral antibiotics active against β -hemolytic streptococci and MSSA (e.g., cephalexin or amoxicillin-clavulanate).
- Coverage for MRSA is indicated in patients who do not respond to initial therapy, patients with signs of systemic illness, patients with recurrent infection in the setting of underlying predisposing conditions, and patients with a previous episode of MRSA infection.
- Additionally, MRSA coverage should be considered in patients with MRSA risk factors, and in areas where the prevalence of MRSA is greater than 30%.
- Patients with purulent cellulitis (cellulitis associated with purulent drainage or exudate, in the absence of a drainable abscess) should be treated with antibiotics active against MRSA.
- Clindamycin is an excellent initial choice due to its activity against β -hemolytic streptococci and both MSSA and MRSA.
- Trimethoprim-sulfamethoxazole covers both MSSA and MRSA, but

not β -hemolytic streptococci; consequently, some combine it with amoxicillin.

- Some experts feel that initial coverage against β -hemolytic streptococci is not always mandatory in patients with purulent cellulitis; thus, monotherapy with trimethoprim-sulfamethoxazole is also sometimes used.
- Doxycycline and minocycline are additional alternatives with good MRSA coverage, especially for penicillin-allergic patients.
- Erythromycin is also sometimes used in patients allergic to penicillin; isolates resistant to erythromycin exist, however, and may be cross-resistant to clindamycin as well.
- Ill-appearing children or those with extensive cellulitic lesions require IV antibiotics.
- As MRSA infections continue to rise, most experts now recommend clindamycin as initial parenteral therapy.
- Oxacillin, nafcillin, cefazolin, and ampicillin-sulbactam are reasonable alternatives when MRSA is not strongly suspected.
- Vancomycin is used as empiric therapy in ill-appearing children or with severe or rapidly progressive infections.
- Linezolid, a newer antibiotic that can be given IV or PO, is very effective against MRSA, but it is expensive and should mostly be reserved for multiresistant organisms.
- If hematogenous dissemination is a strong possibility, an agent active against Hib also should be added (e.g., ceftriaxone, cefotaxime).
- The duration of antibiotics (IV and PO) should generally be 7–10 days.
- Bite wounds should have tetanus and rabies prophylaxis issues addressed.

ALERT

- Remember to consider the possibility of MRSA in all deep, invasive, or persistent infections (i.e., consider clindamycin).
- Penicillin and amoxicillin are never good empiric choices for cellulitis because they have poor *S. aureus* coverage.

ADDITIONAL TREATMENT

General Measures

Local care of cellulitis involves elevation and immobilization of the limb to reduce swelling, and cool sterile saline dressings to remove purulence from open lesions.

SURGERY/OTHER PROCEDURES

Abscesses should always be drained.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Steady improvement should be expected.
- If daily improvement is not noted, consider the following:
 - Inappropriate antimicrobial coverage
 - A deeper infection or abscess that needs drainage
 - Foreign body

PROGNOSIS

The prognosis for complete recovery is good as long as appropriate antimicrobials are administered in a timely fashion.

COMPLICATIONS

- Local or distant spread of infection is possible.
- Suppuration and abscess formation may occur (e.g., peritonsillar abscess).
- Extremity cellulitis may extend into the deep tissues to produce an arthritis or osteomyelitis, or it may extend proximally as a lymphangitis.
- Orbital cellulitis may be complicated by visual loss and/or cavernous sinus thrombosis.
- Prior to widespread immunization against Hib, the bacteremia associated with facial cellulitis was associated with pneumonia, meningitis, pericarditis, epiglottitis, arthritis, and osteomyelitis.

CODES

ICD10

- L03.90 Cellulitis, unspecified
- H05.019 Cellulitis of unspecified orbit
- J36 Peritonsillar abscess

FAQ

- Q: Is IV ampicillin-sulbactam adequate initial parenteral therapy for cellulitis with abscess?
- A: No. MRSA should be covered in these patients. IV clindamycin is a better choice.
- Q: When should IV vancomycin be used?
- A: IV vancomycin should be reserved for ill-appearing children or those with severe or rapidly progressive infections. These are cases where any treatment delay waiting for definitive culture and sensitivity results is prohibitive.

CEREBRAL PALSY

Stephen Contompasis

BASICS

DESCRIPTION

Cerebral palsy (CP) describes a group of disorders of movement and posture, limiting activity, attributed to nonprogressive underlying brain pathology. The motor disorders of CP are often accompanied by disturbances of sensation, cognition, communication, perception, and/or behavior or by a seizure disorder:

- Spastic (pyramidal; 75%): increased deep tendon reflexes, sustained clonus, hypertonia, and the clasp-knife response:
 - Spastic diplegia: lower extremity involvement
 - Spastic hemiplegia: 1 side of the body involved
 - Spastic quadriplegia: total body involvement; usually associated with dystonia
- Dyskinetic (10%): fluctuating tone, rigid total body involvement by definition. Persistent primitive reflex patterns (asymmetric tonic neck reflex, labyrinthine)
 - Athetoid: slow writhing movements (or chorea; rapid, random, jerky movements)
 - Dystonic: posturing of the head, trunk, and extremities
- Ataxic (<10%): characterized by cerebellar signs (ataxia, dysmetria, past pointing, tremor, nystagmus) and abnormalities of voluntary movement
- Mixed (10%): 2 or more types codominant, most often spastic and dyskinetic
- Other (10%): Criteria for CP met, but specific subtype cannot be defined.
- Extrapyramidal: sometimes applied to nonspastic types of CP as a group

EPIDEMIOLOGY

- ~50% of cases are associated with prematurity.

- Increased concordance among monozygotic versus dizygotic twins in some studies (not in others)
- Intrauterine growth retardation (IUGR) more common in CP than controls, especially for full-term infants in whom CP develops.
- Male > female (1.3:1)
- Inconsistent relationship to maternal age, socioeconomic status, and parity
- Prenatal factors are more strongly associated with subsequent CP than are perinatal or postnatal factors; however, individual risk factors are poorly predictive of subsequent CP in the individual child.
- Perinatal asphyxia accounts for only ~9% of CP; diagnosis requires evidence of hypoxic-ischemic insult, severe encephalopathy (e.g., neonatal seizures, severe hypotonia), and consistent laboratory/radiologic findings.
- Increased with multiple gestation (10% were twins in 1 study)
- Prevalence ~2–3/1,000

ETIOLOGY

- Not apparent in most cases. A more recently recognized perinatal factor is the presence of chorioamnionitis; mild or even subclinical infection may have increased association with CP.
- Epidemiologic studies indicate 2 types of associated vulnerability to CP:
 - Prematurity: Vulnerability of the periventricular white matter between 28 and 32 weeks of gestation results in periventricular leukomalacia.
 - IUGR: Fetal growth retardation associated with CNS dysgenesis, non-CNS malformation, teratogens, growth retardation, evidence of hypoxic-ischemic encephalopathy.

COMMONLY ASSOCIATED CONDITIONS

- Sensory
 - Sensorineural and conductive hearing loss
 - Impaired visual acuity
 - Oculomotor dysfunction
 - Strabismus

- Cortical visual impairment
- Somatosensory impairments
- Cognitive/developmental
 - Intellectual disability in ~50%, especially in spastic quadriplegia
 - Autism, ADHD
 - Language and learning disabilities
 - Dysarthria
 - Sleep and behavioral disturbances
- Neurologic
 - Seizures
 - Hydrocephalus
- Musculoskeletal
 - Contractures
 - Hip subluxation/dislocation
 - Scoliosis
- Cardiorespiratory
 - Upper airway obstruction
 - Aspiration pneumonitis
 - Restrictive lung disease/thoracic deformity
 - Reactive airway disease
- GI/nutritional
 - Poor growth
 - Gastroesophageal reflux
 - Constipation
 - Oral motor dysfunction/dysphagia
- Urinary: neurogenic bladder
- Skin: decubitus ulcers
- Dental
 - Malocclusions
 - Caries
 - Gingival hyperplasia
 - Abnormalities of enamel (congenital)

DIAGNOSIS

HISTORY

- Prenatal
 - Exposure to toxins/drugs
 - Infections or fever
 - HIV/STD risk
 - Vaginal bleeding
 - Abnormal fetal movement
 - Preeclampsia (especially proteinuria)
 - Breech position
 - Poor maternal weight gain
 - Premature labor
 - Fetal distress
 - IUGR
 - Prenatal testing
 - Placental disorders
- Perinatal
 - Premature delivery
 - Neonatal resuscitation
 - Low Apgar scores (<5 at 5 minutes)
 - Birth trauma
 - Evidence of neonatal encephalopathy (seizures, lethargy, hypotonia)
 - Complicated neonatal course (intraventricular hemorrhage, prolonged respiratory support, meningitis, sepsis, hyperbilirubinemia)
- Postnatal
 - Hospitalization for severe infection or trauma
 - Periodic or persistent deterioration in function (suggests neurodegenerative/metabolic disease)
- Development
 - Significant delay in motor milestones/motor quotient (age of typical skill attainment/age of attainment <0.5) (e.g., not rolling at 10 months, not sitting at 12 months, not walking at 24 months)
 - Associated with persistent primitive reflexes (e.g., prominent tonic neck and labyrinthine responses at 1 year of age) and delayed or absent development of protective reactions (e.g., lateral prop at 7

- months, parachute at 13 months)
- Associated delays in language, play, social, and adaptive behavior

PHYSICAL EXAM

- General observation: evidence of dysmorphism/pigmentary skin changes and growth abnormalities
- Head circumference: to evaluate for microcephaly/macrocephaly/hydrocephaly; growth velocity points to timing of brain pathology
- Strabismus/cataracts/iris or retinal abnormalities: eye exam: cranial nerve damage, muscle imbalance, metabolic disease, or congenital infection
- Musculoskeletal
 - Decreased range with contractures
 - Leg length discrepancy: hip dislocation
 - Spinal curvature/scoliosis
- Neurologic
 - Documentation of best level of visual motor/manipulative skills (transfer, hold a cup): to follow course of motor impairment
 - Cranial nerves: strabismus, speech and swallowing, vision and hearing
 - Tone: spasticity versus rigidity versus hypotonia
 - Strength: often decreased
 - Hyperactive deep tendon reflexes and clonus in spasticity; Babinski reflex (extensor response to plantar stimulation)
 - Persistent primitive reflexes
 - Protective reactions: head and trunk righting, prop reactions, parachute; cerebellar signs
 - Balance, stability

ALERT

Pitfalls

- Overdiagnosis of CP in premature infants with spastic hypertonia; normalization of tone/function may take up to 2 years.
- False or premature assumption of cognitive deficit in children with severe dysarthria. May take years of augmentative communication

supports to determine true potential

- Slowly progressive neurodegenerative diseases and pediatric neurotransmitter disorders may masquerade as CP.
- Cervical cord lesions may masquerade as quadriparetic spastic CP.
- Determination of ideal body weight/caloric requirements may be complex in CP; skinfold measuring <10th percentile is the best indicator of poor nutrition.
- Pain is a common problem, with more than half of adults and children with CP reporting pain as an ongoing health concern.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Genetic and metabolic studies: if history or physical suggests a progressive or hereditary disorder
- Blood chemistries, liver function studies, cell counts: evaluate nutritional/metabolic status, anticonvulsant levels

Imaging

- Brain imaging: perform when hydrocephalus is suspected; can help determine etiology
- Radiography: should be done routinely in spastic diparesis for hip dislocation; consider scoliosis films.
- Radionuclide studies to evaluate gastroesophageal reflux, gastric emptying, aspiration

Diagnostic Procedures/Other

- Hearing and vision: all in 1st year, with regular follow-up exams
- Audiologic evaluation required per guidelines
- Urodynamic studies: spastic bladder in those with recurrent UTIs or voiding dysfunction
- Sleep study: may disclose treatable obstructive sleep apnea in those with somnolence or abnormal sleep–wake cycles
- Pulmonary function studies: document progressive restrictive pulmonary dysfunction (e.g., in severe scoliosis)
- Consider bone density: liability to fracture
- Brain wave (EEG): if seizure suspected

DIFFERENTIAL DIAGNOSIS

- Motor syndromes related to spinal cord, lower motor neuron, peripheral nerve, primary muscular disease, or progressive disorders of the basal ganglia (dopa-responsive dystonia)
- Connective tissue disorders (primary and secondary) resulting in musculoskeletal abnormalities (e.g., arthrogryposis multiplex, skeletal dysplasias)
- Inborn errors of metabolism and CP: protean manifestations, dyskinesia, ataxia, postnatal growth failure, neurologic deterioration, recurrent vomiting

TREATMENT

ADDITIONAL TREATMENT

General Measures

- Family-centered care is directed toward optimizing activity and participation.
- Interdisciplinary clinics: services (medical, surgical, therapy) coordinated with primary physician
- More frequent health maintenance visits and coordination meetings from a medical home practice may assist in managing multiple chronic associated health conditions.
- Spasticity reduction with IM injections of botulinum toxin is well supported. Oral or intrathecal baclofen used increasingly, although consensus on functional improvement long term is variable.
- Orthopedic management with directed procedures to reduce contractures and improve posture has more evidence on improving functional outcomes long term.
- Education services: recent emphasis on inclusion/mainstreaming; for many, special education services are still required.
- Augmentative communication supports especially for nonverbal/dysarthric children.
- Physical, occupational, speech/language therapy, other allied health professionals: Therapy provided in home, school, and hospital settings; directed primarily at improved mobility, self-care, and communication;

orthodontists for braces

- Counseling support for children coping with chronic disability
- Social services: provided in a variety of contexts to aid in the coordination of care
- Vocational counseling and employment options, assistance with transition to adulthood, self-advocacy, self-determination
- Transition to adult health care system

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Requirements for follow-up vary greatly with the degree of disability and impairment. An interdisciplinary clinic setting may be more appropriate for a child with severe CP.
- Early referral to a pediatric orthopedist is indicated, especially for monitoring of the hip.
- Early referral for developmental assessment: need for early intervention to optimize development and promote family coping

DIET

Nutritional assessment and support for those with dysphagia or poor growth (especially calcium, vitamin D intake)

CODES

ICD10

- G80.9 Cerebral palsy, unspecified
- G80.1 Spastic diplegic cerebral palsy
- G80.2 Spastic hemiplegic cerebral palsy

FAQ

- Q: Is severe clumsiness a form of CP?
- A: Mild spastic diplegia or hemiplegia may present this way, but tone abnormalities and significant functional impairments distinguish CP from milder developmental coordination disorders.
- Q: Do all children with CP also have intellectual disability?
- A: Only ~50% have intellectual disability.

CERVICITIS

Elizabeth M. Wallis • Sarah E. Winters

BASICS

DESCRIPTION

Infection of the endocervix resulting in inflammation, leading to mucopurulent cervical discharge, edema, erythema, bleeding, and friability of the cervix and endocervical canal

EPIDEMIOLOGY

- The true incidence of cervicitis is unknown; however, the primary causes (gonorrhea/chlamydia) are more common in adolescents and young adults than any other age group.
- Because many patients are asymptomatic and the interpretation and presence of the clinical signs is quite variable, many cases go undiagnosed.

RISK FACTORS

- Early age of coitarche
- Multiple sexual partners
- Absent or inconsistent condom use

ETIOLOGY

In most cases of cervicitis, no pathogen is isolated. Common causes include the following:

- Chlamydia trachomatis
- Neisseria gonorrhoeae
- Herpesvirus hominis
- Trichomonas vaginalis
- Mycoplasma genitalium

COMMONLY ASSOCIATED CONDITIONS

The presence of other sexually transmitted infections (STIs) must be considered, including the following:

- Syphilis

- Hepatitis B
- HIV
- Bacterial vaginosis

DIAGNOSIS

HISTORY

- Often asymptomatic
- If symptomatic: Symptoms consistent with but not diagnostic of cervicitis:
 - Abnormal vaginal bleeding and/or discharge? Inflamed cervix may bleed spontaneously or following sexual intercourse.
 - Dysuria? May indicate urethritis or bladder infection
 - Vulvar itching? May be associated discharge from cervical inflammation or a coexisting vaginal infection
 - Dyspareunia? Common complaint owing to the sensitive cervix
- Past medical history—important to evaluate risk factors related to sexual health but not diagnostic of cervicitis
 - Previous STI? Identifies patients at increased risk for reinfection
 - Last menstrual period? Symptomatic infection often occurs within 7 days of the last menstrual period because of loss of the protective endocervical mucous plug.
 - Birth control method? Condoms are protective.
 - Exposure to infected partner? Identifies patient at increased risk
 - Gravity?
 - Parity?

PHYSICAL EXAM

- Abdominal exam
 - No tenderness on palpation of the abdomen suggests that infection is limited to the cervix.
- Vaginal exam
 - Assess for signs of vaginal/external lesions consistent with herpes simplex virus (HSV).
- Pelvic exam

- Mucopurulent discharge from the cervical os or yellow exudative discharge present on a cotton-tipped swab from the endocervical canal: clinical evidence of cervical infection
- No cervical motion or adnexal tenderness or masses: Pathology has not extended beyond the cervix to the upper genital tract.
- Friability of the exocervix: easily induced bleeding from the cervical canal not to be confused with normal cervical ectopy (area of columnar epithelium around the cervical os presenting as a discrete, nonfriable, reddish circle)

ALERT

Pitfalls:

- Failure to recognize the importance of evaluating the internal pelvic organs by physical examination with the presenting symptoms of dysuria, vaginal discharge, or abnormal menstrual bleeding in the postpubertal female
- Imperative not to confuse normal cervical ectropion in an adolescent with cervicitis

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Nucleic acid amplification tests done on the patient's urine offers the least invasive method to detect Chlamydia, gonococcal, and Trichomonas infections. Cervical or vaginal swabs may also be used for nucleic acid amplification tests, provided that there is no bleeding:
 - Cervical swabs, vaginal swabs obtained by the health care provider, and urine have similar sensitivity and specificity.
 - Cervical cultures for chlamydia and gonorrhea will also identify the pathogen but require a speculum examination.
 - Identifies the pathogen, which is important for patient and partner treatment and disease surveillance
- HSV culture if vesicular rash or ulcers are present: important to identify the cause of the ulcers for treatment and patient counseling
- Wet preparation and vaginal pH may be helpful in diagnosing bacterial vaginosis.

DIFFERENTIAL DIAGNOSIS

- It is helpful to consider cervicitis/vaginitis as a single disease in the evaluation process because the symptoms of these 2 entities are the same.
- Inflammation of the vulva, urethra, and/or bladder, and vagina
- In patients presenting with abnormal menstrual bleeding, these infectious causes are common.
- Pregnancy is a frequent cause of abnormal vaginal bleeding.
- Foreign body can be associated with both discharge and bleeding.
- Polycystic ovary syndrome (PCOS), thyroid dysfunction, and hyperprolactinemia can all present with abnormal vaginal bleeding.
- Noninfectious cervicitis occurs and is primarily caused by mechanical or chemical irritation (foreign objects, latex, vaginal douches, contraceptive creams).

TREATMENT

MEDICATION

- Gonorrhea
 - Ceftriaxone 250 mg IM or, PLUS azithromycin 1 g PO, single dose or doxycycline 100 mg PO b.i.d. for 7 days. Oral cefixime is no longer recommended as first line due to resistance. If cefixime is used because ceftriaxone is not available, a test of cure is necessary.
 - Recently, noticed patterns of resistance to fluoroquinolones have caused the CDC to no longer recommend this class as first line of treatment of gonococcal cervicitis in the United States.
 - If fluoroquinolones are used, a test of cure is necessary.
- C. trachomatis
 - Azithromycin 1 g PO, single dose
 - Doxycycline 100 mg PO b.i.d. for 7 days
 - Erythromycin base 500 mg PO q.i.d. for 7 days
- T. vaginalis
 - Metronidazole 2 g PO, single dose
 - Metronidazole 500 mg PO b.i.d. for 7 days
 - Tinidazole 2 g PO in a single dose
- H. hominis

- Acyclovir 400 mg PO t.i.d. for 7–10 days or until resolution
- Acyclovir 200 mg PO 5 times daily for 7–10 days or until resolution
- Famciclovir 250 mg PO t.i.d. for 7–10 days or until resolution
- Valacyclovir 1 g PO b.i.d. for 7–10 days or until resolution

INPATIENT CONSIDERATIONS

Initial Stabilization

Patients meeting the criteria for the clinical diagnosis of cervicitis or those who have a high likelihood of infection should receive presumptive therapy for *N. gonorrhoeae* and *C. trachomatis*. Treat other pathogens if clinically indicated or if documented by laboratory studies.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- The recommended treatment regimens have an excellent cure rate.
- The patient should have resolution of symptoms 3–5 days after starting therapy.
- Patients should abstain from intercourse until 7 days after both partners have been treated to prevent reinfection.
- Routine follow-up cultures are not necessary unless the patient remains symptomatic or in the case of pregnancy.
- Nucleic acid amplification tests done <6 weeks following treatment may yield false-positive results because of persistence of dead organisms.
- Detection of an STI at follow-up is most likely the result of reexposure and reinfection.

Patient Monitoring

- Partners should be referred for evaluation and treatment if laboratory diagnosis of gonorrhea/chlamydia or *Trichomonas* is made.
- Gonorrhea/chlamydia are reportable STIs.

PROGNOSIS

If treated appropriately, patients are cured and have no sequelae from the infection.

COMPLICATIONS

The patient with endocervical infection is at risk for the following:

- Reinfection
- Other STIs
- Pregnancy
- Symptomatic or asymptomatic upper genital tract disease (pelvic inflammatory disease), with all its sequelae:
 - Tubo-ovarian abscess
 - Infertility
 - Ectopic pregnancy
 - Chronic pelvic pain

CODES

ICD10

- N72 Inflammatory disease of cervix uteri
- A54.03 Gonococcal cervicitis, unspecified

- A56.09 Other chlamydial infection of lower genitourinary tract

FAQ

- Q: How much cervical motion tenderness is present in patients with cervicitis?
- A: None. Patients with cervicitis have inflammation and infection of the cervix only. They do not have any evidence of peritoneal inflammation on physical examination; therefore, patients with tenderness should be treated with the protocols recommended by the CDC for pelvic inflammatory disease. This does not include the use of a single dose of azithromycin.
- Q: Which partners should be referred for treatment?
- A: Sex partners from the preceding 60 days should be referred for evaluation and treatment. Treatment is based on documented or presumptive etiologies.
- Q: What is the appropriate treatment for M. genitalium?
- A: M. genitalium has clearly been implicated in the development of urethritis in males and is thought to play some role in the development of cervicitis in females (although that role is not entirely clear). Data suggests that azithromycin may be the best treatment for this infection.
- Q: How often should asymptomatic sexually active adolescents be screened for STIs?
- A: Sexually active men and women younger than 25 years of age should be screened annually for STIs.

CHANCROID

Evelyn Porter • Christine S. Cho

BASICS

DESCRIPTION

Sexually transmitted infection caused by *Haemophilus ducreyi* that manifests as painful genital skin ulcerations and inguinal lymphadenopathy

EPIDEMIOLOGY

- Low incidence in the United States with sporadic outbreaks
- In underdeveloped countries, a major cause of genital ulcer syndrome
- Probably underreported due to difficulty with definitive diagnosis via culture in developing areas
- Increases the risk of HIV transmission
- Seen more commonly in males; females are more likely to be asymptomatic.
- Sexual contact is the only known route of transmission.
- If diagnosed in children, sexual abuse should be considered.

Incidence

Cases in the United States steadily declined until 2000; since then, the incidence has fluctuated. In 2012, there were 15 reported cases.

RISK FACTORS

Increased association with sex workers and individuals involved in drug use

GENERAL PREVENTION

Condom use

PATHOPHYSIOLOGY

- Transmission suspected via microabrasions sustained during sexual intercourse, allowing the organism to penetrate the epidermis
- 3–10 days later, an erythematous, tender papule develops and progresses to a pustule.

- The pustule ruptures after 2–3 days, leaving a shallow ulcer with a painful, necrotic base with undermined edges.
- Single or multiple ulcers may be present.

ETIOLOGY

H. ducreyi, a gram-negative coccobacillus

COMMONLY ASSOCIATED CONDITIONS

- Associated with HIV transmission and infection
- Coinfection with syphilis and human herpes virus may occur (10%).

DIAGNOSIS

Diagnosis of chancroid is routinely based on clinical findings after the exclusion of other causes of genital ulcer disease.

HISTORY

- Males usually present with symptoms referable to an acute, painful genital ulcer.
- Females may be asymptomatic or present with nonspecific symptoms (dysuria, vaginal discharge, pain with stooling or sexual intercourse, rectal pain, or bleeding).

PHYSICAL EXAM

Classic findings:

- Extremely painful ulcer with an irregular, undermined border and a gray, necrotic center
 - In males: found on prepuce or coronal sulcus
 - In females: found on the vulva, cervix, or perianal area
- Painful, unilateral, inguinal lymphadenopathy (bubo) in 50% which may spontaneously drain
- Extragenital sites are rare and include the inner thigh area, breasts, fingers, and mouth.

DIAGNOSTIC TESTS & INTERPRETATION

Diagnosis is made by clinical findings and exclusion of other causes of genital ulcers.

Lab

- Gram stain from the base of the ulcer: may show short gram-negative coccobacilli in parallel “school of fish” arrangement. Not reliable as a screening test as ulcers may contain multiple organisms; routine use is not helpful.
- Cultures from the ulcer
 - *H. ducreyi* is a fastidious organism and requires specialized media and technique for successful isolation.
 - Compared with newer amplification techniques, it has been proven to be 75% sensitive.
 - Currently the only method routinely available for the definite diagnosis of chancroid
- DNA amplification
 - A genital ulcer multiplex polymerase chain reaction (GUM) test has been developed for simultaneous amplification of DNA targets from *H. ducreyi*, *Treponema pallidum*, and herpes simplex virus (HSV) types 1 and 2; offers improved sensitivity when compared with culture
 - This technology is not routinely available.
- Monoclonal antibody
 - Monoclonal antibody against the outer membrane protein of *H. ducreyi* using immunofluorescent antibody has also proven to be more sensitive than culture.
 - Could provide easy, rapid, inexpensive, sensitive testing but not available currently
- Additional testing
 - Evaluation for the common causes of genital ulcer syndrome should be done routinely: culture and PCR for HSV 1 and 2, RPR
 - HIV test

DIFFERENTIAL DIAGNOSIS

- Chancroid must be distinguished from the other causes of genital ulcers, including syphilis, HSV, lymphogranuloma venereum, and granuloma inguinale. More than one of these pathogens may be present in individual cases.
- Uncommon etiologies include the following:

- Trauma
- Fixed drug eruptions
- Inflammatory bowel disease
- Behçet syndrome

TREATMENT

MEDICATION

- Azithromycin 20 mg/kg (max 1 g) PO, once
- Ceftriaxone 50 mg/kg (max 250 mg) IM, once
- Ciprofloxacin 500 mg b.i.d. for 3 days (patients >18 years)
- Erythromycin base (≥ 18 years) 500 mg PO q.i.d. for 7 days
- One-time directly observed dosing with azithromycin or ceftriaxone is recommended.

SURGERY/OTHER PROCEDURES

Persistent inguinal fluctuant adenitis may be treated with either needle aspiration or incision and drainage.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Symptoms improve within 3–7 days.
- Ulcers heal between 1 and 4 weeks.
- Lymphadenopathy may take longer to regress; may become fluctuant despite adequate therapy
- Patients should be followed weekly until symptoms resolve.
- For patients who do not follow the typical course, consider other causes of genital ulcers; noncompliance; presence of a coexisting sexually transmitted disease, especially HIV; and, rarely, presence of a resistant organism.
- Recent sexual partners (within the preceding 10 days) should be treated.
- If initial HIV and syphilis test results are negative, they should be repeated in 3 months following diagnosis of chancroid.

PATIENT EDUCATION

Prevention: condom use with all sexual activity

COMPLICATIONS

- Draining bubo
- Coinfection with syphilis and HSV
- HIV infection

CHEST PAIN

Steven M. Selbst

BASICS

DESCRIPTION

Chest pain is a common pain syndrome in childhood. It is less common than abdominal pain and headache. Cardiac disease is an uncommon etiology. Musculoskeletal cause is most common. Boys and girls are equally affected. Etiology is often unclear (idiopathic).

COMMONLY ASSOCIATED CONDITIONS

- Asthma
- Cystic fibrosis
- Diabetes mellitus (long-standing)
- Hypertrophic cardiomyopathy
- Kawasaki disease
- Marfan syndrome
- Sickle cell disease
- Systemic lupus erythematosus

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- **Musculoskeletal disorders**
 - Chest wall strain
 - Costochondritis
 - Direct chest trauma
 - Slipping rib syndrome
- **Cardiac pathology**
 - Arrhythmia (supraventricular tachycardia, premature ventricular contractions)
 - Coronary artery anomalies
 - Coronary artery aneurysms (Kawasaki disease)

- Infections (myocarditis, pericarditis)
- Myocardial infarction/ischemia
- Structural abnormalities: hypertrophic cardiomyopathy
- **GI disorders**
 - Caustic ingestions
 - Esophageal foreign bodies
 - Esophagitis (sometimes tetracycline or “pill” induced)
- **Psychogenic causes**
 - Anxiety/stress
 - Hyperventilation
- **Respiratory disorders**
 - Asthma
 - Cough (prolonged)
 - Pleural effusion
 - Pneumonia
 - Pneumothorax: spontaneous, trauma related, drug related (cocaine)
 - Pneumomediastinum
 - Pulmonary embolism
- **Miscellaneous**
 - Breast mass
 - Cigarette smoke
 - Pleurodynia
 - Precordial catch syndrome
 - Shingles
 - Sick cell crises—acute chest syndrome
 - Thoracic tumor

APPROACH TO PATIENT

Identify the rare child with a serious cause for chest pain (see discussion in “[Physical Exam](#)”—[Important Physical Findings on General Examination of Child with Chest Pain])

- **Phase 1:** Is the patient in acute distress? If so, begin emergency management and proceed rapidly to find the cause of pain.
- **Phase 2:** For most stable children with chest pain, determine whether laboratory tests are needed to help identify the cause.
- **Phase 3:** Treat specific conditions as appropriate. Begin analgesics,

reassure the family, and arrange for follow-up care.

Hints for Screening Problems

Take a thorough history and perform a careful physical exam. Examine the chest last—do not focus only on this area. Use laboratory tests sparingly, only to confirm clinical suspicions.

HISTORY

- **Question:** How severe, how often is the pain?
- **Significance:** Constant, frequent severe pain is more likely to be distressing and interruptive of daily activity. Serious etiology is not well correlated with frequency and severity of pain.
- **Question:** What is the type of pain? Where is its location?
- **Significance:** Burning pain is associated with esophagitis. Sharp, stabbing pain relieved by sitting up or leaning forward is typical of pericarditis. Young children do not describe or localize chest pain well.
- **Question:** When was the onset of pain?
- **Significance:** Acute pain (<48 hours) is more likely to have an organic cause. Chronic pain (>6 months) is more likely to be psychogenic or idiopathic. In an older child with sudden onset of pain, consider an arrhythmia, pneumothorax, or musculoskeletal injury. In a young child with sudden onset of pain, consider a foreign body (coin) in the esophagus or injury.
- **Question:** Is the pain induced by exercise?
- **Significance:** Exercise-induced chest pain may be related to serious cardiac disease or asthma.
- **Question:** Recent trauma, rough play, or muscle overuse?
- **Significance:** Musculoskeletal (chest wall) pain
- **Question:** Eaten spicy foods? Taken tetracycline or other pills?
- **Significance:** Esophagitis. Teens often take pills with little water and then lie down. The undissolved pill may lodge in the esophagus and cause pain.
- **Question:** Recent use of “street drugs” such as cocaine?
- **Significance:** Hypertension, tachycardia, myocardial ischemia, or pneumothorax
- **Question:** Use of oral contraceptives, clotting disorder, or recent leg

trauma?

- Significance: Pulmonary embolism. This is rare in the pediatric age group.
- **Question:** Recent significant stress (e.g., move, death of loved one, serious illness)?
- Significance: Psychogenic pain. Children may have headaches and abdominal pain related to stress. Chest pain may also relate to unusual stress.
- **Question:** Associated complaints?
- Significance: Fever may imply pneumonia (common), myocarditis, and pericarditis (less common but serious). Syncope and palpitations may imply cardiac arrhythmias or severe anemia. Joint pain or rash may relate chest pain to collagen vascular disease. Pain that resolves with parental attention may indicate an emotional cause.
- **Question:** Positive familial history?
- Significance: Hypertrophic cardiomyopathy is often familial. Those with this disorder may have familial history positive for sudden death. When there is a positive familial history of heart disease or chest pain, the parents may be unusually concerned about the symptom in a child. The child often has a nonorganic cause.
- **Question:** Past medical history?
- Significance: Previous Kawasaki disease, long-standing insulin-dependent diabetes mellitus, and sickle cell disease may have serious cardiac or pulmonary complications leading to chest pain. Marfan syndrome has increased risk for aortic dissection and pneumothorax. Asthma has increased risk for pneumonia and pneumothorax. Collagen vascular disease has increased risk for pleural effusion and pericarditis. Most underlying structural cardiac lesions rarely produce chest pain. Hypertrophic cardiomyopathy is a high-risk situation.

PHYSICAL EXAM

- **Important physical findings on general examination of child with chest pain**
 - Severe distress
 - Chronically ill appearance
 - Fever

- Skin rash or bruising
- Abdominal pathology
- Arthritis present
- Anxiety apparent
- **Finding:** Child is in significant distress?
- Significance: Requires emergency care; stabilization. Consider pneumothorax or arrhythmia.
- **Finding:** Child appears chronically ill?
- Significance: Chest pain may be found in serious illnesses such as malignancy (Hodgkin lymphoma) or systemic lupus erythematosus.
- **Finding:** Fever?
- Significance: Consider pneumonia, myocarditis, or pericarditis.
- **Finding:** Skin bruising present?
- Significance: Chest pain may be related to unrecognized trauma. Osteomyelitis of the rib is a rare cause.
- **Finding:** Abdominal pathology?
- Significance: Pain may be referred to the chest.
- **Finding:** Arthritis present?
- Significance: Collagen vascular disease may manifest as pleural effusion or chest pain.
- **Finding:** Unusually anxious child?
- Significance: Underlying stress may lead to pain.
- **Important physical findings on chest examination of child with chest pain**
 - Breast abnormality
 - Subcutaneous emphysema
 - Heart murmur, rub, arrhythmia
 - Chest wall tenderness
- **Finding:** Breast enlargement, asymmetry, tenderness?
- Significance: Physiologic breast changes in young teens may be painful. Consider pregnancy in teenage girls.
- **Finding:** Decreased breath sounds, wheezing?
- Significance: May suggest pneumonia, asthma with overuse of chest wall muscles
- **Finding:** Subcutaneous emphysema palpable on chest or neck?

- Significance: Pneumothorax, pneumomediastinum
- **Finding:** Heart murmur, rub, arrhythmia?
- Significance: Congenital heart disease, hypertrophic cardiomyopathy, cardiac infections such as myocarditis, pericarditis, supraventricular tachycardia, ventricular tachycardia
- **Finding:** Tenderness of chest wall, costochondral junctions?
- Significance: Musculoskeletal pain

ALERT

Factors that make this an emergency include the following:

- Pneumothorax: may present with severe sudden chest pain, respiratory distress, cyanosis, hypotension
- Cardiac arrhythmia: Ventricular tachycardia or supraventricular tachycardia in an older child may progress to heart failure or a lethal rhythm.
- Cocaine intoxication: may present with pneumothorax, cardiac arrhythmia, hypertension
- Direct chest trauma: may lead to cardiac contusion and arrhythmia
- Caustic ingestions or esophageal foreign bodies require prompt attention.

DIAGNOSTIC TESTS & INTERPRETATION

- **Test:** EKG
- Significance
 - Obtain if history suggests cardiac pathology (e.g., acute onset of pain, pain on exertion, pain associated with syncope, dizziness, palpitations, history of congenital heart disease, serious associated medical problems [Kawasaki disease, diabetes mellitus], use of cocaine)
 - Obtain also if physical exam is abnormal. For instance, respiratory distress, cardiac abnormality, fever, significant trauma
- **Test:** Holter monitor
- Significance: Arrange for this study if cardiac arrhythmia is suspected. EKG may fail to detect intermittent arrhythmia.
- **Test:** Exercise stress test
- Significance: Obtain if pain is induced by exertion. Usefulness is

debated but may identify cardiac disease or asthma.

- **Test:** Drug screen
- Significance: Obtain if cocaine use is suspected.

Imaging

Chest radiograph

- Same as for EKG
- Obtain also if history suggests cardiac or pulmonary pathology, tumor, Marfan syndrome, or foreign body (coin ingestion).
- Obtain also if physical exam suggests decreased breath sounds or palpation of subcutaneous air.

TREATMENT

ADDITIONAL TREATMENT

General Measures

Chest pain in children is rarely related to cardiac pathology. However, not all children with chest pain have a benign etiology; pain associated with exertion, syncope, dizziness is concerning for heart disease; if the child is febrile, consider pneumonia or viral myocarditis. Treat specific cause when found. OTC analgesics (acetaminophen 15 mg/kg/dose, ibuprofen 10 mg/kg/dose) suffice for most pain. Antacids may be diagnostic and therapeutic for esophagitis pain. Rest, heat, and relaxation techniques may be useful. Avoid expensive, invasive laboratory studies with chronic pain and normal physical exam or benign history.

ISSUES FOR REFERRAL

- Acute distress
- Significant trauma
- History of heart disease or related serious medical problem
- Pain with exercise, syncope, palpitations, dizziness
- Serious emotional disturbance
- Esophageal foreign body, caustic ingestion
- Pneumothorax, pleural effusion
- Abnormal heart (or sometimes lung) exam
- Abnormal EKG

ONGOING CARE

PROGNOSIS

40% will have continued chest pain for 6–24 months. Follow-up care is important. Serious pathology is unlikely to be found if not diagnosed initially. However, watch for signs of exercise-induced asthma or for emotional problems that were not obvious initially. Encourage return to normal activity if evaluation is negative. Most have an excellent prognosis.

FAQ

- Q: How common is chest pain in children?

- A: Chest pain is a common pain syndrome reported in 6/1,000 children who present to an urban emergency department. The complaint is less common than abdominal pain or headache. Although children of all ages may complain of chest pain, the mean age is about 12 years.
- Q: Which features in the history are worrisome?
- A: Acute onset of pain, it occurs with exercise, associated syncope, dizziness or palpitations, heart disease or chronic conditions that can affect the heart, trauma, fever, drug use (e.g., cocaine)
- Q: Which findings on physical exam are most worrisome?
- A: Respiratory distress, decreased/abnormal breath sounds, cardiac abnormality, fever, trauma, subcutaneous air, Marfan features
- Q: Which children with chest pain do not need extensive evaluation with laboratory studies?
- A: Those with chronic pain (>6 months), and none of the worrisome features mentioned earlier. Individualized management—analgesics, reassurance, and follow-up usually suffice.
- Q: Why should clinicians be concerned about chest pain in children?
- A: Heart disease is an uncommon cause, but serious pathology is found in some cases. Parental fears must be addressed.

CHICKENPOX (VARICELLA, HERPES ZOSTER)

Camille Sabella

BASICS

DESCRIPTION

Varicella-zoster virus (VZV) is a highly contagious herpesvirus. Primary infection with the virus results in varicella (chickenpox), whereas reactivation from latency results in herpes zoster (shingles).

EPIDEMIOLOGY

- Transmission occurs by droplet and airborne transmission of infectious respiratory secretions or direct contact with vesicles and respiratory secretions.
- Incubation 10–21 days (usually 14–16 days) after exposure; cases most contagious 2 days before the rash appears until skin lesions have fully crusted.
 - Immunocompromised patients may have longer or shorter incubation.
 - Post–intravenous immunoglobulin (IVIG), incubation may be up to 28 days.
- The incidence of chickenpox has declined by 90% since the introduction of universal varicella vaccination.
- The attack rate for susceptible household contacts exposed to varicella is 90%.
- Disease is more severe in immunocompromised persons, infants >3 months of age, adolescents, adults, persons with pulmonary disorders (asthma), persons with chronic skin disorders (eczema), and persons on oral and/or intravenous (IV) steroids or long-term aspirin therapy.
- Congenital varicella embryopathy: Risk is 1–2% when maternal primary VZV infection occurs before the 20th week of gestation.
- The rate of complications from varicella has declined dramatically since the licensure of the varicella vaccine.

GENERAL PREVENTION

- Varicella vaccine
 - Live attenuated vaccine (Oka strain)
 - 2-dose series for routine immunization of all healthy, susceptible children; adolescents; and adults
- Immunogenicity: ~85% of immunized children developed protective levels of humoral and cellular immunity after 1 dose, ~100% with 2 doses; 3× less likely to have breakthrough disease when 2 doses of vaccine were administered
- Effectiveness: 70–90% effective against all VZV disease; >97% effective against severe disease (e.g., median number of vesicles was 50 in vaccinated children vs. 250 in unvaccinated children)
- Herpes zoster can occur following varicella vaccination, but clinical severity of the zoster is milder and the risk of acquiring zoster following immunization is lower than following wild-type chickenpox.
- Contraindications
 - Anaphylaxis to vaccine components (e.g., neomycin, gelatin)
 - Pregnant, immunocompromised, or <12 months of age
 - HIV is an exception: It is recommended to vaccinate HIV-positive children if CD4+ T-cell counts are $\geq 15\%$. Give doses 3 months apart.
 - High-dose corticosteroid doses of >2 mg/kg/day or >20 mg/day of prednisone, or its equivalent, for ≥ 14 days are considered immunosuppressive doses: VZV vaccine should not be given until systemic corticosteroid therapy has been discontinued for at least 1 month.
- Postexposure prophylaxis
 - If no contraindication to VZV vaccine: Administer VZV vaccine to susceptible hosts (1st or 2nd dose) within 72 hours (up to 120 hours) of exposure.
 - If with contraindications to VZV vaccine: Consider passive immunization.
- Passive immunization if
 - (i) No evidence of immunity in exposed person, (ii) probability that exposure will result in infection, and (iii) likelihood of

complications of VZV in the exposed person due to risk factors

- Susceptible immunocompromised people, pregnant women, and neonates whose mothers develop varicella infection 5 days prior to 2 days after delivery should be especially considered for passive immunization upon exposure.
- Administer varicella immunoglobulin (VariZIG) or IVIG as per protocol within 96 hours of exposure.
- If VariZIG or IVIG is unavailable, or >96 hours have passed, some experts recommend postexposure prophylaxis with oral acyclovir (20 mg/kg q6h for 7 days) beginning 7–10 days after exposure.

PATHOPHYSIOLOGY

- After primary infection, the virus establishes latency in dorsal root ganglia cells.
- Immunity from natural disease is usually lifelong, but symptomatic and asymptomatic reinfections do occur, boosting antibody levels.

DIAGNOSIS

HISTORY

- Chickenpox
 - Fever, malaise; decreased appetite common prior to onset of rash
 - Fever low grade to moderate and persists after rash appears
 - Pruritic rash begins on scalp, face, or trunk.
 - New lesions appear as some begin to crust; all stages (macules, vesicles, crusted lesions) apparent at one time.
 - Vesicles may appear in the mouth, conjunctiva, vagina, and urethra.
- Zoster
 - Prodrome of pain, pruritus, hyperesthesias
 - Vesicular lesions are clustered unilaterally in a dermatomal distribution of one or more adjacent sensory nerves.
 - Mildly painful in children

PHYSICAL EXAM

- Chickenpox
 - Evolution of rash from macules to vesicles, which appear as

- “dewdrop on a rose petal,” then crust
- Lesions in multiple stages of formation is pathognomonic.
 - Most children have less than 300 lesions; higher numbers are found among children who develop varicella after household contact.
 - New lesions appear for up to 7 days in otherwise healthy children.
 - Assess for complications: interstitial pneumonia, encephalitis, secondary bacterial infection (especially group A Streptococcus).
 - Zoster
 - Discrete vesicles appear first, then enlarge and coalesce.
 - New lesions cease to form after 3–7 days and crusting occurs within 2 weeks.
 - Severe local dermatomal infection, cutaneous dissemination, and visceral dissemination may occur in immunocompromised children.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Not needed for typical cases in healthy children
- VZV is difficult to isolate in cell culture.
- Immunohistochemical staining of epithelial cells from cutaneous lesions may provide a rapid diagnosis.
- PCR testing of clinical specimens must be done by experienced laboratory personnel.
- Serology is used to determine susceptibility to infection.
 - Acute and convalescent sera can determine acute infection: enzyme immunoassay (EIA), immunofluorescence assay (IFA), latex agglutination (LA), fluorescent antibody to membrane antigen (FAMA), and enzyme-linked immunosorbent assay (ELISA).

DIFFERENTIAL DIAGNOSIS

The differential diagnosis includes other causes of vesicular rash:

- Coxsackievirus infection (hand, foot, mouth)
- Eczema herpeticum
- Herpes zoster with dissemination
- Impetigo
- Insect bites
- Monkeypox

- Mycoplasma (erythema multiforme)
- Pseudomonas (ecthyma gangrenosum)
- Rickettsial pox
- Scabies
- Toxic epidermal necrosis, Stevens-Johnson, and various noninfectious vesicular conditions of the skin

TREATMENT

MEDICATION

- Acyclovir is the drug of choice for varicella or zoster in children.
- IV acyclovir is indicated for infected immunocompromised hosts and neonates and those with associated pneumonia or encephalitis:
 - <1 year old: 10–20 mg/kg q8h
 - ≥1 year old: 500 mg/m² q8h or 10–20 mg/kg q8h
 - ≥12 years old: 10 mg/kg q8h
- Treat for 7–10 days or until no new lesions for 48 hours.
- Oral acyclovir may be considered for those with increased risk of severe infection, including those with cutaneous disorders, chronic diseases that may be exacerbated by acute varicella infection, adolescents, and those who acquire infection after household contact.
 - Acyclovir (PO): 20 mg/kg q6h to max of 800 mg q6h, for 5 days
 - Valacyclovir (PO): (≥2 years old) 20 mg/kg (max 1,000 mg) q8h for 5 days; better bioavailability
- Children with VZV should not receive salicylates because of the risk of Reye syndrome. Use acetaminophen to control fever.

ADDITIONAL TREATMENT

General Measures

- Isolation of hospitalized patients with chickenpox:
 - Contact and airborne precautions of the index case for the duration of vesicular eruption and all vesicles crusted (usually 5 days, longer in immunocompromised patients)
 - Use negative-pressure rooms, if possible.
 - Exposed susceptible persons should be in contact and airborne

precautions from day 8 to 21 after the onset of rash in the index patient.

- Neonates born to mother with VZV: contact and airborne precautions until day 28
- Embryopathy does not require precautions if there are no active lesions.
- Persons who received VariZIG or IVIG should be kept in contact and airborne precautions for 28 days after exposure.
- Isolation of hospitalized patients with zoster:
 - Immunocompromised patients who have zoster (localized or generalized) and immunocompetent patients with disseminated zoster should remain in contact and airborne precautions for the duration of the illness, as above.
 - Immunocompetent patients with localized zoster: contact precautions until all lesions crusted.
- Isolation of outpatients with chickenpox:
 - Child should remain at home, away from susceptible and high-risk persons, until no new eruptions and all vesicles have crusted.
- Isolation of outpatients with zoster:
 - For immunocompetent patients with localized zoster, contact precautions are recommended until all lesions are crusted.
 - If lesions can remain completely covered, child may return to school; however, active lesions are infectious.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

For normal healthy individuals, follow-up is not necessary.

PROGNOSIS

- For most children, this childhood exanthema is a benign disease that lasts 6–8 days.
- Postherpetic neuralgia can cause significant morbidity following zoster in adults but is very rare in children.

COMPLICATIONS

Complications are associated with significant morbidity and may occur regardless of the use of acyclovir:

- Secondary bacterial infection—especially group A streptococcal infections and *Staphylococcus aureus*
- CNS (1 in 4,000): transverse myelitis, myelopathy, encephalitis (60 cases/year prevaccine), meningoencephalitis, acute cerebellar ataxia, necrotizing retinitis
- Varicella interstitial pneumonitis (more common in adults and infants)
- GI: pancreatitis, appendicitis, and hepatitis
- Heme: idiopathic thrombocytopenia, disseminated intravascular coagulation (hemorrhagic VZV)
- Nephritis
- Vasculopathy of small and large cerebral vessels, causing strokes
- Zoster sine herpete: radicular pain without rash but virologic confirmation of reactivation; can be dermatomal or CNS; very rare in the pediatric population
- Individuals with AIDS may have chronic VZV, including progressive myelopathy.
- Congenital varicella syndrome: characterized by limb atrophy and scarring of the extremity (cicatrices), CNS and eye manifestations
- Postherpetic neuralgia: Neuropathic pain is more common in zoster patients >60 years.
- Death: Varicella-related deaths continue to occur despite the recommended vaccine. Secondary bacterial infections and pneumonia are most frequent causes of death.

FAQ

- Q: What do you do for a patient on corticosteroids who has not had VZV and is exposed to VZV?
- A: Patients receiving ≥ 2 mg/kg/day or ≥ 20 mg/day of prednisone or its equivalent cannot be immunized with VZV vaccine. If the child is susceptible, has had sufficient exposure, and deemed at risk for serious infection, passive immunization with VariZIG or IVIG can be given.
- Q: Can children receiving inhaled steroids for asthma be immunized safely with VZV vaccine?
- A: Yes. Asthmatics on inhaled steroids can be safely immunized because the dose of inhaled steroid is not immunosuppressive.
- Q: For whom is VZV vaccine contraindicated?

- A: Immunosuppressed individuals, pregnant patients, infants <1 year old, and anyone who has a history of an allergic reaction to a vaccine component such as neomycin should not receive the VZV vaccine. Additionally, any child with a moderate to severe acute illness should have his or her VZV vaccination deferred until his or her illness has resolved. Patients with HIV infection can be vaccinated with VZV vaccine if their CD4+ T-cell percentages are $\geq 15\%$.
- Q: Can a child get shingles after vaccination with VZV vaccine?
- A: Yes. Zoster can occur following VZV vaccination. However, cases of shingles following vaccination tend to be milder and less frequent than after wild-type varicella.
- Q: What are the most common adverse effects of VZV vaccination?
- A: Mild local reactions are most common, occurring in 20–25% of vaccine recipients. 1–3% of children will develop a localized rash after vaccination, whereas 3–5% will develop a more generalized varicella-like rash. These rashes typically consist of 2–5 maculopapular or vesicular lesions and occur 5–26 days after vaccination.
- Q: What are the characteristics of breakthrough infection in a child who has been immunized with VZV vaccine?
- A: Breakthrough varicella can occur in children who have been appropriately immunized with VZV vaccine. Breakthrough infection is usually milder than that occurring in unimmunized children, often with fewer than 50 lesions, lower fever, and faster recovery. Although these children are less contagious than those with wild virus infection, they can transmit the virus to susceptible individuals.

CHILD ABUSE, PHYSICAL

Allison M. Jackson

BASICS

DESCRIPTION

Physical abuse is an act inflicted on a child or youth by a parent or caregiver resulting in mucocutaneous, musculoskeletal, visceral, or intracranial injury and/or death. Although a medical diagnosis, physical abuse is also defined legally in state statutes.

EPIDEMIOLOGY

Incidence

- Of those cases reported to child protective service agencies in the United States in 2011, 676,569 children were victims of abuse and neglect.
 - Child abuse rate was 9.1 per 1,000 children/year (2011 data).
 - 17.6% of abused children were found to be victims of physical abuse.
 - Over 1,500 child deaths were attributed to maltreatment in 2011, of which nearly 48% resulted from physical abuse.
- Abuse can happen in any family regardless of race, ethnicity, or socioeconomic class.

Prevalence

Not all child maltreatment is reported. In a nationally representative sample of over 4,000 children, more than 18% reported experiencing maltreatment in their lifetime.

GENERAL PREVENTION

- Assessing risk (parental history of mental illness or childhood victimization, parental substance abuse, economic stressors, difficult child temperament, unreasonable developmental expectations, children living with single mothers and an unrelated male)
- Screening for family violence (intimate partner violence)
- Providing anticipatory guidance regarding infant crying/toddler

- tantrums, toileting, and discipline techniques
- Nurse home visitation for at-risk families
- Parenting classes for all parents, although classes usually only target at-risk parents of young children

ETIOLOGY

- Although child abuse occurs in families regardless of race, ethnicity, or socioeconomic status, there are individual, family, community, and societal factors that place children at increased risk for maltreatment.
- Examples of risk factors include the following:
 - Difficult temperament
 - Parental history of childhood victimization
 - Parental substance abuse
 - Parental mental illness
 - Poverty and unemployment
 - Family violence

COMMONLY ASSOCIATED CONDITIONS

- Emotional abuse
- Neglect
- Sexual abuse
- Domestic violence exposure
- Chronic runaway status
- Domestic sex trafficking
- Posttraumatic stress disorder
- Depression
- Anxiety disorder

ALERT

Pitfalls

- Failing to consider abuse in the differential diagnosis of all pediatric trauma
- Failing to consider abuse in the differential diagnosis of all infants and toddlers with mental status changes (especially apparent life-threatening events [ALTEs]), even without bruising
- Failing to recognize the significance of subconjunctival hemorrhages and bruises in locations on the body atypical for accidental trauma

- Failing to consider trauma as a cause for bloody CSF
- Failing to consider alternative medical diagnoses in children for whom you suspect abuse
- Failing to document the history, physical findings, and assessment clearly

DIAGNOSIS

HISTORY

- As in all of medicine, the history is paramount to diagnosing child physical abuse. The history yields information useful in creating a timeline, determining plausibility of the injury event, and in formulating a differential diagnosis. Tips for gathering history when abuse is suspected:
 - Be curious but nonjudgmental.
 - Use open-ended, nonleading questions.
 - Speak with the verbal child and parent separately when abuse is suspected.
- Eliciting a narrative history about the injury event and the evolution of symptoms helps to establish a timeline and determine plausibility of the explanation. Asking, “Tell me what happened,” is the best place to begin. Eliciting achieved developmental milestones also aids in determining plausibility.
- In cases in which no injury event is reported, it is important to gather information of when the child was last well, how signs and symptoms evolved, and what prompted the caregiver(s) to seek medical attention.
- It is also important to elicit who was caring for the child at the time of the injury event or when the child became acutely and persistently ill. When children are verbal, ask them “what happened?” or “how did you get that?” regarding identified injuries.
- Past medical history, review of systems, and family history can also be helpful in formulating a differential diagnosis.

PHYSICAL EXAM

A comprehensive physical exam should be performed on any child for

whom maltreatment is suspected. Tips include the following:

- Plot growth parameters.
- Conduct a head-to-toe physical exam, including an anogenital exam.
- Suspicion for physical abuse is raised with injuries in the mouth (such as frenula injuries), subconjunctival hemorrhages, bruises in infants in locations atypical for accidental trauma (ears, neck, abdomen, buttocks, thighs), or cutaneous injuries with a pattern (e.g., loop marks, human bites).
- When head trauma is suspected, a dilated funduscopy exam should be completed by an ophthalmologist. Retinal hemorrhages that are in multiple layers of the retina and that extend to the ora serrata have a high specificity for inflicted head trauma.
- Not all injuries can be detected on physical exam; therefore, it is important to use other modalities to screen for other injuries.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- In patients with bruising or intracranial hemorrhage and/or a history or exam in which a bleeding disorder should be considered:
 - Urinalysis (UA) for myoglobinuria
 - Creatine kinase for muscle injury
 - Prothrombin (PT)/partial thromboplastin times (PTT) for prolonged bleeding
 - CBC with platelets for anemia and thrombocytopenia
 - Von Willebrand antigen and activity
 - Factors VIII and IX levels for hemophilia
 - Disseminated intravascular coagulation (DIC) panel
- In patients with multiple fractures, screen for metabolic bone disease:
 - Alkaline phosphatase
 - Calcium and phosphorus
 - 25-hydroxy vitamin D
 - Intact parathyroid hormone (PTH)
- To screen for abdominal trauma (bruising not usually present):
 - AST and ALT for liver injury
 - Amylase, lipase for pancreatic injury
 - UA for genitourinary injury

- In patients with altered mental status or concerns for poisoning:
 - Toxicology screen

Imaging

- To evaluate for skeletal trauma:
 - Skeletal survey for all children <2 years old with suspected abuse (occasionally useful in children 2–5 years old)
 - Fractures with high specificity for abuse include posterior rib fractures, classic metaphyseal lesions (i.e., bucket handle or corner fractures), scapular fractures, sternal fractures, and vertebral fractures.
 - A reported injury event that fails to mechanistically or developmentally provide a plausible mechanism should raise suspicions for abuse.
 - Radionuclide bone scans can augment the assessment for skeletal injury.
- To evaluate for head trauma:
 - CT of the brain and MRI of the brain and spine in children <1 year old or with signs or symptoms suggestive of head injury
 - Subdural hemorrhages are associated with abusive head trauma.
 - MRI may be helpful in assessing hemorrhages of different ages and, detecting brain injury and soft tissue neck trauma.
- To evaluate for thoracic, abdominal, and/or pelvic trauma:
 - CT chest, abdomen, and/or pelvis

Pathologic Findings

An autopsy by a qualified medical examiner should be completed when maltreatment is in the differential diagnosis.

DIFFERENTIAL DIAGNOSIS

Should be based on the physical exam, patient history, and family history

- Bruises
 - Trauma: accidental or inflicted
 - Dermatologic: congenital intradermal nevi, hemangiomas, phytophotodermatitis
 - Hematologic: hemophilia, platelet disorders, idiopathic thrombocytopenic purpura, leukemia

- Infectious: meningococemia
- Genetic: Ehlers-Danlos syndrome
- Congenital indifference to pain
- Cultural healing practices: coining (Cao gio), cupping, spooning (Quat sha)
- Vasculitis: Henoch-Schönlein purpura, hypersensitivity vasculitis
- Burns
 - Trauma: accidental or inflicted
 - Dermatologic: contact dermatitis, fixed drug reaction
 - Infectious: impetigo, staphylococcal scalded skin
 - Genetic: congenital indifference to pain
 - Cultural practices: moxibustion (burning moxa herb at therapeutic points on skin), Maquas (small deep burns at therapeutic points), garlic (used topically for infections)
 - Other: brown recluse spider bite
- Fractures
 - Trauma: birth, accidental, or inflicted
 - Metabolic: rickets, scurvy, copper deficiency, osteogenesis imperfecta, hypervitaminosis A, prostaglandin E toxicity
 - Neoplastic: leukemia, Langerhans cell histiocytosis, metastatic
 - Infectious: congenital syphilis, osteomyelitis
 - Other: infantile cortical hyperostosis
- Head injury
 - Trauma: accidental or inflicted
 - Hematologic disorder: late hemorrhagic disease of the newborn (vitamin K), clotting factor deficiencies, thrombocytopenia, platelet function disorder, Von Willebrand disease
 - Infectious: bacterial meningitis
 - Metabolic: glutaric aciduria type I

TREATMENT

GENERAL MEASURES

- Medical treatment according to injuries
- Report suspicions for physical abuse to the Child Protective Services

Agency in the jurisdiction of occurrence.

- Incorporate other disciplines into the treatment plan, in particular, social work and trauma-informed mental health care providers.

INPATIENT CONSIDERATIONS

Admission Criteria

- Primarily based on medical needs of patient
- For patient safety to allow for initial investigation to assess for a safe caregiver

Discharge Criteria

When medically prepared for discharge and a safe caregiver has been established by child welfare

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Reports will be investigated by the appropriate child welfare and/or law enforcement agency.
- The child may or may not be placed into foster care. In either case, if a child welfare case is opened, measures to monitor and strengthen the family and parents would be implemented. These measures are not always successful.
- Primary care and ongoing providers should monitor patients for physical and mental health sequelae of the abuse as well as ongoing abuse or neglect.

PROGNOSIS

Depends on nature and extent of injuries, the response of the child welfare and criminal justice system, and the timely implementation of medical and mental health services

COMPLICATIONS

- Death
- Intellectual disability
- Cerebral palsy

- Seizure disorder
- Learning disabilities
- Psychiatric disorders (depression, anxiety, posttraumatic stress disorder)

FAQ

- Q: When do I need to report child abuse?
- A: Whenever there is suspicion that your patient has experienced

maltreatment based on your clinical evaluation. You do not have to prove abuse; you just need to suspect it.

- Q: What happens when a report is taken?
- A: Many jurisdictions proceed with a multidisciplinary investigation. Investigators and attorneys may need to speak with you to clarify your findings and assessment.

CHLAMYDIA TRACHOMATIS INFECTION

Sumit Bhargava

BASICS

DESCRIPTION

Chlamydiae are obligate intracellular bacteria responsible for pulmonary infections, ocular trachoma, sexually transmitted diseases, and infections of the genital tract in the pediatric and adult population.

- The genus *Chlamydia* has 3 species known to affect humans:
 - *Chlamydia trachomatis*
 - *Chlamydia psittaci*
 - *Chlamydia pneumoniae*
- All 3 species can produce the clinical picture of the so-called atypical or interstitial pneumonia.
- *C. trachomatis* can cause afebrile pneumonia in 10–20% of infants born to infected mothers. Infected infants usually present prior to 2 months of age. Up to 50% of patients have a history of inclusion conjunctivitis.
- *C. psittaci* is mainly pathogenic for birds and occasionally affects humans, typically causing interstitial pneumonitis with associated fever, headache, malaise, and nausea.
- *C. pneumoniae* causes pneumonia, pharyngitis, sinusitis, and bronchitis in humans.

ALERT

- *C. trachomatis*
 - Infection can occur in infants delivered by cesarean section, even without rupture of amniotic membranes.
 - Ocular prophylaxis at birth does not reliably prevent conjunctivitis or extraocular infection, even if erythromycin ointment is used. Topical treatment alone is not recommended because it does not eradicate the nasopharyngeal colonization.

GENERAL PREVENTION

- Adequate surveillance and treatment of *C. trachomatis* colonizing the

genital tract of pregnant women is the best way of preventing disease in the infant.

- Annual chlamydia screening for all sexually active women younger than age 25 years and for all pregnant women in the 1st trimester of pregnancy is recommended.

EPIDEMIOLOGY

- *C. trachomatis*
 - There are at least 18 serologically distinct variants with different associations:
 - A–K: oculogenital
 - A–C: trachoma
 - B, D–K: genital and perinatal infection
 - L1–L3: lymphogranuloma venereum (LGV)
 - *C. trachomatis* is the most frequent cause of epididymitis in sexually active young men.
 - Incubation period: 5–14 days after delivery for conjunctivitis
 - The possibility of sexual abuse should be considered in older infants and children with vaginal, urethral, or rectal *C. trachomatis*.

Incidence

- This is the most common reportable sexually transmitted infection in the United States. The number of new infections exceeds 4 million annually.
- *C. trachomatis* is responsible for neonatal conjunctivitis, trachoma, pneumonia in young infants, genital tract infection, and LGV.
- Rates of infection in adolescent girls are 15–20%.
- 23–55% of all cases of nongonococcal urethritis in men are caused by *C. trachomatis*. Up to 50% of men with gonorrhea may be coinfecting with *C. trachomatis*.
- *C. trachomatis* pneumonia usually develops in infected infants <2 months of age (2 weeks to 5 months). The contagiousness of pulmonary disease is unknown, but is considered low.
- Half of the neonates born to infected mothers via vaginal delivery will acquire *C. trachomatis*. Conjunctivitis may develop in 30–50%.
- Pneumonia may develop in up to 30% of infants with nasopharyngeal

infection.

- Ocular trachoma caused by serovars A, B, Ba, and C is the most common cause of preventable blindness in the world, but is rare in the United States.

DIAGNOSIS

HISTORY

- Presents between 4 and 12 weeks of age
- Insidious onset
- Afebrile illness
- Rhinorrhea
- Repetitive cough
 - Staccato type in >50% of infants
 - Sometimes, pertussis-like coughing spells
- Conjunctivitis in up to 50% of infants
- Mild to moderate respiratory distress

PHYSICAL EXAM

- Afebrile
- 50% of patients will have conjunctivitis with discharge (can be seen up to several weeks after birth).
- Rhinitis with mucoid discharge or nasal stuffiness, sometimes causing significant airway obstruction
- Hypoxia is frequently present.
- Apneic episodes may be seen in preterm infants.
- Moderate tachypnea (50–60 breaths/min)
- Staccato cough
- Scattered rales on chest auscultation
- Wheezing is an uncommon finding.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Cell culture
 - Definitive diagnosis is by isolation of the organism in tissue culture.
 - Confirmation is by microscopy of the characteristic inclusions by

- fluorescent antibody staining.
- Specimens are obtained from the nasopharynx, conjunctiva, vagina, or rectum.
- Dacron polyester–tipped swabs should be used for collection.
- Nucleic acid amplification methods:
 - FDA-approved nucleic acid amplification methods such as polymerase chain reaction (PCR), strand displacement amplification (SDA), and transcription-mediated amplification (TMA) are more sensitive (98%) than cell culture and more specific and sensitive than DNA probe, direct fluorescent antibody (DFA), or enzyme immunoassay (EIA).
 - In addition, these have been approved for urine studies in both men and women, making them useful noninvasive tests for adolescents.
- Direct antigen tests:
 - DNA probe, DFA, and EIA are the most common nonculture direct antigen-detection tests approved by the FDA.
 - These are most sensitive (90%) and specific (95%) in conjunctival specimens.
 - These methods can have false-positive results when used for vaginal or rectal specimens.
- Serum antibody detection
 - Difficult to perform
 - Tests are not widely available.
- Eosinophilia of 300–400/mm³, hyperinflation, bilateral diffuse infiltrates on chest radiograph, and elevation of IgM (>110 mg/dL) and IgG (>500 mg/dL) are indirect evidence that indicate *C. trachomatis* pneumonia.
- Only culture should be used for sexual abuse or other forensic purposes.

Imaging

Chest radiography

- Hyperinflation with bilateral diffuse infiltrates

DIFFERENTIAL DIAGNOSIS

- Viral respiratory pathogens:

- Respiratory syncytial virus (RSV),
- Adenovirus
- Influenza A
- Influenza B
- Parainfluenza
- Other agents that can cause pneumonitis:
 - Cytomegalovirus
 - Pneumocystis carinii
 - Ureaplasma urealyticum
 - Bordetella pertussis

TREATMENT

MEDICATION

- Erythromycin, 50 mg/kg/day divided q.i.d. for 14 days (therapy is effective in 80–90% of cases). Additional topical therapy is unnecessary. An association between oral erythromycin and infantile hypertrophic pyloric stenosis (IHPS) has been reported in infants <6 weeks of age. Parents should be informed of the possible risk of IHPS and its signs.
- If the patient does not tolerate erythromycin, oral sulfonamides may be used after the immediate neonatal period. Children >8 years can be treated with tetracycline, 25–50 mg/kg/24 h divided q.i.d. for 7 days.
- A single 1-g oral dose of azithromycin may be used in children ≥ 45 kg or ≥ 8 years of age.
- In adults and adolescents, a single 1-g dose of azithromycin or doxycycline 100 mg b.i.d. orally for 7 days is 1st-line treatment.

ONGOING CARE

PROGNOSIS

- In general, good
- Infection with *C. trachomatis* has been associated with long-term respiratory sequelae, such as an increased incidence of reactive airway

disease and abnormal pulmonary function tests.

- Slow recovery
- Cough and malaise may persist for several weeks.

COMPLICATIONS

- 40% of women whose chlamydial infection is untreated develop pelvic inflammatory disease. 20% of these women may become infertile.
- Role of chlamydia in pathogenesis of asthma and atherosclerosis is under investigation.

CODES

ICD10

- A74.9 Chlamydial infection, unspecified
- P23.1 Congenital pneumonia due to Chlamydia
- A71.1 Active stage of trachoma

FAQ

- Q: If the mother has an untreated genital infection, should we treat the asymptomatic newborn?
- A: Yes. The child should receive oral erythromycin for 14 days.
- Q: Do we need to pursue the diagnosis of other sexually transmitted diseases?
- A: Yes. Gonorrhea, syphilis, hepatitis B, and human immunodeficiency virus infection need to be ruled out. If conjunctivitis is present, an ocular swab to exclude *Neisseria gonorrhoeae* infection must be included.
- Q: When do we need to suspect *C. trachomatis* pneumonia?
- A: In any infant <4 months of age who presents with cough, tachypnea, and rales on examination, when the chest radiograph shows bilateral infiltrates with hyperinflation

CHLAMYDOPHILA (FORMERLY CHLAMYDIA) PNEUMONIAE INFECTION

Amanda C. Schondelmeyer • Angela M. Statile

BASICS

DESCRIPTION

Chlamydiae are obligate intracellular organisms classified as bacteria, but which possess qualities of both bacteria and viruses. They cause a variety of infections from the respiratory to the urogenital tract. The genus has been divided into Chlamydia (*Chlamydia trachomatis*, others) and Chlamydophila (*Chlamydophila pneumoniae*, *Chlamydophila psittaci*, others). Three species are known to affect humans:

- *C. trachomatis*: a leading cause of sexually transmitted infections in the United States, which can be vertically transmitted during childbirth
- *C. pneumoniae*: an important cause of respiratory infections in the school-aged child
- *C. psittaci*: a zoonosis, primarily an avian pathogen, causing the disease psittacosis in exposed humans

EPIDEMIOLOGY

- Spread person to person by respiratory droplets; no specific seasonality
- Asymptomatic carriage and prolonged nasopharyngeal shedding occurs.
- Peak ages of infection are 5–15 years.
- Coinfection with other respiratory pathogens is common.
- Serum antibodies are positive in about 50% of adults by age 20 years.

RISK FACTORS

School-aged children are at highest risk.

GENERAL PREVENTION

Cough etiquette (coughing into elbow or tissue) and proper hand hygiene are important control measures.

PATHOPHYSIOLOGY

- Chlamydiae exist in two forms:
 - Elementary body (EB): infectious form
 - Reticulate body (RB): reproductive form
- Life cycle:
 - EB is taken into cell by endocytosis and reorganizes into a RB to replicate.
 - After replication, RB transformed to EB and are released by exocytosis or cytolysis.
 - Cycle between endocytosis and release is 2–3 days, explaining need for prolonged treatment.

DIAGNOSIS

HISTORY

- *C. pneumoniae* incubation period is approximately 21 days.
- Most commonly presents with prolonged cough (2–6 weeks), developing into atypical pneumonia
- Sore throat may precede onset of cough.
- Patients are mild to moderately ill; infection may be asymptomatic.
- Severe illness occurs in immunocompromised hosts.

PHYSICAL EXAM

- Nasal discharge
- Nonexudative pharyngitis
- Laryngitis, otitis media, and sinusitis may be present.
- Lung exam may be notable for wheezing and rales.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- No FDA-approved, reliable PCR test available.
- Serologic testing and culture are available, but empiric treatment is recommended.
- Other lab findings are nonspecific including the following:
 - Elevated liver enzymes
 - Left-shifted CBC without neutrophilia

Imaging

Chest radiography

- May have focal or diffuse infiltrates
- Pleural effusion may occur.

DIFFERENTIAL DIAGNOSIS

- Atypical pneumonia due to *Mycoplasma pneumoniae*
- Viral pneumonia
 - Influenza
 - Parainfluenza
 - Adenovirus
 - Respiratory syncytial virus (RSV)
- Less frequently
 - *Coxiella burnetii*
 - *Legionella pneumophila*

TREATMENT

MEDICATION (DRUGS)

First-line therapy is recommended based on national guidelines, as antimicrobial therapy is usually initiated empirically when suspicion is high for atypical pathogens. Alternative therapies are targeted at *C. pneumoniae*.

- First line
 - Azithromycin 10 mg/kg (max 500 mg) for 1 day followed by 5 mg/kg (max 250 mg) for 4 days
 - In hospitalized patients, if clinical picture may also be consistent with typical pathogens, add ampicillin IV 150–200 mg/kg/24 h divided every 6 hours or amoxicillin 90 mg/kg/24 h divided every 12 hours (max 4,000 mg/day) if tolerating oral medications.
- Alternatives:
 - If >8 years, doxycycline
 - Levofloxacin if unable to tolerate macrolides
- Appropriate length of antimicrobial therapy in *C. pneumoniae* infections is unclear.

ONGOING CARE

PROGNOSIS

For *C. pneumoniae*, full recovery is expected in general.

COMPLICATIONS

Immunocompromised individuals including those with cystic fibrosis and sickle cell disease can experience a fulminant course.

ADDITIONAL READING

CHOLELITHIASIS

M. Elizabeth Tessier • Eric H. Chiou • Kristin L. Van Buren

BASICS

DESCRIPTION

Cholelithiasis is defined by the presence of cholesterol and/or pigment stones in the gallbladder. Rare in infancy and childhood, it is usually found incidentally on an ultrasound. Risk factors in children include obesity, hemolytic disease, cystic fibrosis (CF), Crohn disease, and long-term total parenteral nutrition (TPN).

EPIDEMIOLOGY

- Cholelithiasis is relatively uncommon in childhood and adolescence; however, the incidence is increasing.
- Gallstones occurring in utero and in infancy have been described.
- Obesity is associated with up to 40% of the gallstones observed in all children and the majority of children with no underlying medical conditions. Obesity is estimated to increase the risk of gallstones in children by over 5-fold.
- Canadian Eskimos and Native Africans have the lowest risk of cholelithiasis.
- Native Americans, Swedes, Scandinavians, and Czechs have the highest risk.
- Pigment stones are more prevalent in prepubertal children, whereas cholesterol stones are predominant in adolescence and adulthood.

Incidence

- Prior to puberty, the incidence of gallstones is equal in males and females. After puberty, the incidence increases in females.

Prevalence

- The prevalence of cholelithiasis in children and adolescents reported in the literature is ~1.9–4.0%.
- In obese children, the prevalence is 2%.
- In children with sickle cell disease, the prevalence is 17–29%.

RISK FACTORS

- Acute renal failure
- Anatomic abnormalities (biliary stricture, duodenal diverticulum)
- CF
- Chronic hemolysis (sickle cell disease, thalassemia, spherocytosis, malaria)
- Chronic overnutrition with carbohydrate and triglyceride-rich, low-fiber diet
- Down syndrome
- Family history
- Female gender (>4 times higher odds than males)
- Hepatobiliary disease/cirrhosis
- Ineffective erythropoiesis (vitamin B₁₂ and folate deficiencies)
- Medications (estrogens, octreotide, clofibrate, furosemide, cyclosporine, ceftriaxone, oral contraceptives)
- Necrotizing enterocolitis
- Obesity
- Pregnancy/parity
- Prematurity
- Prolonged fasting/low-calorie diets/rapid weight loss (generally at least $\geq 10\%$)
- Severe Crohn disease of the ileum and/or ileal resection
- TPN
- Trauma/abdominal surgery or bariatric surgery
- Hispanic ethnicity

Genetics

- Mutations have been identified in genes encoding the ABC transporters for phosphatidylcholine (adenosine triphosphate-binding cassette, subfamily B), for bile salts (ABCB11), or for cholesterol 7 α -hydroxylase (CYP7A1), the CCK-A receptor (CCKAR), and the CF gene (CFTR).
- ABCB4 is also known as MDR3 (multidrug-resistant 3 glycoprotein). MDR3 is a phospholipid translocator in the hepatocyte membrane involved in biliary phosphatidylcholine excretion. MDR3 deficiency can cause severe neonatal liver disease, but mutations in MDR3 have

also been associated with cholelithiasis, cholestasis of pregnancy, and biliary cirrhosis.

- Variants of ABCG8 and UGT1A1 associated with bile acid metabolism and Gilbert syndrome are risk factors for cholelithiasis.
- Other gene polymorphisms are currently under investigation in humans.

GENERAL PREVENTION

Exercise and dietary modifications can decrease gallstone formation.

PATHOPHYSIOLOGY

- Bile is an aqueous solution of lipids with bile salts, phospholipids, and cholesterol. Changes in the proportion of bile constituents, nucleation (aggregation of cholesterol crystals), changes in gallbladder motility, or infection can lead to stone formation.
- Stone types: pigment, cholesterol, calcium carbonate, and mixed
- Black pigment stones are associated with increased unconjugated bilirubin:
 - Hemolytic diseases
 - Abnormal erythropoiesis
 - Enterohepatic circulation of unconjugated bilirubin
 - Ileal resection, Crohn disease
 - CF
- Brown pigment stones are associated with infection.
- The solubility of cholesterol in bile depends on bile salts and phospholipid concentrations. Cholesterol stones are associated with the following:
 - A decrease in bile salt pool
 - Decreased bile acid synthesis
 - Hypersecretion of cholesterol into the bile
 - Gallbladder stasis (weight loss, pregnancy, long-term TPN)
 - Increased biliary mucus secretion
 - Medications: furosemide, ceftriaxone, cyclosporine

DIAGNOSIS

HISTORY

- Gallstones in children are most commonly incidental findings on abdominal ultrasound.
- Biliary colic, pancreatitis, obstructive jaundice, cholangitis, or other complications should be excluded.
- Intolerance to fatty food rarely exists in children.
- The history should always include questions concerning
 - Previous episodes of right upper quadrant (RUQ) abdominal pain
 - Any risk factors for hemolysis
 - History of prematurity and necrotizing enterocolitis
 - Family history of cholelithiasis
 - Nutritional history
 - Medication use
 - Surgical history
 - Associated medical conditions (e.g., short gut syndrome, ileal disease)

PHYSICAL EXAM

- The physical exam may be completely normal or may uncover the acute abdomen of pancreatitis.
- Murphy sign (tenderness on palpation of the RUQ of the abdomen associated with inspiration) may be elicited in adolescents.
- Silent gallstones present coincidentally in infants and young children.
- Classic symptoms of RUQ pain (Murphy sign) and vomiting are more common in older children and adolescents.
- Younger children present with nonspecific symptoms including obstructive jaundice and mild elevation in transaminases.
- Fever is unusual in all age groups and often indicates the development of rare complications in children:
 - Cholecystitis
 - Choledocholithiasis
 - Cholangitis
 - Gallbladder perforation
 - Pancreatitis develops in 8% of patients with gallstones and is the most common complication.
 - Pancreatitis is more common in obese adolescents who have

undergone rapid weight reduction, as reported in the adult population.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Laboratory tests should include a complete blood count, urinalysis, amylase, lipase, fractionated bilirubin, alkaline phosphatase, γ -glutamyltransferase (GGT), and transaminase levels.
- Results should typically be within normal ranges.
- Abnormal results may suggest infection, obstruction, or another disease process.

Imaging

- Ultrasound
 - Diagnostic procedure of choice
 - Noninvasive with high sensitivity and specificity
- Plain radiography
 - May not be useful as the majority of gallstones in children are not radiopaque.
- Magnetic resonance cholangiopancreatography (MRCP) is useful to define anatomy in hepatobiliary disease and identify choledocholithiasis.

Diagnostic Procedures/Other

- Endoscopic retrograde cholangiopancreatography (ERCP)
 - Diagnostic for choledocholithiasis
 - Also therapeutic for removal of stones, stenting, or decompression of the biliary tree.
- Surgery should be considered for symptomatic patients.

Pathologic Findings

Black pigment stones are associated with hemolysis and cirrhosis. Brown pigment stones are typically mixed in composition, while cholesterol stones can vary from yellow to green or brown.

DIFFERENTIAL DIAGNOSIS

- Acalculous gallbladder disease
- Biliary dyskinesia

- Cholecystitis
- Common bile duct stones
- Congenital biliary anomalies
- Hydrops of the gallbladder (may be associated with Kawasaki disease)

TREATMENT

MEDICATION

- Spontaneous resolution in asymptomatic children is common, without the need for frequent medication use.
- Ursodeoxycholic acid (UDCA) suppresses hepatic cholesterol synthesis and secretion and can improve gallbladder muscle contractility by decreasing muscle cell cholesterol content in the plasma membranes.

ADDITIONAL TREATMENT

General Measures

- Primary prevention
 - High-fiber intake, diet low in saturated fatty acid and nuts, and moderate physical activity
 - Children with asymptomatic gallstones should only be observed.
 - During infancy, there is a chance for spontaneous stone dissolution, especially if cholelithiasis is linked to TPN.
- In children who are dependent on TPN and in patients with short-bowel syndrome, pseudoobstruction, inflammatory bowel disease, or a hemoglobinopathy, gallstones should be removed.
- Prevention of gallstone formation is done by treating underlying risk factors (small enteral feedings in addition to TPN, early pancreatic enzyme supplements in patients with CF, using alternative forms of contraception in high-risk populations, and weight control in obese infants and children with known hemolytic disease).
- Pigment stone formation increases with age.
 - Sickle cell patients should have the gallbladder removed when stones are identified.
 - This strategy will decrease the risk of cholecystitis and other

complications and will also help to differentiate between biliary colic and sickle cell crisis.

- Patients with a history of cholecystitis are at increased risk for further episodes (69% will have biliary colic within 2 years and 6% will require cholecystectomy).

SURGERY/OTHER PROCEDURES

- Laparoscopic cholecystectomy is the procedure of choice in symptomatic children.
- Lithotripsy using shock waves has not been approved for use in children.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Asymptomatic patients: Monitor for onset of symptoms; no use for repeat imaging or labs unless symptomatic.
- Symptomatic patients: Consider cholecystectomy.

- K80.21 Calculus of gallbladder w/o cholecystitis with obstruction
- K80.01 Calculus of gallbladder w acute cholecystitis w obstruction

FAQ

- Q: Does my child with CF have a greater problem with gallstones?
- A: Yes. Children with CF may have more frequent development of gallstones than children without CF. Reports of gallstones while on UDCA therapy have also been noted.
- Q: Why does my child with sickle cell disease have gallstones?
- A: Because the hemolytic process involves breakdown of hemoglobin, which produces bilirubin. This process may accelerate the formation of pigmented gallstones.
- Q: If my child has repeated attacks of RUQ abdominal pain and there are gallstones in the gallbladder, should he have surgery? What kind?
- A: Yes. Laparoscopic cholecystectomy is typically recommended.
- Q: Does obesity increase my child's risk of gallstones?
- A: Yes. Obesity is associated with up to 40% of the gallstones observed in all children.

CHOLERA

Matthew P. Kronman

BASICS

DESCRIPTION

Cholera is an acute-onset infection producing profuse secretory diarrhea with the potential for epidemic spread.

EPIDEMIOLOGY

- Diarrheal disease, including cholera, is the 2nd leading cause of mortality in children <5 years old worldwide.
- The first 6 recorded cholera pandemics occurred prior to 1923, but the current 7th pandemic began in 1961 and has continued through several waves of global transmission.
- Most cholera occurs in Asia and Africa, but *Vibrio cholerae* is now endemic in many countries. Regions previously free of cholera have become susceptible to severe outbreaks, as occurred in Haiti in 2010.
- In the United States, most cases result from travel. Cases have been reported in the Gulf Coast of Louisiana and Texas related to undercooked shellfish consumption.
- Case fatality rates are ~1% with timely treatment but can rise to 35–50% in severe cases in extremely resource-limited settings.

Incidence

- Although underreported, approximately 2.8 million cholera cases occur in endemic countries annually, with an additional 87,000 cases annually in nonendemic countries.
- An estimated 91,000 deaths occur in endemic countries annually.

Prevalence

Given the relatively short duration of illness and lack of chronic carrier state, cholera prevalence generally matches its incidence.

RISK FACTORS

- Inadequate drinking water and sanitation increase transmission; peri-

urban slums, refugee camps, disaster areas, etc., are high risk for cholera epidemics.

- Floods and surface water temperature changes lead to increased cholera density.
- Low gastric acidity (which decreases killing of ingested organisms), blood group O, and retinol deficiency are risk factors.
- Young children are at risk for severe cholera.

GENERAL PREVENTION

- Transmission
 - Hand washing after defecation and before food preparation is essential. Boiling or disinfection of water also prevents infection.
 - Thorough cooking of shellfish (which can be naturally contaminated) prevents infection.
 - During travel to endemic areas, avoid swimming or bathing in fresh water.
 - Report confirmed cholera cases to the local department of health.
 - Antibiotic prophylaxis of cholera contacts is debated but was shown in a meta-analysis to prevent disease among the contacts (relative risk, 0.35; 95% CI, 0.18–0.66), although the analysis noted a risk of bias.
- Vaccines
 - No vaccines are available in the United States.
 - Whole cell killed oral cholera vaccines have 52% (95% CI, 35–65%) efficacy in preventing cholera over the subsequent year, but protective efficacy is lower in children <5 years of age at 38% (95% CI, 20–53%).
 - Herd immunity occurs among unvaccinated people living near vaccinees.

PATHOPHYSIOLOGY

- Infection follows ingestion of large numbers of organisms from contaminated water or food (raw or undercooked shellfish and fish, or room temperature damp vegetables).
- The infectious dose for severe cholera is $\sim 10^8$ organisms but can be as little as 10^3 organisms in young children or those with decreased

gastric acidity (such as those on acid suppression or after certain meals).

- The typical incubation period is usually 2–3 days but ranges from ~12 hours to 5 days.
- 75% are infected asymptomatically; symptomatic illness ranges from moderate to severe.
- Cholera toxin is the key virulence factor responsible for the profuse watery diarrhea.
- Cholera toxin has 1 A and 5 B subunits.
 - The B subunits facilitate toxin attachment to intestinal cells.
 - The A subunit activates adenylate cyclase, increasing intracellular levels of cyclic adenosine monophosphate (cAMP), which causes chloride and sodium to be secreted into the gut lumen.
 - Water follows via osmosis.
- Severely ill patients can progress rapidly to dehydration, circulatory collapse, and death.
- Symptomatic patients may shed as many as 10^{10} – 10^{12} organisms per liter of stool and will shed organisms for 2 days to 2 weeks.

ETIOLOGY

- *V. cholerae* is a curved, motile gram-negative rod. Over 200 serogroups exist, but only serogroups O1 and O139 cause epidemics.
- *V. cholerae* serogroup O1 is divided into 2 biotypes: classical and El Tor. The classical biotype was formerly predominant, but the El Tor biotype is causing the 7th pandemic.
- *V. cholerae* serogroup O139 was first identified in 1992 and resembles the O1 El Tor biotype but possesses a distinct lipopolysaccharide and capsule.
- Humans are the only known host, but organisms can also exist freely in water, potentially contaminating fish and shellfish.

COMMONLY ASSOCIATED CONDITIONS

Cholera occurs in healthy individuals.

DIAGNOSIS

HISTORY

- Vomiting and profuse watery diarrhea: Severe illness is characterized by voluminous watery diarrhea (up to 1 L per hour) flecked with mucus (“rice-water stools”).
- Sick contacts with similar symptoms: Cholera epidemics can spread rapidly.
- Exposures
 - Return from travel within the last 5 days: Cholera is endemic in much of the world; the incubation period is typically 2–3 days.
 - Patient’s water source: Contaminated water serves as a reservoir.
 - History of inadequately cooked shellfish: Shellfish (e.g., oysters, crabs) can harbor the organism.

PHYSICAL EXAM

- Patients with cholera display signs of dehydration (tachycardia, dry mucous membranes, sunken fontanel or eyes, loss of skin turgor, lethargy) varying with severity.
- Arm and leg cramps occur due to secondary hypokalemia and hypocalcemia.
- Fever and obtundation secondary to hypoglycemia are more common in children.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Cholera is a generally clinical diagnosis.
- Electrolytes, BUN, creatinine, serum calcium, and glucose can be useful if available. Acidosis can occur from stool bicarbonate losses and lactic acidosis from poor perfusion.

Imaging

No imaging is required for diagnosis.

Diagnostic Procedures/Other

- Use selective media (thiosulfate citrate bile salts sucrose agar) to isolate *V. cholerae*. Alert the microbiology laboratory if culture testing for *V. cholerae* is desired.
- Serologic testing on acute and convalescent sera is also available

through the Centers for Disease Control and Prevention (CDC).

- Stool culture may not always be positive in suspected cases of cholera, and rapid dipstick methods to identify cholera toxin and lipopolysaccharide, direct fluorescent antibody assays, and polymerase chain reaction (PCR)–based diagnostic methods also exist and are being studied.

Pathologic Findings

Diagnosis can also be made with the identification of darting, curved bacilli in 400× darkfield microscopy of stool.

DIFFERENTIAL DIAGNOSIS

- Other *Vibrio* species can cause gastroenteritis (commonly caused by *V. parahaemolyticus* but also by *V. fluvialis*, *V. hollisae*, and *V. mimicus*) or wound infections and sepsis (*V. vulnificus*). Of these, only *V. parahaemolyticus* and *V. vulnificus* cause outbreaks.
- Additional intestinal bacterial pathogens include *Aeromonas*, *Campylobacter*, *Clostridium difficile*, *Escherichia coli*, *Listeria*, *Plesiomonas*, *Salmonella*, *Shigella*, *Vibrio* species, and *Yersinia*.
- Other viral and parasitic pathogens include amebiasis, adenovirus types 40 and 41, *Cryptosporidium*, *Cyclospora*, *Giardia*, norovirus, and rotavirus.

TREATMENT

MEDICATION

First Line

- Give antibiotics as an adjunct to fluid replacement for those with severe cholera.
 - Single-dose doxycycline in those >8 years of age
 - Alternately, single-dose azithromycin in children <8 years of age and pregnant women
 - Ciprofloxacin is another alternative.
- Single-dose azithromycin can reduce symptom duration by 50% and may reduce excretion of the organism to 1–2 days.
- *V. cholerae* isolates resistant to sulfonamides and tetracyclines are

common. Resistance to fluoroquinolones, macrolides, and β -lactams is increasingly reported.

- Administer zinc for 10–14 days: 10 mg/24 h for those <6 months of age and 20 mg/24 h for those 6 months to 5 years of age.
- Consider vitamin A supplementation for children in developing countries.
- Avoid antiemetics and antimotility agents.

ADDITIONAL TREATMENT

General Measures

- The mainstay of cholera treatment is rapid rehydration, accounting for both initial and ongoing fluid losses.
- Patients with moderate disease may require only oral rehydration solutions (ORS).
- Administer ORS in frequent small sips to those with vomiting. These solutions should contain at minimum 75 mEq/L of sodium to replete the significant sodium losses associated with cholera.
- ORS with total osmolality ≤ 270 mOsm/L is associated with increased risk of biochemical hyponatremia but not with other symptomatic outcomes compared to ORS ≥ 310 mOsm/L in a meta-analysis of a few existing trials.
- Those with more severe disease (volume loss >10%) require intravenous (IV) fluids.

ISSUES FOR REFERRAL

Specific follow-up is unnecessary.

ADDITIONAL THERAPIES

During outbreaks, rapid institution of improved sanitation and safe water availability are critical to decrease the extent of the outbreak.

INPATIENT CONSIDERATIONS

Initial Stabilization

Rapid correction of severe (>10%) dehydration is critical.

Admission Criteria

Admit those requiring IV fluids.

IV Fluids

- Dhaka solution is an optimal IV fluid containing dextrose and more bicarbonate and potassium than lactated Ringer (LR).
- LR is an acceptable, more available alternative; D5LR contains 5% dextrose.
- Normal saline lacks potassium and bicarbonate and is second-line.

Nursing

- Measure ongoing fluid losses carefully.
- Use contact precautions for infected infants and children who are incontinent of stool.

Discharge Criteria

Discharge rehydrated patients able to maintain hydration orally.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

In the untreated patient, the typical period of *V. cholerae* shedding is 1–2 weeks. Asymptomatic carriage is uncommon.

DIET

Resume a high-energy diet immediately after the initial fluid deficit is replaced. Infants should be encouraged to breastfeed.

PATIENT EDUCATION

- Improved sanitation and safe drinking water can help prevent future episodes.
- Secondary transmission can occur in households with affected members if strict hand washing and hygiene is not followed.

PROGNOSIS

For patients with prompt rehydration, the prognosis is very good regardless of whether antibiotic treatment is given.

COMPLICATIONS

- The main complications are those of severe dehydration: renal failure,

thrombosis, stroke, and cardiovascular collapse.

- Cholera itself causes no complications.

CODES

ICD10

- A00.9 Cholera, unspecified
- A00.0 Cholera due to *Vibrio cholerae* 01, biovar cholerae
- A00.1 Cholera due to *Vibrio cholerae* 01, biovar eltor

FAQ

- Q: What foods should I avoid while traveling?
- A: Foods associated with cholera include untreated or unboiled water and ice, undercooked fish and shellfish, raw vegetables, food from street vendors, and cooked food stored at ambient temperature.
- Q: Does cholera pose a risk to pregnant patients?
- A: Given the severe fluid losses, cholera can be life threatening to the fetus; fetal loss occurs in up to 50% of women in their 3rd trimester despite aggressive fluid resuscitation.
- Q: What is the risk of developing cholera among household contacts of

those with disease?

- A: Up to 50% of household contacts may develop diarrheal symptoms, typically within 2 days of exposure to the index case.

CHRONIC DIARRHEA

Roberto Gugig

BASICS

DESCRIPTION

- Diarrhea, defined as stool output >200 g/24 h in children and adults or 10 g/kg/24 h in infants, that has occurred for >30 days
- Can be characterized by pattern of stool output with regard to the following:
 - Volume
 - Frequency
 - Consistency
 - Gross appearance
- Should be differentiated from acute diarrhea, which is generally caused by enteric pathogens, is self-limiting, and has a duration of symptoms <14 days; as well as persistent diarrhea, which lasts 14–29 days

EPIDEMIOLOGY

- Gender and genetic factors do not play a significant role in most cases of chronic diarrhea.
- Chronic diarrhea seen in the tropics and developing countries is more likely infectious in nature than in the United States.

PATHOPHYSIOLOGY

The major categories are osmotic and secretory. Inflammatory and motility disorders are important subcategories to consider.

- Osmotic diarrhea occurs when unabsorbable solute accumulates in the lumen of the small intestine and colon, increasing intraluminal osmotic pressure and resulting in excessive fluid and electrolyte losses in stool.
 - Osmotic diarrhea will improve with fasting.
 - Osmotic diarrhea is usually related to malabsorption of dietary products or to the presence of congenital or acquired disaccharidase deficiency or glucose-galactose defects.
- Secretory diarrhea occurs when the net secretion of fluid and

electrolyte is in excess of absorption in the intestine:

- Secretory diarrhea occurs independently of the osmotic load in the intestinal lumen and does not improve with fasting.
- The mechanisms for secretory diarrhea include the activation of intracellular mediators such as cAMP, cGMP, and calcium-dependent channels.
- These mediators stimulate active chloride secretion from the crypt cells and inhibit the neutral coupled sodium chloride absorption.
- Inflammation in the intestine can cause an alteration in mucosal integrity resulting in exudative loss of mucus, blood, and/or protein. Increased permeability and altered mucosal surface area may affect absorption and result in diarrhea due to malabsorption.
- Motility disorders affect intestinal transit time. Hypomotility can allow stasis from bacterial overgrowth and can lead to diarrhea.

DIAGNOSIS

HISTORY

- Evaluation of the stool pattern, including consistency, frequency, and appearance
 - The characteristics of the onset of diarrhea should be noted as precisely as possible (e.g., congenital, abrupt, or gradual).
 - Overall duration of the diarrhea and pattern of intermittent versus continuous may also help in determining the underlying process.
 - Stool characteristics should be investigated. Specifically:
 - A history of blood and mucus in stool is strongly suggestive of inflammation.
 - Large-volume stools (>750 mL/24 h) imply small bowel disease and/or a secretory process.
 - Watery stools tend to be more associated with carbohydrate malabsorption, small bowel processes, medications, and functional processes.
 - Steatorrhea (fatty stools) can be greasy, oily, foul-smelling, and bulky and are usually associated with pancreatic disease, bacterial overgrowth, and short bowel syndrome.

- Epidemiologic factors (e.g., travel before onset of illness, antibiotic exposure, and illness in other family members) should be elicited.
- Dietary intake including the types of food and the occurrence of diarrhea in close relationship to specific foods (e.g., dairy products) may be diagnostic. The amount and type of liquid ingested may also be helpful in diagnosis.
- Nutritional status and growth parameters should be assessed. The presence of growth failure or malnutrition has considerable implications compared with a child with normal growth and no history of weight loss.
- Exposure to medications (antibiotics, laxatives, chemotherapeutic agents) or herbal therapies
- Iatrogenic causes of diarrhea should be investigated by obtaining a detailed medication history and history of radiation therapy and surgery.
- Other symptoms associated with the diarrhea are important to assess and include abdominal pain, fever, bloating, tenesmus, soiling, rashes, and joint complaints.
- The presence or absence of abdominal pain should be evaluated. Pain is often present in patients with inflammatory bowel disease, irritable bowel syndrome, and mesenteric ischemia.
- Family history (e.g., celiac disease, inflammatory bowel disease, cystic fibrosis, and other pancreatic processes)
- Previous evaluation should be reviewed whenever possible, objective records should be examined before new studies are ordered.

PHYSICAL EXAM

- Nutritional status: Compare height, weight, and head circumference with normal standards and previous exam measurements.
- Anthropometric measurements are important in assessing loss of body fat and muscle mass.
- Peripheral edema, ascites, rash, dystrophic nails, alopecia, chronic chest findings, and pallor may all be indicative of nutritional deficiencies secondary to chronic diarrhea.
- A rectal exam may reveal stool impaction with overflow diarrhea:
 - Is there blood in the stool?

- Perianal disease (fistula, skin tags, abscess)
- Evidence of infection should be considered with symptoms such as fever, bloody diarrhea, and vital sign instability.
- Aphthous lesions, arthritis, and clubbing
- The abdominal exam in most patients is generally nonspecific.
- Other features of diagnostic significance include rashes on the skin, mouth ulcers, thyroid masses, wheezing, arthritis, heart murmurs, hepatomegaly or abdominal masses.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Stool samples
 - Stool should be cultured for bacteria, ova and parasites, and viral organisms.
 - Clostridium difficile toxins A and B are heat-labile, and stool must be kept cool during transport.
 - Collect stool in the correct containers to ensure accurate and reliable analysis.
 - Stool samples can be tested for occult blood and for the presence of fecal leukocytes.
 - Stool pH and reducing substances
 - If stool is positive for reducing substances and/or the pH is <5.5, carbohydrate malabsorption with or without proximal small bowel injury is likely.
 - Note: Sucrose is not a reducing substance. If sucrose malabsorption is suspected, stool sample has to be hydrolyzed with hydrochloric acid and heat before analysis.
 - A positive Sudan stain of the stool is indicative of fat malabsorption. However, a 72-hour fecal fat collection remains the gold standard to diagnose fat malabsorption.
 - Stool for fecal elastase can be used to assess fat malabsorption.
 - Stool may be collected for electrolyte and osmolality measurements. Osmotic gap >100 mOsm/kg is indicative of an osmotic diarrhea.
 - Spot or 24-hour collection for fecal α_1 -antitrypsin can help assess protein loss.

- Stool collection for fecal calprotectin to assess for IBD—protein found in neutrophils that enter the bowel during an inflammatory process
- CBC
 - Hemoglobin and RBC may provide evidence and characteristics of anemia (i.e., microcytotic, macrocytotic, normochromic).
 - Leukocytosis suggest the presence of inflammation.
 - Eosinophilia can be seen with neoplasm, allergy, collagen vascular disease, parasitic infection, and eosinophilic gastroenteritis, or colitis.
- Other blood tests:
 - Prealbumin and albumin can provide parameters of protein and overall nutritional status.
 - Erythrocyte sedimentation rate and C-reactive protein (CRP) can serve as markers for inflammatory conditions.
 - Hormonal studies to assess for secretory tumors (vasoactive intestinal peptide [VIP], gastrin, secretin, urine assay for 5-HT)
 - In the evaluation for celiac disease, serum antitissue transglutaminase antibody and antiendomysial antibodies (presuming a normal level of total serum IgA)
 - Hepatic panel, coagulation profile, and fat-soluble vitamin levels (25-OH vitamin D; vitamins E, A, K) may be helpful to assess fat malabsorption.
 - Viral serologies such as HIV and cytomegalovirus need to be considered in the immunocompromised host with diarrhea.
 - Thyroid studies in patients with large-volume watery diarrhea
- Specialized studies:
 - A D-xylose absorption test is helpful in screening for small bowel injury. Timed serum D-xylose following oral ingestion is significantly lower in diseases causing diffuse mucosal damage to the small bowel (i.e., postviral enteropathy, celiac disease).
 - A hydrogen breath test may be helpful in evaluating for the possibility of small bowel bacterial overgrowth.
- Sweat chloride if cystic fibrosis is suspected

Imaging

- Plain radiograph studies usually not helpful; may demonstrate presence or absence of formed stool and/or fecal impaction
- Upper GI series with small bowel follow-through may show partial small bowel obstruction, strictures, or evidence of inflammatory bowel disease.
- Abdominal CT scan may help in assessing the pancreas for calcifications and inflammation.

DIAGNOSTIC PROCEDURES/OTHER

- Endoscopy with small bowel biopsy and small bowel aspirate for culture to help diagnose certain congenital, immunologic, or infectious causes of diarrhea
 - Small bowel disaccharidase studies will help detect carbohydrate malabsorption.
- Colonoscopy will diagnose colitis related to inflammatory bowel disease or infection.
- Video capsule endoscopy may also be used to further evaluate the small bowel for evidence of inflammation.

DIFFERENTIAL DIAGNOSIS

- Infants (<1 year of age)
 - Cow's milk and/or soy protein intolerance
 - Intractable diarrhea of infancy is associated with diffuse mucosal injury beginning at <6 months of age, resulting in malabsorption and malnutrition (sucrose and lactase deficiency).
 - Infectious/protracted postinfectious diarrhea
 - Microvillus inclusions disease
 - Tufting enteropathy
 - Autoimmune enteropathy
 - IPEX (immune dysregulation, polyendocrinopathy, enteropathy, X-linked)
 - Congenital glucose-galactose malabsorption
 - Hirschsprung disease with enterocolitis
 - Transport defects (e.g., congenital chloridorrhea)
 - Nutrient malabsorption (e.g., congenital glucose-galactose malabsorption and congenital lactase deficiency, sucrase-isomaltase

- deficiency)
 - Cystic fibrosis
 - AIDS enteropathy
 - Primary immune defects
 - Munchausen syndrome by proxy (factitious)
 - Drug-, toxin-induced
- Children (1–5 years of age)
 - Chronic nonspecific diarrhea of infancy (toddler's diarrhea)
 - Infectious/postinfectious enteritis
 - Giardiasis
 - Eosinophilic gastroenteritis
 - Sucrase-isomaltase deficiency
 - Tumors (neuroblastoma, VIPoma with secretory diarrhea)
 - Inflammatory bowel disease
 - Celiac disease
 - Cystic fibrosis
 - Small bowel bacterial overgrowth
 - AIDS enteropathy
 - Constipation with (overflow) encopresis
 - Acquired short bowel syndrome
 - Shwachman syndrome
 - Factitious
- Children (>5 years of age)
 - Similar to above
 - Acquired lactose deficiency (early adolescent)
 - Inflammatory bowel disease
 - Celiac disease
 - Constipation with (overflow) encopresis
 - Irritable bowel syndrome (adolescent)
 - Laxative abuse (adolescents)
 - Infection
- Bacterial (Aeromonas, Plesiomonas, Campylobacter, Salmonella, Mycobacterium tuberculosis, Yersinia, recurrent C. difficile)
- Viral (rotavirus, adenovirus, Norwalk virus, Norovirus)
- Parasites (Amoeba, Trichuris, Cryptosporidium, Giardia, Schistosoma,

Cyclospora)

- Small bowel bacterial overgrowth
- Tumors (neuroblastoma, VIPoma with secretory diarrhea)
- Primary bowel tumors (rare, adolescent)
- Complex congenital heart disease with protein-losing enteropathy
- Pancreatic insufficiency/chronic pancreatitis
- Hyperthyroidism
- Diabetes

TREATMENT

MEDICATION

- Presuming no inflammation or constipation, the use of antimotility agents such as loperamide and Lomotil, and antisecretory agents, such as octreotide, may have a role in noninfectious causes of diarrhea. However, identification and treatment of the underlying cause of diarrhea is always preferable.
- Pancreatic enzymes may be used in specific patients.
- Luminal (nonabsorbed) antibiotics for small bowel bacterial overgrowth

ALERT

- In certain cases in which the diet is altered as a therapeutic intervention, the physician must ensure that the patient is still absorbing adequate calories and micronutrients, so that the nutritional status of the patient is not further compromised.
- Avoid the reinstitution of a regular diet too quickly following a severe and/or protracted insult to the gut because this may further exacerbate the diarrhea.
- The use of antimotility and antisecretory agents should be judicious and as an adjunct to other therapy but not as the mainstay in the treatment regimen.
- In patients with cow's milk and/or soy allergy, rechallenge after 12 months of age in a controlled environment in case anaphylaxis occurs.
- Children with the following symptoms should see a health care

provider:

- Signs of dehydration
- Failure to thrive
- Diarrhea for more than 24–48 hours
- A fever of 102°F or higher
- Stools containing blood or pus
- Stools that are black and tarry

ADDITIONAL TREATMENT

- The first goal is to ensure adequate hydration status, nutritional intake, and to permit normal growth and development.
- Antibiotics when infection is suspected
- Many causes of congenital diarrhea do not have specific therapy available, and treatment is supportive.
- Diet: If infection is severe or protracted, an elemental formula may be necessary early in the recovery phase. If oral nutrition appears inadequate, the formula can be given in a slow, continuous fashion via a nasogastric/jejunal tube. Remove offending agent (e.g., cow's milk protein, soy protein, lactose, or gluten).
- In cases in which there is increased motility and thus rapid transit time, such as in chronic nonspecific diarrhea, alterations in the diet can be very helpful.
- Elimination of sorbitol-containing juices, which increases the osmotic load, and low-carbohydrate diet will help to lower the osmotic load delivered to the intestine. Furthermore, a high-fat diet will slow the intestinal transit time and increase the time available to absorb fluid, electrolytes, and nutrients from the intestinal tract.

FAQ

- Q: If my infant has cow's milk allergy, when can he have cow's milk?
- A: In patients with cow's milk and/or soy allergy, rechallenge should be around 12 months of age and should be in a controlled environment in case anaphylaxis occurs. If the testing is negative, ingestion of cow's milk can be recommended.
- Q: What are the best markers for success in management of chronic diarrhea?
- A: If weight and height normalize, the chances of continued malabsorption are unlikely.

CHRONIC GRANULOMATOUS DISEASE

Benjamin T. Prince • Ramsay L. Fuleihan

BASICS

DEFINITION

Chronic granulomatous disease (CGD) is a rare, primary immunodeficiency caused by a genetic defect that results in an inability of phagocytes to generate superoxide, which is important in microbial killing. Affected individuals are susceptible to recurrent, life-threatening bacterial and fungal infections.

EPIDEMIOLOGY

Incidence

1:200,000 to 1:250,000 live births in the United States and Europe. Rates in other countries vary depending on ethnic practices and degree of intermarriage.

RISK FACTORS

Genetics

- Mutations in any of the 5 genes that code for the 5 subunits of the phagocyte NADPH oxidase complex (phox) can result in CGD.
- Mutations in the gp91phox subunit are responsible for 65% of cases and are inherited in an X-linked manner (1/3 of these cases are the result of a de novo mutation).
- Mutations in p47phox, p22phox, p67phox, and p40phox subunits account for the remaining cases and have an autosomal recessive inheritance.
- Mutations in the p47phox subunit are the most common cause of autosomal recessive CGD (25% of all cases).

PATHOPHYSIOLOGY

- Phagocytes (neutrophils, monocytes, and macrophages) require NADPH oxidase to generate reactive oxygen species (ROS) in a process called the respiratory burst.

- During this process, the NADPH oxidase complex transfers an electron to molecular oxygen forming superoxide, which is eventually converted to hydrogen peroxide.
- Superoxide plays a significant role in killing bacterial and fungal pathogens both directly and through the activation of more important intraphagosomal proteases.
- The clinical phenotype of CGD is related to the level of residual superoxide production; patients who have higher levels of superoxide production have better long-term survival rates.
- Only the X-linked subunit gp91phox is phagocyte specific, and patients with defects in the autosomal subunits may also have other abnormalities such as vascular disease, diabetes, and inflammatory bowel disease.

ETIOLOGY

CGD is the result of a spontaneous or inherited genetic mutation that is present at birth.

DIAGNOSIS

HISTORY

- Patients most commonly present in early childhood with recurrent or severe bacterial or fungal infections of the lung, skin, lymph nodes, liver, bones, and blood.
- Patients may also have a history of failure to thrive, diarrhea, anemia, abnormal wound healing, or granulomatous inflammation.
- Infecting organisms are typically catalase producing; however, catalase alone does not appear to be a significant virulence factor in animal models.
- Most common organisms include *Staphylococcus aureus*, *Burkholderia* (*Pseudomonas*) *cepacia*, *Serratia marcescens*, *Nocardia*, *Aspergillus*, *Salmonella*, *Bacillus Calmette-Guérin* (BCG), *Mycobacterium*, *Klebsiella pneumoniae*, and *Candida*.
- Obtain a good maternal family history given that most common inheritance is X-linked. There may also be family history of lupus,

especially maternal.

PHYSICAL EXAM

- Skin and mucosa
 - Dermatitis, cellulitis, impetigo, abscesses, stomatitis, gingivitis
- HEENT
 - Conjunctivitis, chorioretinitis, sinusitis
- Lymphatic
 - Lymphadenopathy, suppurative lymphadenitis
- Respiratory
 - Pneumonia, pneumonitis
- Gastrointestinal
 - Gastric outlet obstruction hepatomegaly, splenomegaly, colitis, diarrhea, malabsorption, perirectal abscess, fistulae
- Genitourinary
 - Urethral strictures, urinary tract infections

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Dihydrorhodamine 123 (DHR) test
 - Uses flow cytometry to directly measure NADPH oxidase function in phagocytes
 - Phagocytes take up nonfluorescent DHR. Oxidation by a normal functioning NADPH oxidase complex causes DHR to fluoresce, which is identified by flow cytometry.
 - More sensitive and quantitative than older nitroblue tetrazolium (NBT) test
 - Can identify NADPH positive and negative subpopulations of phagocytes, easily identifying a carrier of CGD
 - May be falsely positive in patients with myeloperoxidase deficiency and SAPHO (synovitis, acne, pustulosis, hyperostosis, osteitis) syndrome
- NBT test
 - Historical test for CGD that is no longer widely used by immunologists
 - Neutrophils with a normal NADPH complex can reduce the dye,

resulting in a color change from yellow to dark blue. Neutrophils from patients with CGD cannot reduce the dye, and it remains colorless.

- Color change is assessed with microscopy, and results may be inaccurate if not performed by experienced technician.
- Genetic testing
 - A diagnosis of CGD should be confirmed with genetic testing to identify the specific genetic defect.
 - Identification of specific mutation can better predict the patient's clinical course.
 - Identification of specific mutation is necessary for a future prenatal diagnosis.

Imaging

Obtain chest radiograph, ultrasound, CT scan, or MRI as appropriate to aid in the diagnosis and evaluation of acute infections.

DIFFERENTIAL DIAGNOSIS

- Genetic/metabolic
 - Glucose-6-phosphate dehydrogenase (G6PD) deficiency
 - Glutathione synthetase (GS) deficiency
 - Cystic fibrosis
- Immunology
 - Myeloperoxidase deficiency
 - Hyper IgE syndrome
 - Humoral immunodeficiencies
 - IRAK4 deficiency
 - MyD88 deficiency
- Gastrointestinal
 - Inflammatory bowel disease

TREATMENT

MEDICATION

- Trimethoprim-sulfamethoxazole (TMP-SMX)
 - First line for antibacterial prophylaxis; also can be used for the

treatment of acute bacterial infections

- Prophylaxis dosing: 5 mg/kg/24 h TMP PO divided b.i.d., maximum 320 mg b.i.d.
- Has been shown to decrease frequency and severity of infections in CGD patients
- Itraconazole
 - First line for antifungal prophylaxis
 - Prophylaxis dosing: 5 mg/kg PO daily, maximum 200 mg daily
- Interferon gamma-1b
 - Effective in reducing the frequency and severity of infections when used prophylactically; however, it is unclear how much additional benefit is gained when used in conjunction with TMP-SMX and itraconazole prophylaxis
 - Prophylaxis dosing: 50 mcg/m² subcutaneously 3 times weekly
- Ciprofloxacin
 - Should be started prophylactically before any invasive procedure and continued for at least 24 hours afterward
 - Prophylaxis dosing: 7.5 mg/kg PO q12h, maximum 500 mg q12h
- Acute infections
 - Broad-spectrum IV antimicrobials: Severe infections should be treated empirically until a specific organism is identified. Treatment should cover both gram-negative and gram-positive bacteria along with fungi.
 - First line: TMP-SMX, fluoroquinolones, and voriconazole
 - Carbapenems, vancomycin, and amphotericin B may be considered depending on site or severity of infection.

ISSUES FOR REFERRAL

Factors that may help alert you to make a referral:

- New diagnosis of CGD
 - Immunologists can assist with antibiotic prophylaxis and with parameters for when to seek medical attention.
 - Can help establish the specific molecular diagnosis of the patient and offer genetic counseling for the future
 - Can discuss treatment options, including the possibility of hematopoietic stem cell transplant

- Fever or suspected infection
 - Patients with CGD tend to develop infections in unusual sites with unusual organisms. Both an infectious disease specialist and an immunologist can help with the evaluation and appropriate treatment of infections.
- Gastrointestinal symptoms or malabsorption
 - Gastroenterologists can help identify and treat strictures, obstruction, and colitis.
- The diagnosis of CGD should be considered in patients with
 - Recurrent lymphadenitis
 - Staphylococcal hepatic abscess
 - Infections with *Burkholderia cepacia*, *Serratia marcescens*, *Nocardia*, or *Aspergillus*
 - Salmonella sepsis
 - Perirectal or deep tissue abscesses
 - Colitis in infancy
 - Granulomatous lesions of the gastrointestinal or genitourinary systems

COMPLEMENTARY & ALTERNATIVE THERAPIES

- Hematopoietic stem cell transplant (HSCT)
 - HSCT can be a definitive cure for CGD.
 - Younger patients with absence of preexisting overt infection have the best prognosis.
- Gene therapy
 - May be an effective treatment of CGD in the future; however, currently still in research phase

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Regular screening blood tests
 - CBC with differential and LFTs should be performed every 6 months to monitor for any adverse effects of prophylactic

medications.

- CRP and ESR should be performed regularly and at times of acute infection.
- Pulmonary function testing should be followed annually to screen for chronic lung disease.
- Patients should be screened regularly by ophthalmology for chorioretinal lesions.
- Closely monitor CGD patients and carriers for signs of systemic lupus erythematosus and other autoimmune disorders.

PROGNOSIS

- CGD is a lifelong disease.
- Survival beyond the 4th decade is now common with antimicrobial prophylaxis and early and aggressive treatment of infections.
- Successful HSCT is curative.

COMPLICATIONS

CGD patients have an increased susceptibility to bacterial and fungal infections that usually are not pathogenic in normal hosts:

- Recurrent infections (see previous sections)
- Sepsis
- Chronic lung disease (secondary to recurrent infections)
- Chronic liver disease (secondary to recurrent infections)
- Chronic osteomyelitis of large and small bones
- Malabsorption
- Systemic and discoid lupus erythematosus
 - Increased incidence in female carriers

FAQ

- Q: Should patients with CGD receive dental prophylaxis?
- A: Yes. Antibiotic prophylaxis should be started before and continued for the 24 hours after any dental treatment likely to cause bleeding.
- Q: Can patients with CGD receive live viral vaccines?
- A: Yes. The only routine immunization that adults and children with CGD should NOT receive is BCG as it has been associated with disseminated infection.
- Q: Are all CGD patients with fever automatically admitted to the hospital?
- A: No. Although CGD patients are more prone to invasive and systemic infections, they are not necessarily admitted with every febrile episode. If there is evidence of a minor bacterial or viral infection without any concern for a more serious infection, patients may be treated as an outpatient with close monitoring. Subtle signs of an invasive infection must be taken very seriously.
- Q: Can CGD be diagnosed prenatally?
- A: Yes. Testing involves chorionic villus sampling; however, it can only be done on families with a history of CGD in which the specific

mutation is known.

CHRONIC HEPATITIS

Vani V. Gopalareddy

BASICS

DESCRIPTION

- Chronic hepatitis is a continuous inflammation of the liver that can lead to cirrhosis.
- Features include inflammation not caused by acute self-limiting infection or past drug exposure, with raised transaminases and histologic evidence of hepatitis.

EPIDEMIOLOGY

Depends on the cause of the underlying disease

- Nonalcoholic steatohepatitis (NASH) is a leading cause of elevated aspartate aminotransferase (AST)/alanine aminotransferase (ALT).
- Hepatitis B: common in immigrant children from Asia and Eastern Europe
- Hepatitis C: common in those who had blood transfusions and blood products before screening became available, history of IV drug abuse
- Wilson disease presents mainly in older children (>2 years of age) and adults.
- Autoimmune liver disease is more common in females and patients >6 months of age.
- Autoimmune hepatitis (AIH) may be associated with other autoimmune conditions such as diabetes, ulcerative colitis, autoimmune thyroiditis, and celiac disease.
- Cystic fibrosis and α_1 antitrypsin deficiency

PATHOPHYSIOLOGY

Pathology has been traditionally classified by evidence of chronic persistent hepatitis, chronic aggressive hepatitis, and chronic lobular hepatitis. All are associated with damaged hepatocytes as well as inflammatory cellular infiltration accompanied by liver regeneration.

- Chronic persistent hepatitis

- Minimal portal tract fibrosis
- Slightly widened portal tracts
- Limiting plate is intact and inflammation does not extend beyond this.
- No bridging fibrosis between portal tracts
- Chronic aggressive hepatitis
 - Perilobular hepatitis, with inflammatory cells extending from portal tracts into parenchyma with fibrosis
 - Piecemeal necrosis: necrotic hepatocytes surrounded by lymphocytes and fibroblasts
 - In advanced disease, fibrosis bridges the portal tracts (bridging fibrosis).
 - Cirrhosis occurs when there is loss of architecture owing to fibrosis.
- Chronic lobular hepatitis
 - Liver architecture is preserved with scattered changes of acute hepatitis with hepatocyte necrosis in the lobules (perivenular regions).
 - Associated with hepatitis B and non-A, non-B hepatitis

ETIOLOGY

- Autoimmune liver disease
- Viral hepatitis
- Obesity (NASH)
- Progressive familial intrahepatic cholestasis (PFIC) syndromes
- Congenital hepatic fibrosis
- Cystic fibrosis
- Metabolic disease
 - Mitochondrial disease
 - Lysosomal storage disorders
 - Peroxisomal disease
 - Lipid storage disease
 - Glycogen storage disease
 - Wilson disease and others
- Drug hepatotoxicity
 - Methotrexate
 - Isoniazid

- Thioguanine
- 6-Mercaptopurine
- Valproate
- Liver disease associated with other chronic diseases
 - Cardiac disease
 - Autosomal recessive polycystic kidney disease
 - Diabetes mellitus
 - Langerhans cell histiocytosis
 - Immunodeficiency
 - Total parenteral nutrition cholestasis

DIAGNOSIS

HISTORY

- Preceding clinical signs and symptoms for at least 6 months and complete medical history
 - History of blood transfusions
 - Surgery
 - Medications
 - Foreign travel
 - Social circumstances that predispose to liver diseases
- Symptoms of chronic illness can be nonspecific:
 - Poor growth
 - Intermittent jaundice
 - Abdominal pain
 - Bleeding
 - Malabsorption
 - Fever
 - Amenorrhea
 - Poor school achievement
 - Itching
- Variceal bleeding may be a presenting symptom in patients with portal hypertension.
- A history of jaundice in infancy, family history of liver disease or autoimmune liver disease, blood transfusions, IV drug use, or multiple

sexual partners can suggest an etiology of hepatitis.

PHYSICAL EXAM

Stigmata of chronic liver disease are as follows:

- Spider nevi, palmar erythema
- Dilated veins on abdomen/cutaneous shunts
- Palmar erythema
- Cyanosis (hepatopulmonary syndrome)
- Clubbing
- Jaundice
- Pruritus/scratch marks (due to accumulation of bile salts in the epidermis)
- Hypercholesterolemic xanthomas
- Enlarged liver or small, shrunken liver
- Splenomegaly
- Ascites
- Rickets
- Mental changes
- Feter associated with high ammonia
- Poor weight gain/FTT, weight loss

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- General liver testing: albumin, creatinine, γ -glutamyl transferase, AST, ALT, bilirubin, PT/INR, CBC, ammonia level
- Other testing as indicated by the specific clinical presentation
 - Viral serologies: hepatitis B, hepatitis C, hepatitis D
 - Autoantibodies: type 1: smooth muscle (also called antiactin), antinuclear, antisoluble liver antigen; type 2: liver kidney microsomal, primary sclerosing cholangitis: pericytoplasmic antineutrophil (p-ANCA)
 - Immunoglobulins: IgG elevated in autoimmune liver disease
 - Fasting glucose, insulin levels, CRP, lipid profile (suspected NASH)
 - α_1 Antitrypsin level and phenotype
 - Serum ceruloplasmin, serum copper, 24-hour urine copper (+/–

- penicillamine challenge), quantitative liver copper (Wilson disease)
- Cholesterol, triglycerides elevated in cholestatic syndromes, glycogen storage, Alagille syndrome, certain lysosomal disease, steatohepatitis
- Metabolic workup as indicated
- CPK level to rule out muscle source of elevated ALT/AST
- Urinary succinylacetone: tyrosinemia
- Urinary bile acids: bile acid synthetic defects
- Sweat test and cystic fibrosis genotyping
- Alpha fetoprotein (AFP) level
- Fibrosis markers (FibroSURE; FibroTest; ActiTest) are not validated for children but may be useful in older patients.

Diagnostic Procedures/Other

- Ultrasound with Doppler flow studies: should focus on liver and spleen and may detect steatosis
- Other testing as indicated by specific clinical presentation
 - MRI can demonstrate percentage steatosis.
 - FibroScan can measure liver stiffness/fibrosis.
 - Liver biopsy
 - Endoscopic retrograde cholangiopancreatography (ERCP) or magnetic retrograde cholangiopancreatography (MRCP) may be useful if primary sclerosing cholangitis is suspected.
 - Colonoscopy: sclerosing cholangitis, inflammatory bowel disease
 - Bone marrow aspirate to exclude Niemann-Pick type C or other storage disorders
 - Enzyme analysis to evaluate for lysosomal storage disease, glycogen storage disease
 - Angiography: congenital or acquired venous or arterial malformations, assessment of portosystemic shunt
 - Cardiac catheterization to assess pulmonary hypertension and cardiac status
 - Macroaggregated albumin scan to assess hepatopulmonary syndrome and hepatic encephalopathy
 - Muscle biopsy to assay respiratory chain enzymes in mitochondrial disorders

- Genotyping: Wilson disease, cystic fibrosis, and others

DIFFERENTIAL DIAGNOSIS

Nonhepatic etiologies of lab or physical exam abnormalities

- Hepatomegaly: elevated right-sided cardiac pressures, such as patients with Fontan operations, right-sided heart failure; respiratory diseases with lung hyperexpansion
- Splenomegaly
 - Blood malignancies
 - Storage diseases
 - Hematologic disease with hemolysis
 - Infection
 - Vascular
- Jaundice: often confused with hypercarotenemia
- Elevated transaminases: consider nonhepatic sources such as skeletal muscles in myopathies; with jaundice, consider hypopituitarism in infancy
- Alkaline phosphatase: may be elevated in growing children and in rickets; may not indicate biliary obstruction
- γ -Glutamyl transferase
 - Produced in renal tubules, pancreatic and biliary ducts
 - Often elevated in patients on antiepileptic drugs and in alcoholics
- Abnormal coagulation: anticoagulant medications, bacterial overgrowth with malabsorption, inherited disorders of coagulation, sepsis

TREATMENT

GENERAL MEASURES

The management of patients is dictated by the underlying diagnosis.

- General management
 - Maintaining growth and development is paramount.
 - Fat-soluble vitamins (A, D, E, K) given orally are poorly absorbed in cholestasis, and levels must be monitored.
 - Anthropometric parameters must be recorded, including skinfold

thickness.

- Body mass index
- Preference for medium-chain triglyceride (MCT)–rich formulas can reduce fat malabsorption.
- Branched-chain amino acids may be useful in patients with hepatic encephalopathy.
- Ursodeoxycholic acid: choleretic
- Encourage bolus feedings; minimizing continuous feeding and total parenteral nutrition may reduce gallbladder sludge.
- Proactive involvement of clinical psychologist and play therapist can help alleviate problems such as depression and fear.
- Aggressive weight management in patients with obesity/hypermetabolic syndrome with steatohepatitis; curbing passive activities such as television, computer games
- Chronic debilitating pruritus: indication for liver transplantation after failure of medical therapy. Treatment for pruritus includes the following:
 - Actigall (ursodeoxycholic acid)
 - Rifampicin
 - Ondansetron
 - Antihistamines
 - Naltrexone
 - Zoloft
 - Cholestyramine
 - Ultraviolet light
- Monitoring portal hypertension: Assessment of portal flow on ultrasound and spleen size may provide some indication of disease progression.
- Treatment of recurrent cholangitis may decelerate the progression of liver disease.
- Aggressive treatment for spontaneous bacterial peritonitis in patients with ascites
- Early referral to a liver transplant center
- Complete immunization schedule including hepatitis A, hepatitis B, and annual flu shots.

- Specific management depends on the underlying liver disease.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Look for hepatocellular carcinoma developing in patients with chronic liver disease.
- Obtaining an ultrasound scan of liver and AFP every 6 months is considered a reasonable schedule.
- Advise patients with splenomegaly to wear a spleen guard and avoid activities (e.g., contact sports) that can cause splenic rupture.

PROGNOSIS

Some cases of chronic hepatitis are associated with diseases that are treatable. Others are progressive and not amenable to treatment. A subset of patients will progress to end-stage liver disease and require liver transplantation.

CODES

ICD10

- K73.9 Chronic hepatitis, unspecified
- K73.0 Chronic persistent hepatitis, not elsewhere classified
- B18.9 Chronic viral hepatitis, unspecified

FAQ

- Q: What are the risks of providing very young patients with a liver transplant?
- A: Lifetime risks of immunosuppression and rejection. Although transplant in the very young is more difficult, with the increased use of split liver techniques and improved use of immunosuppressives, outcomes of orthotopic liver transplantation in infants have improved.
- Q: Why should we be aggressive with vitamin supplementation?
- A: Chronic hepatitis is associated with significant malabsorption of vitamins A, D, E, and K. Vitamins D and E deficiencies in particular can cause rickets and neuropathy.
- Q: How can I optimally administer oral supplements of vitamins in the very young?
- A: It is common practice in some centers to give vitamins D and E as an intramuscular injection on a monthly basis, with levels done in between.
- Q: Why do jaundiced children scratch?
- A: The accumulation of bile salts causes pruritus.
- Q: What stigmata of chronic liver disease can be seen in children?
- A: Spider nevi, liver palms (palmar erythema), splenomegaly, cutaneous shunts, and clubbing are very common.

CHRONIC KIDNEY DISEASE

Madhura Pradhan • Susan L. Furth

BASICS

DESCRIPTION

- The Kidney Disease: Improving Global Outcomes (KDIGO) 2012 clinical practice guidelines defines chronic kidney disease (CKD) as abnormalities of kidney structure or function, present for >3 months (except in infants <3 months of age) with implications for health.
- Criteria for CKD include the following:
 - Markers of kidney damage such as albuminuria, urine sediment abnormalities, electrolyte and other abnormalities due to tubular disorders, abnormalities detected by histology, structural abnormalities detected by imaging, and history of kidney transplantation
 - Decreased glomerular filtration rate (GFR) <60 mL/min/1.73 m²
- CKD is classified based on cause, GFR category, and albuminuria category.
- GFR categories
 - G1: GFR ≥90
 - G2: GFR 60–89
 - G3a: GFR 45–59
 - G3b: GFR 30–44
 - G4: GFR 15–29
 - G5: GFR <15
- Albuminuria categories—albumin to creatinine ratio in mg/g
 - A1 <30
 - A2 30–300
 - A3 >300

EPIDEMIOLOGY

Incidence

~5–12 cases per year per million of age-related population

Prevalence

Prevalence of CKD has been reported to be between 21 and 74 cases per million of age-related population from various studies in Europe and Latin America.

RISK FACTORS

- Risk factors for congenital renal disease include genetic and environmental factors (maternal diabetes, exposure to medications such as ACE inhibitor/NSAIDs)
- Low birth weight, prematurity, and rapid weight gain in early childhood increase risk of CKD.
- Hypertension and proteinuria increase risk of CKD progression.

PATHOPHYSIOLOGY

- Low nephron mass: leads to hyperfiltration injury
- Cardiovascular: Hypertension secondary to activation of renin-angiotensin system, fluid overload, and anemia from erythropoietin deficiency contribute to cardiovascular morbidity.
- Bone and mineral bone disorder of CKD: Decreased synthesis of vitamin D_{1,25} OHD leads to hyperparathyroidism and bone disease.
- Growth: Metabolic acidosis, anemia, and perturbations in the growth hormone insulin-like growth factor-1 (GH-IGF-1) axis lead to poor growth.

ETIOLOGY

- Congenital anomalies of kidney and urinary tract (CAKUT) constitute ~60% of cases of childhood CKD and include the following:
 - Renal dysplasia/hypoplasia
 - Obstructive uropathy (posterior urethral valves, prune belly syndrome)
- Cystic and hereditary disorders
 - Autosomal recessive and dominant polycystic kidney disease
 - Juvenile nephronophthisis (cystic)
 - Alport syndrome, cystinosis, oxalosis, congenital nephrotic syndrome (hereditary)
- Glomerular diseases
 - Focal segmental glomerulosclerosis (FSGS)

- Hemolytic uremic syndrome (HUS)
- Systemic lupus erythematosus (SLE)
- IgA nephropathy
- Others—membranoproliferative glomerulonephritis (MPGN), membranous nephropathy, pauci-immune glomerulonephritis

COMMONLY ASSOCIATED CONDITIONS

Several syndromes have associated anomalies of the kidney and urinary tract such as DiGeorge syndrome, Alport syndrome, Alagille syndrome, branchio-oto-renal syndrome, Townes-Brocks syndrome, and Bardet-Biedl syndrome.

DIAGNOSIS

HISTORY

- Past history
 - Birth history for oligohydramnios, perinatal events
 - Recurrent urinary tract infections (UTIs)
 - Enuresis
- Family history
 - Renal disease
 - Hearing impairment

SIGNS AND SYMPTOMS

- Poor growth
- Poor appetite
- Fatigue, malaise
- Headache (if hypertensive)
- Polyuria (in congenital abnormalities)
- Oliguria

PHYSICAL EXAM

- General
 - Short stature
 - Decreased weight for age
 - Pallor

- Fetid breath
- Elevated blood pressure (BP)
- Head, ears, eyes, nose, and throat
 - Retinal changes
 - Presence of preauricular tags, branchial cysts
 - Hearing deficit
- Chest
 - Rales
- Heart
 - Flow murmur
 - Gallop
 - Pericardial rub
- Abdomen
 - Palpable kidneys
 - Suprapubic mass
- Extremities
 - Rachitic changes
 - Edema
- Neurologic system
 - Developmental delay
 - Altered mental status
 - Hypotonia
 - Irritability

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Serum chemistries: azotemia, hyperkalemia, acidemia, hypocalcemia, hyperphosphatemia, elevated alkaline phosphatase
- CBCs: normocytic anemia with low reticulocyte count (CKD stage 3, GFR <60)
- Urinalysis: isosthenuria, proteinuria, hematuria
- Intact parathyroid hormone: elevated
- 25-vitamin D: often low
- GFR measurement
 - Inulin clearance is the gold standard for GFR measurement but is not practical. A simple and commonly used method to estimate GFR

in children >1 year of age with CKD is the CKiD bedside equation, an update to the traditional Schwartz formula.

- The calculation is already corrected for surface area and does not require a urine collection: $\text{height (cm)} \times 0.413$ correction factor/ Pcreat in mg/dL .

Imaging

- Chest x-ray: pulmonary edema, cardiomegaly
- Bone films: delayed bone age, rickets, osteomalacia, osteitis fibrosa
- Renal ultrasound: small echogenic kidneys, cystic kidneys, hydronephrosis

Diagnostic Procedures/Other

A renal biopsy is indicated for diagnosis of acquired or glomerular kidney diseases such as FSGS. It is not necessary when there is radiologic evidence of structural/congenital cause of CKD such as small or echogenic kidneys.

DIFFERENTIAL DIAGNOSIS

- Differentiate acute kidney injury from CKD
- Usually, CKD is insidious and associated with poor growth, delayed puberty, rickets, polyuria, and anemia. The kidneys may be small on renal ultrasound.

TREATMENT

MEDICATION

- Phosphate binders (e.g., calcium carbonate, calcium acetate, sevelamer; avoid aluminum)
- 1,25-dihydroxy vitamin D and/or 25-hydroxy vitamin D
- Alkali therapy (e.g., sodium bicarbonate/citrate)
- Antihypertensive therapy
- ACE inhibitors (renoprotection)
- Recombinant erythropoietin
- Ferrous sulfate (if iron deficient)
- Recombinant human growth hormone

ADDITIONAL TREATMENT

Renal replacement therapy (dialysis/renal transplantation) is indicated when GFR is <10 mL/min/1.73 m² or when medical management fails to control signs/symptoms of CKD.

ISSUES FOR REFERRAL

Pediatric primary care physicians should observe patients with CKD in consultation and with assistance from a pediatric nephrologist.

COMPLEMENTARY & ALTERNATIVE THERAPIES

Treatment of hypertension, proteinuria (with ACE inhibitor/angiotensin receptor blocker [ARB]), and dyslipidemia delays progression of CKD.

ALERT

During episodes of gastroenteritis, infants with CKD may be prone to dehydration because they have obligatory polyuria due to a concentrating defect. Do not use urine output level or specific gravity of urine as indices for hydration. If hospitalized, fluid levels considered “maintenance” may be insufficient due to polyuria.

SURGERY/OTHER PROCEDURES

- Transplantation: In some cases, a preemptive transplant may be offered instead of dialysis.
- Consider arteriovenous fistula or graft placement for patients who will require long-term hemodialysis.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

Children with CKD need close outpatient follow-up every 1–3 months, depending on the level of GFR to monitor BP, growth, and lab tests.

DIET

Restrictions mandated by condition

- Phosphate
- Potassium

- Sodium (indicated if patient has edema/hypertension)
- Fluid (indicated in conditions related to oliguria)

PROGNOSIS

Prognosis of CKD depends on the cause of CKD. CKD progression leads to need for renal replacement therapy. Prognosis of children with renal transplantation is excellent with 5-year survival of >85%.

COMPLICATIONS

- Growth retardation is particularly severe when CKD develops in the 1st year of life. Growth failure may be secondary to poor nutrition, bone disease, acidosis, or a direct effect on the GH-IGF-1 axis.
- Mineral and bone disorders may be seen early in association with CKD, manifesting with growth failure, bowing of the lower extremities, and slipped epiphysis. Vitamin D deficiency and secondary hyperparathyroidism are the major factors leading to bone disease.
- Anemia develops secondary to decreased erythropoietin secretion and decreased erythrocyte survival. The anemia is a normocytic variant associated with a low reticulocyte count.
- Cardiovascular disease including left ventricular hypertrophy (LVH) and coronary artery disease often develops in early adulthood. Uncontrolled hypertension, anemia, hyperlipidemia, and hyperparathyroidism all contribute to this leading cause of death in adults with CKD.
- Neurodevelopmental delay increases in children with CKD. This is probably due to uremic effects on the development of the brain.
- Hypertension may be seen in some patients with CKD due either to hyperreninemia or hypervolemia.
- Platelet abnormalities, protein-calorie malnutrition, and immunologic disturbances are also seen in patients with uremia.

CODES

ICD10

- N18.9 Chronic kidney disease, unspecified
- Q63.9 Congenital malformation of kidney, unspecified
- N18.3 Chronic kidney disease, stage 3 (moderate)

FAQ

- Q: Which OTC medications should be avoided in children with CKD?
- A: NSAIDs, pseudoephedrine (if patient hypertensive), enemas containing phosphate, and antacids containing magnesium or aluminum should not be taken.
- Q: Can children with CKD receive immunizations?
- A: Children with CKD should especially receive all necessary immunizations because some vaccines are contraindicated after transplantation. In some cases, booster immunizations are necessary because of an inadequate response to the initial series (e.g., hepatitis B virus, measles, mumps, rubella; varicella). Additionally, children with CKD should receive the polyvalent pneumococcal vaccine after age 2 years.
- Q: When is recombinant human erythropoietin indicated?
- A: Generally, this medication should be considered when the hematocrit level is <33% (Hgb <11.0 g/dL).

CIRRHOSIS

Rima Fawaz

BASICS

DESCRIPTION

- Cirrhosis is the end stage of progressive hepatic necrosis, fibrosis, and regenerative nodule formation that may occur as a result of many different liver diseases.
- Results in distortion of liver architecture and compression of hepatic vascular and biliary structures
- In its advanced form, cirrhosis is irreversible and often requires liver transplantation for survival of the patient.

EPIDEMIOLOGY

- There are varying causes of cirrhosis; accordingly, no specific epidemiologic pattern can be identified.
- Cirrhosis due to chronic HCV infection, alcoholic liver disease, and nonalcoholic fatty liver disease (NAFLD) are the most common indications for liver transplantation in adults.
- Biliary cirrhosis due to biliary atresia is the most common indication for liver transplantation in children.

Genetics

- Many distinct genetic disorders can cause cirrhosis, such as Wilson disease and hereditary hemochromatosis.
- Human leukocyte antigen (HLA) associations have been identified in several autoimmune disorders, including sclerosing cholangitis and autoimmune hepatitis.

DIAGNOSIS

HISTORY

- Compensated (latent) cirrhosis: asymptomatic, with no signs or symptoms of liver disease. Discovered incidentally either during

routine physical examinations with an enlarged liver and/or palpable spleen or as a result of an investigation for an unrelated condition

- Decompensated (active) cirrhosis: As cirrhosis progresses, overt signs and symptoms may occur including failure to thrive, muscle weakness, fatigue, jaundice, pruritus, edema, abdominal pain, ascites, steatorrhea, spontaneous bleeding (i.e., epistaxis) or bruising, and deterioration in school performance or depression.
 - In adults, decompensated cirrhosis is defined by the development of major complications: variceal hemorrhage, ascites, spontaneous bacterial peritonitis, hepatic encephalopathy, hepatorenal syndrome, hepatopulmonary syndrome, and portopulmonary hypertension.
- Based on the varying etiologies, one should elicit pertinent historical features characteristic of specific problems:
 - Exposure to infectious hepatitis, antecedent viral illnesses
 - Exposure to hepatotoxins
 - Family or personal history of genetic, metabolic, or autoimmune diseases
 - Neurologic problems, deteriorating school performance, depression (Wilson disease)

PHYSICAL EXAM

- General: poor growth, malnutrition, fever, cachexia, obesity (NAFLD)
- Skin: jaundice, flushing, pallor, cyanosis, palmar erythema, spider angiomas, fine telangiectasia (face and upper back), easy bruising
- Abdomen: ascites (distention, fluid wave, shifting dullness), caput medusa (prominent periumbilical veins), splenomegaly, rectal varices, hepatomegaly, or a shrunken liver
- Extremities: digital clubbing, hypertrophic osteoarthropathy, muscle wasting, peripheral edema
- Endocrine: gynecomastia, testicular atrophy, delayed puberty
- Central nervous system: asterixis, positive Babinski sign, mental status changes, hyperreflexia, muscle wasting
- Eyes: Kayser-Fleischer rings (Wilson disease)

DIAGNOSTIC TESTS & INTERPRETATION

Lab

Can be useful in determining the etiology and the severity of liver disease prior to a liver biopsy

- Tests of liver cell injury: alanine aminotransferase (ALT), aspartate aminotransferase (AST), lactic dehydrogenase (LDH)
- Tests of synthetic function: albumin and other serum proteins, prothrombin time (PT), international normalized ratio (INR), partial thromboplastin time (prolonged in severe liver disease), ammonia, plasma and urine amino acids, serum lipids and lipoproteins, cholesterol and triglycerides
- Tests of cholestasis: fractionated bilirubin, alkaline phosphatase, γ -glutamyltransferase, cholesterol, serum and urine bile acids
- Tests of fibrosis: Serum markers may be useful to evaluate hepatic fibrosis noninvasively; however, these are still being investigated for clinical use.
- Miscellaneous disease-specific serum tests:
 - Viral serologies: hepatitis B, hepatitis C, other viruses
 - Wilson disease: serum ceruloplasmin, 24-hour urine copper, and slit-lamp exam for Kaiser–Fleischer rings
 - α_1 -Antitrypsin deficiency: α_1 -Antitrypsin serum level and protease inhibitor (Pi) phenotype
 - Autoimmune hepatitis: autoantibodies (antinuclear, anti-smooth muscle, anti-liver/kidney microsomal, anti-F-actin), serum immunoglobulins
 - Hemochromatosis: serum iron, total iron binding capacity, ferritin
 - Metabolic/genetic: fasting blood sugar, lactate, pyruvate, uric acid, sweat test, carnitine, creatine phosphokinase (CPK), porphyrins, serum amino acids, urine organic acids, urine reducing substances, urine succinylacetone, fatty acid degeneration products, α -fetoprotein

Imaging

- Ultrasound with Doppler images: Evaluate for anatomy of the liver and biliary tree and vessels, presence of ascites, signs of portal hypertension such as splenomegaly, varices, reversal of flow in portal vein.
- Hepatobiliary radioisotope scanning: Assess biliary patency in neonatal

cholestasis.

- Cholangiography (magnetic resonance cholangiopancreatography [MRCP]: Assess for intra- and extrahepatic biliary disease (stones, choledochal cyst, sclerosing cholangitis).
- Angiography: CT or magnetic resonance angiography to evaluate for vascular anatomy and portosystemic shunts
- Noninvasive assessment of liver fibrosis: CT, MRI, elastography by ultrasound or MRI

Diagnostic Procedures/Other

- Liver biopsy
 - Percutaneous needle biopsy, intraoperative wedge biopsy, transjugular liver biopsy
 - Confirm the presence (stage), activity (grade), and type of cirrhosis.
 - Various hepatic diseases that progress to cirrhosis have characteristic histologic findings. However, the process of cirrhosis may obscure the nature of the original insult, rendering morphologic and histologic classifications unhelpful.
- Hepatic venous pressure gradient (HPVG): rarely used in children but is the most accurate prognostic indicator of outcome in adults with cirrhosis.
- Cholangiography
 - Intraoperative cholangiography: Assess for extrahepatic biliary atresia in neonates.
 - Endoscopic retrograde cholangiopancreatography (ERCP): Assess for extrahepatic biliary disease in older patients where MRCP is not helpful or therapeutic interventions possible (i.e., stent placement).

DIFFERENTIAL DIAGNOSIS

- Biliary
 - Extrahepatic biliary atresia
 - Choledochal cyst
 - Tumors
 - Common bile duct and biliary lithiasis
 - Alagille syndrome
 - Biliary hypoplasia

- Sclerosing cholangitis
- Graft-versus-host disease
- Vanishing bile duct syndrome due to drugs (e.g., trimethoprim–sulfamethoxazole)
- Langerhans cell histiocytosis
- Hepatic
 - Infectious hepatitis, including viral hepatitis B, C, D, other viruses
 - Autoimmune hepatitis
 - Nonalcoholic steatohepatitis (NASH)
 - Drugs/toxins and alcohol
- Genetic/metabolic (examples for each category, not a complete list)
 - Cystic fibrosis
 - α_1 -Antitrypsin deficiency
 - Congenital hepatic fibrosis
 - Progressive familial intrahepatic cholestasis (PFIC)
 - Wilson disease
 - Hereditary hemochromatosis
 - Carbohydrate defects: galactosemia, hereditary fructose intolerance, glycogen storage III and IV
 - Amino acid defects: tyrosinemia
 - Lipid storage diseases: Gaucher disease, Niemann-Pick type C
 - Mitochondrial disorders: fatty acid oxidation defects, respiratory chain defects
 - Peroxisomal disorders: Zellweger syndrome
 - Porphyrrias: erythropoietic protoporphyria
- Vascular
 - Budd-Chiari syndrome
 - Veno-occlusive disease
 - Congestive heart failure

TREATMENT

MEDICATION

First Line

- Fat-soluble vitamin supplementation: vitamins A, D, E, and K

- Diuretic therapy (furosemide, spironolactone) for patients with ascites
- Albumin infusions for patients with refractory ascites
- β -blockers have been shown to decrease portal pressure and reduce the risk of variceal bleeding in adults with portal hypertension.
- Antibiotics, if suspicious for spontaneous bacterial peritonitis (avoid nephrotoxic agents)
- Lactulose and rifaximin (adults) are used for patients with hepatic encephalopathy.

SURGERY/OTHER PROCEDURES

- Endoscopic variceal band ligation or sclerotherapy for variceal GI bleeding
- Paracentesis for refractory ascites or diagnosis of spontaneous bacterial peritonitis
- Portosystemic shunt placement (surgical or radiologic transjugular intrahepatic portosystemic shunting [TIPS] procedure) for complications of uncontrolled portal hypertension
- Liver transplantation

ONGOING CARE

DIET

- Malnutrition is common in chronic liver diseases because of several metabolic derangements, fat malabsorption, anorexia, and increased energy requirements.
- Adequate caloric intake is critical and, often, will require supplemental nasogastric tube feedings.
- Some of the dietary fat should be provided as medium-chain triglycerides, which do not require bile for absorption.
- Fat-soluble vitamin levels should be monitored and supplemented, if necessary.
- Careful attention must also be paid to fluid and electrolyte balance; sodium restriction (<2 mEq/kg/day) may be necessary in the presence of ascites.

General Measures

Spleen guard and avoidance of abdominal trauma if significant splenomegaly

PROGNOSIS

- The prognosis for cirrhosis leading to decompensation depends on the underlying cause.
- The underlying condition should be treated when possible (e.g., Wilson disease, autoimmune hepatitis).
- Poor prognostic features in children include prolonged INR unresponsive to vitamin K, ascites, malnutrition, low plasma cholesterol, elevated bilirubin level, and presence of hepatorenal syndrome.

COMPLICATIONS

- Malnutrition and growth failure
- Malabsorption (diarrhea, steatorrhea, fat-soluble vitamin deficiencies)
- Portal hypertension and variceal bleeding
- Chronic gastritis, peptic ulcer disease, gastroesophageal reflux
- Ascites
- Encephalopathy
- Hypersplenism (associated with anemia, thrombocytopenia, and neutropenia)
- Anemia
- Coagulopathy
- Hepatopulmonary syndrome (hypoxemia, cyanosis, dyspnea, digital clubbing)
- Hepatorenal syndrome (rapidly progressive renal failure in patients with cirrhosis)
- Bacterial infections, spontaneous bacterial peritonitis
- Hepatocellular carcinoma

CODES

ICD10

- K74.60 Unspecified cirrhosis of liver
- K74.5 Biliary cirrhosis, unspecified
- Q44.2 Atresia of bile ducts

FAQ

- Q: Will my child with cystic fibrosis develop cirrhosis?
- A: The medical literature suggests a 5–10% incidence of cirrhosis in children with cystic fibrosis. Children with cystic fibrosis liver disease who develop cirrhosis are at risk for complications of portal hypertension.
- Q: Will every child with cirrhosis need a liver transplant?
- A: If cause of cirrhosis cannot be treated, most children who develop cirrhosis will ultimately require a liver transplant.

CLEFT LIP AND PALATE

Oksana A. Jackson • Jesse A. Taylor

BASICS

DESCRIPTION

- Cleft lip
 - Deformity of the upper lip that may include a discontinuity of vermillion, skin, muscle, and mucosa as well as the underlying gingiva and bone
 - May be unilateral or bilateral
 - A complete cleft extends into the nose. An incomplete cleft has a bridge of intact tissue between the oral and nasal cavities.
- Cleft palate
 - May involve the gingiva, hard palate, and/or soft palate
 - Represents a visible separation between the 2 halves of the roof of the mouth, involving mucosa, muscle, and often the bones of the hard palate
 - A submucous cleft palate has intact mucosa, but the underlying muscle and bone are at least partially divided.

EPIDEMIOLOGY

Incidence

- Incidence of cleft lip with or without cleft palate is approximately 1 in 700 births.
- Incidence of cleft lip with or without cleft palate increases with parental (especially paternal) age >30 years. Some association with low socioeconomic class may be nutrition related.

Prevalence

- Racial heterogeneity noted in cleft lip and palate (Asians, 2.1 in 1,000 births; whites, 1 in 1,000; blacks, 0.41 in 1,000)
- Isolated cleft palate is present in 1 in 2,000 births across races.
- Gender heterogeneity noted in Caucasians (male-to-female ratio: cleft lip with or without cleft palate, 1.5–2:1; cleft palate only, 0.7:1)

Genetics

- 1/3 of patients with cleft lip and/or cleft palate have a positive family history; positive family history is noted twice as often in cleft lip with or without cleft palate compared to cleft palate alone.
- The recurrence risk for cleft lip with or without cleft palate is 4% if one 1st-degree relative is affected and 9% if two are affected.
- Some recognized patterns of malformation that include cleft lip and/or cleft palate may be caused by exposure to teratogens, but there is little evidence linking isolated clefts to exposure to any single teratogenic agent.
 - Exceptions include phenytoin (use during pregnancy has been associated with a 10-fold increase in the incidence of cleft lip) and isotretinoin (~26 relative risk of congenital malformations including cleft palate).
- Incidence of cleft lip in infants born to mothers who smoke during pregnancy is twice that in those born to nonsmoking mothers.

PATHOPHYSIOLOGY

- Muscle fibers are atrophic and disorganized in the region of the cleft.
- Mitochondrial abnormalities are noted at the cleft margins by histochemical and electromyographic studies.

ETIOLOGY

- Cleft lip may result from failure of the medial nasal and maxillary processes to join in utero or possibly from lack of adequate mesenchymal reinforcement, leading to subsequent breakdown and separation.
- Cleft palate results from failure of the palatal shelves to fuse.
- Prenatal dietary supplementation with folic acid and vitamin B₆ has led to lower-than-expected incidence of cleft lip and cleft palate and to a decreased incidence of neural tube defects.
- Bilateral cleft lip is associated with cleft palate in 86% of cases. Unilateral cleft lip is associated with cleft palate in 68% of cases.
- Cleft lip/cleft palate is more common on the left, particularly in boys.

COMMONLY ASSOCIATED CONDITIONS

- Most clefts are nonsyndromic and may be either multifactorial in origin

- or the result of changes at a major single-gene locus
- Over 400 genetic syndromes are associated with facial clefts.
 - Among patients with clefts of the secondary palate alone, syndromes associated with microdeletions of chromosome 22q11.2 are currently the most common syndromic diagnoses.
 - Collectively known as 22q11.2 deletion syndrome, includes velocardiofacial syndrome, DiGeorge syndrome, and conotruncal anomaly face syndrome
 - Inheritance is autosomal dominant with considerable variability in phenotypic expression, which may include facial dysmorphism, developmental delay, cardiovascular anomalies, immunologic abnormalities, cleft palate, and velopharyngeal dysfunction.
 - Next most common syndrome associated with palatal clefts is Stickler syndrome:
 - Characterized by autosomal dominance, cleft palate, epicanthal folds, flat facies, joint hyperflexibility, severe myopia, retinal detachment, and glaucoma
 - Caused by a mutation of the gene for type 2 collagen (chromosome 12q)
 - Most common syndrome associated with clefts of the lip and/or palate is Van der Woude syndrome (autosomal dominant, lower lip pits, IRF6 mutations, 1q32)
 - Other genetic syndromes associated with cleft lip and/or palate:
 - CHARGE (Coloboma of the eye, Hear defects, Atresia of the choanae, Retardation of growth and/or development, Genital and/or urinary abnormalities, and Ear abnormalities and deafness) syndrome has an autosomal dominant pattern of malformation with majority of patients having CHD7 microdeletion or mutation.
 - EEC (ectrodactyly–ectodermal dysplasia, cleft) syndrome is associated with p63 gene mutations.
 - Smith-Lemli-Opitz (defect in cholesterol synthesis, DHCR7 gene mutation, 7q34)
 - Pierre Robin sequence is a condition usually associated with a wide U-shaped cleft palate.
 - Characterized by a small mandible, retropositioned tongue, and

- subsequent upper airway obstruction
- May occur in infants with or without genetic syndromes (Stickler most common)

DIAGNOSIS

HISTORY

- Prenatal exposure to alcohol, cigarettes, phenytoin, and isotretinoin
- Family history of cleft lip or cleft palate
- Speech problems in 1st-degree relative

PHYSICAL EXAM

- Incomplete or complete cleft of lip, alveolus, hard and soft palate, or uvula. Soft palate and uvula clefts are always midline, whereas lip, alveolar, and hard palatal clefts can be unilateral or bilateral.
- A bifid uvula or a notch in the bone at the posterior hard palate may indicate a submucous cleft.
- A small mandible and repositioned tongue may indicate a risk for airway obstruction (Pierre Robin sequence).
- Look for associated anomalies of the face, heart, and extremities that may indicate a clefting syndrome.
- Tricks
 - Examine the palate from the top of the patient, with the head in your lap, using a tongue depressor and flashlight.
 - Palpate the posterior hard palate for a possible notch in the bone.
 - Palpate the gums and maxilla for a possible notch in the floor of the nose.

DIAGNOSTIC TESTS & INTERPRETATION

- Hearing evaluation
- Complete ophthalmologic examination to check for myopia, glaucoma, and retinal detachment and rule out Stickler syndrome
- Pulse oximetry to check for desaturation while feeding or while supine
- Polysomnography to distinguish central from obstructive apnea.
Increased serum 7-dehydrocholesterol and decreased serum cholesterol to rule out Smith-Lemli-Opitz syndrome

- Karyotype to rule out specific genetic abnormalities
- Fluorescence in situ hybridization to rule out a chromosome 22q11.2 deletion
- Echocardiography, renal ultrasound, and endocrine laboratory studies if indicated

Imaging

- Prenatal diagnosis of cleft lip is reliable by ultrasound; prenatal diagnosis of cleft palate remains unreliable by ultrasound. 3-D ultrasound has improved the reliability of prenatal diagnosis.
- Fetal MRI provides excellent soft tissue definition and can be used when the diagnosis is uncertain on ultrasound or to better delineate the severity of the cleft.
- After birth, no additional radiologic imaging is indicated in patients with isolated cleft lip and/or palate.

TREATMENT

GENERAL MEASURES

Airway management

- Prone positioning if the tongue is causing airway obstruction
- Plastic surgery and ENT consultation if airway obstruction persists

ORTHODONTICS

Preoperative orthodontics may include obturators to facilitate feeding and speech, nasoalveolar molding and lip taping to narrow the cleft and reshape the nose before lip repair, palatal expansion prior to bone grafting, conventional orthodontics including braces, maxillary appliances, prosthetic teeth, bridgework, and maxillary and/or mandibular distraction to advance the mid- or lower face.

SURGERY/OTHER PROCEDURES

- Significant airway obstruction and desaturation in the neonatal period refractory to prone positioning may indicate the need for a tongue–lip adhesion, release of the floor of the mouth musculature, mandibular distraction, or tracheostomy.

- Wide clefts of the lip may benefit from either nasoalveolar molding or preliminary lip adhesion at 2–3 months of age. Timing of definitive lip repair varies from 2 to 6 months of age.
- Palate repair is generally done at <1 year of age to decrease speech and language difficulties.
- Otitis media is more common with cleft palate, and bilateral myringotomy tubes can be inserted at the time of cleft repair.
- Correction of secondary deformities may include the following:
 - Lip scar revision
 - Cleft nasal deformity correction (infancy to adulthood)
 - Alveolar bone grafts (usually when permanent canines are erupting, age 6–10 years)
 - Pharyngoplasty for soft palate–velopharyngeal incompetence (childhood–adolescence)
 - Closure of palatal fistulas
 - Orthognathic surgery for severe jaw deformities (after facial growth is complete)

Admission Criteria

Airway obstruction or severe feeding difficulties in the neonate

Discharge Criteria

- Stable airway
- Tolerating feedings

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Multidisciplinary team for routine visits from infancy to adolescence:

- Pediatrician
- Plastic surgeon
- Speech pathologist
- Orthodontist
- Pediatric dentist
- Otolaryngologist
- Oral surgeon

- Psychologist
- Social worker
- Anthropologist (facial growth specialist)
- Geneticist
- Support groups

DIET

- Cleft patients may have significant feeding problems because of an inability to generate negative intraoral pressure necessary to feed efficiently.
- Preemie nipples with enlarged or cross-cut openings, or soft plastic squeezable bottles, can facilitate milk flow.
- Specially designed cleft bottles are commercially available.
- Poor weight gain may necessitate nasogastric tube feedings.

PROGNOSIS

Very good. Most patients undergo normal growth and development. Long-term follow-up by a multidisciplinary team and parental support are critical for optimal outcomes.

COMPLICATIONS

- Airway obstruction and feeding disorders, particularly with Pierre Robin sequence
- Chronic otitis media
- Speech problems, including hypernasality and articulation errors
- Associated malformations
 - ~1/3 of patients with cleft palate has associated anomalies, with isolated cleft palates having the highest. CNS, cardiac, and urinary tract malformations and clubfoot are commonly associated with clefting.
- Potential problems
 - Hypernasal resonance and nasal air emission during speech may indicate velopharyngeal incompetence or palatal fistula. 8–30% of patients may require additional palatal or pharyngeal surgery following initial palate repair.
 - Multiple ear infections may require prolonged use of myringotomy tubes to prevent hearing impairment. Audiograms should be

obtained regularly.

- Delays in speech and language development may require detailed evaluation, early intervention programs, and speech therapy.
- Poor dentition, occlusal problems (crossbite), gingivitis, and crowding
- Learning disabilities are increased in children with clefts.
- Behavior disorders and psychosocial adjustment disorders
- ~25% of affected individuals will manifest maxillary hypoplasia that requires jaw surgery to correct occlusal abnormalities.

ALERT

- Failure to diagnose airway obstruction in infants with Pierre Robin sequence may lead to failure to thrive or, in severe cases, death.
- Failure to diagnose associated anomalies may lead to missed syndromes and inaccurate genetic counseling.
- A submucous cleft palate can be easily missed until hypernasal speech is noted later in life.

CODES

ICD10

- Q37.9 Unspecified cleft palate with unilateral cleft lip
- Q36.9 Cleft lip, unilateral
- Q35.9 Cleft palate, unspecified

FAQ

- Q: Will there be a scar?
- A: All cleft lip repairs will leave some type of permanent scar, with potential asymmetry that may benefit from later additional lip scar revision or additional nasal surgery.
- Q: What is the goal of surgery?
- A: Goal is to create a lip that does not attract undue attention.
- Q: What is the most difficult part of surgery?
- A: The nose is often the most difficult to correct because of asymmetry in cartilage and skin contour.
- Q: Will my child be able to speak clearly?
- A: Most children will achieve velopharyngeal competence and normal speech but may require additional speech therapy to achieve this goal.
- Q: Is cleft palate inherited?
- A: For nonsyndromic cleft lip with or without cleft palate:
 - Risk of having a second child with a cleft, if neither parent has a cleft: 4%
 - Child's risk of later having a child with a cleft: 4%
 - Risk of having a third child with a cleft, if parents have 2 affected children but neither parent is affected: 9%
 - Risk of having a second child with a cleft, if 1 parent also has a cleft: 17%
 - For nonsyndromic isolated cleft palate:
 - Risk of having a second child with a cleft, if neither parent has a cleft: 2%

- ▣ Child's risk of later having a child with a cleft: 3%
- ▣ Risk of having a third child with a cleft, if parents have 2 affected children but neither parent is affected: 1%
- ▣ Risk of having a second child with a cleft, if 1 parent also has a cleft: 15%

CLUBFOOT

Richard S. Davidson

BASICS

DESCRIPTION

Clubfoot is a congenital or neuromuscular deformity in which the hindfoot is fixed in equinus (plantar flexion) and varus (toward the midline) and the forefoot is fixed in varus, equinus, and often cavus (high midfoot arch with overextension).

EPIDEMIOLOGY

- Risk of deformity increases by 20–30 times when there is an affected 1st-degree relative.
- Male > female (2:1)

Incidence

Incidence is 1–1.4/1,000 live births but can vary among different ethnic groups.

PATHOPHYSIOLOGY

- Many anatomic abnormalities have been postulated as causing clubfoot:
 - Anomalous or deficient muscles, myoblasts, mast cells, abnormal primary bone formation, joint and muscle contractures, vascular anomalies (absent dorsalis pedis artery), and nerve anomalies
 - Abnormalities of the fibrous connective tissue
- Interruption of embryonic foot development has also been suggested.

ETIOLOGY

- Most cases are idiopathic (multifactorial inheritance pattern with significant environmental influence).
- Infrequently, neuromuscular imbalance may underlie the deformity (cerebral palsy, myelomeningocele, lipomas of the cord, caudal or sacral agenesis, polio, arthrogryposis, fetal alcohol syndrome).
- Rapid recurrence should prompt a thorough examination for possible

underlying etiologies.

DIAGNOSIS

HISTORY

- Family history of clubfoot (3%)
- Onset of deformity (congenital or developmental)

PHYSICAL EXAM

- Careful examination of
 - The neuromuscular system for neuromuscular etiologies such as lumbosacral sinuses, dimples, and lipomas as well as spasticity, asymmetry, and muscle imbalance
 - The hips for hip dysplasia
 - The neck for torticollis
- Physical exam trick
 - Push the foot into a corrected position. Is the deformity fully correctable? Overcorrectable?
 - About 1 in 15 idiopathic clubfeet have rigid equinus, midfoot (metatarsal) plantarflexion, a deep heel crease at the posterior ankle, a transverse midsole or midfoot crease, and a short hyperextended hallux. This appearance for these feet may not be apparent until after 1–3 casts. They have been called “complex idiopathic clubfoot” and are more difficult to treat.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- The diagnosis is established clinically.
- Radiographs (after 3 months of age) may confirm bone position but cannot make the diagnosis.
- At 3–6 months of age, anteroposterior and lateral radiograph films in dorsiflexion (maximal correction) may help in defining residual deformity. The beam should be focused on the hindfoot for both the anteroposterior and lateral radiographs as the measured angles will be hindfoot angles.
- Decreased talocalcaneal angle on the anteroposterior and lateral views

(≤ 25 degrees) confirm persistent deformity.

- Medial displacement of the cuboid on the calcaneus and persistent plantar flexion of the forefoot on the hindfoot (talar to 1st metatarsal angle) indicate more complex deformities.

DIFFERENTIAL DIAGNOSIS

Distinguish other deformities of the foot:

- Metatarsus adductus or varus (heel is in neutral position, no fixed equinus)
- Calcaneovalgus (foot is in valgus, no fixed heel equinus)
- Vertical talus (foot is in valgus, heel in equinovalgus)
- Many children with clubfoot also have tibial torsion, which is a normal variant that rarely requires treatment.

TREATMENT

ADDITIONAL TREATMENT

General Measures

- Ponseti method (casting and bracing) and its variations have become the standard of initial treatment.
- Initial treatment:
 - Care can begin in the 1st week after birth, although later treatment is generally successful as well.
- Initial treatment is serial (weekly) manipulation and casting with long leg casts first correcting abduction, then rotation, then dorsiflexion. The talar head is stabilized with the casting physician's thumb while the contralateral hand manipulates the foot.
- Taping may be useful for treatment of the infant requiring ICU care; access to the feet should be maintained for blood tests.
- Surgical intervention should be done if manipulation cannot correct the deformity completely within 8–12 weeks of casting.
- Long leg serial casting by the Ponseti technique improves results so that in most clubfeet, little more than heel cord lengthening and possibly posterior ankle release is required. The operated foot is stabilized for healing for 1 month in a Ponseti-type cast.

- Following surgery, bracing with bars and shoes for 3 months full time and then 3 years nights and naps is an integral part of the Ponseti method.
- With the Ponseti method, 30–45% of patients may have various forms of recurrence requiring repeated casting and/or surgical release through maturity.
- Treatment of complex idiopathic clubfoot require up to 5 additional casts to abduct the forefoot at the midfoot, laterally rotating the anterior tuberosity of the calcaneus under the head of the talus. Recurrence of deformity is more common in this type.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Realignment of the deformity is the goal and should be achieved with casting and surgery.
- Most surgeons cast the feet for 1 month postoperatively.
- With the Ponseti method, bars and shoes are recommended full time for 3 months and nights for 3 years to maintain the correction.
- Remember, the cause of the deformity is not corrected. Only the alignment of the bones and lengthening of the soft tissues are corrected.
- Depending on the severity of the deformity, all corrected clubfeet can be expected to demonstrate varying amounts of calf narrowing and weakness, ankle and subtalar stiffness, a difference between the feet of 1–2 shoe sizes, and even a leg length discrepancy, usually <2 cm.
- There also will be decreased ankle and subtalar motion as compared to normal.
- Adolescent children with clubfeet often will get leg cramps and tire easily while doing sports.
 - Recurrence of heel cord tightness is common, especially during periods of rapid growth.
 - Additional heel cord stretching and casting and, infrequently, additional surgery may be needed.

- All true recurrences should lead to further evaluation for neuromuscular or syndromic causes that might have been undiagnosed in the infant.

CODES

ICD10

- Q66.89 Other specified congenital deformities of feet
- Q66.7 Congenital pes cavus
- Q66.0 Congenital talipes equinovarus

FAQ

- Q: How can a rigid clubfoot be distinguished from a positional clubfoot?
- A: During initial evaluation of the child, it is important to assess the amount of flexibility in a clubfoot. This can be most easily done by flexing the hip to 90 degrees, flexing the knee to 90 degrees, and then gently trying to turn the forefoot into a straight position lined up with the thigh. If the foot easily spins around into a normal position, it can

be assumed that this is a flexible or positional clubfoot. If deformity persists, this is a rigid deformity. If possible, the examining physician should palpate the heel to see if the os calcis comes out of its equinus position filling the heel pad. In some children, particularly with a rocker-bottom sole, the heel pad looks as if it is in the correct position, but the os calcis remains in equinus with the posterior aspect of the os calcis proximal to the heel pad.

- Q: What percentage of clubfeet are successfully treated by casting?
- A: To some extent, the amount of success depends on how much correction is desired. Occasionally, cast correction will provide a partial correction. Some feet, after casting, can be held in the corrected position, only to spin back to the clubfoot deformity when released. Positional clubfeet are likely to improve with casting in perhaps 98% of cases. Rigid clubfeet are much less likely to be corrected by casting. The success rate with casting alone in the rigid feet is likely to be ~10%. It is important to remember that casting and surgery cannot make the clubfoot normal.
- Q: What will be the permanent disability of a congenital clubfoot deformity?
- A: Although casting and surgical correction of a congenital clubfoot can realign the bones, the surgery does little to correct the underlying neuromuscular problems. As a result, all children with rigid clubfeet are likely to have a leg length inequality (usually <1.5 inches), a smaller foot (usually 1–2 sizes), calf narrowing that cannot be significantly improved with exercise, and joint stiffness (ankle, subtalar, and midfoot). Even children with optimal realignment of the deformity will notice their inability to perform gymnastic activities or running activities requiring normal range of motion of the ankle and foot. Many will complain of the inability to keep up with their peer group during adolescent and young adult sports activities.
- Q: How soon should an infant with congenital clubfoot be referred to an orthopedic surgeon?
- A: Casting begins within the 1st–2nd week of life. Medical and life-threatening conditions should take precedence over the treatment of the clubfoot. Access to the feet for IV or blood studies will interfere with a

casting regimen. Casting should begin as soon as is practical. It may even be possible to begin taping of the foot as an alternative to casting, which will still allow IV access to the feet. Referral to an orthopedic surgeon should, therefore, follow as soon as is practical. Studies have shown that excellent results can be obtained from the Ponseti method even when initiated after the 1st year of life.

COARCTATION OF AORTA

Luz Natal-Hernandez

BASICS

DESCRIPTION

- Discrete stenosis of the upper thoracic aorta, usually just opposite the site of insertion of the ductus arteriosus (juxtaductal). A segment of tubular hypoplasia and/or a remnant of ductal tissue give rise to a prominent posterior infolding (“the posterior shelf”).
- The hemodynamic lesion is most often discrete but may be a long segment or tortuous in nature. It is usually juxtaductal but may occur in other sites (i.e., the abdominal aorta). The prevalence of other associations (bicuspid aortic valve) and long-term complications (hypertension) indicate that this lesion may be part of a broader spectrum arteriopathy and/or endothelial disorder.

EPIDEMIOLOGY

Prevalence

- ~6–8% of patients with congenital heart disease have coarctation.
- Male > female (1.5–4.0:1)

RISK FACTORS

Genetics

- Multifactorial: occurs in 35% of patients with Turner syndrome (XO)
- Has been described in cases of monozygotic twins
- Many studies document the prevalence of a microdeletion at 22q11 in patients with arch anomalies and ventricular septal defects.

PATHOPHYSIOLOGY

- Decreased systemic blood flow to lower body after ductal closure
- Increased afterload to left ventricle (LV) causes LV hypertrophy. Relative underperfusion of the renal vessels, baroreceptors, and multiple other mechanisms combine to induce compensatory hypertension.

- If the coarctation is severe, LV dysfunction and congestive heart failure (CHF) result, with low cardiac output and increased LV end-diastolic pressure.
- Decreased myocardial perfusion may be present in cases of very low output.

DIAGNOSIS

HISTORY

There are 2 typical patterns for the clinical presentation of coarctation:

- An infant with CHF or shock: Typically precipitated by ductal closure, this presentation is more common in infants with coarctation and other intracardiac malformations (20–30%):
 - Respiratory distress (dyspnea/tachypnea)
 - Poor feeding
 - Pallor
 - Diaphoresis
 - Poor weight gain
 - Oliguria
- An otherwise asymptomatic child or adolescent with systolic hypertension and/or a heart murmur (70–80%)
 - Lower extremity claudication
 - Headaches

PHYSICAL EXAM

- Tachypnea and tachycardia
- Discrepant arterial pulses and systolic blood pressure (BP) in the upper and lower extremities
- Weak, “thready” pulses
- Grade 2–3/6 systolic ejection murmur
- Gallop rhythm in an infant with CHF
- Ejection click of a bicuspid aortic valve
- The most important finding is decreased or absent lower extremity pulses. Are pulses present? Is there a delay between the brachial and femoral pulses?

- Heart murmur: best heard at the upper left sternal border, at the base, and radiating to the left interscapular area posteriorly
- An infant with severe coarctation and a patent ductus arteriosus (PDA) may have “differential cyanosis.” The lower part of the body appears cyanotic because the descending aortic flow is provided by the right ventricle (RV) through the PDA (check postductal saturation).

ALERT

- The most reliable clinical findings to diagnose native, residual, or recurrent coarctation are the presence of pressure differences in the upper and lower extremities and decreased or absent femoral pulses. Palpable pulses do not exclude coarctation. What one palpates is pulse pressure, not absolute systolic pressure.
- 4-extremity BP measurement is very important in assessing infants and children with possible congenital heart disease. Proper cuff size must be used.
- Bowel ischemia can be present in the ill patient, and emesis or poor feeding are hallmark signs.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Electrocardiogram: RV hypertrophy is usually present in symptomatic infants. The electrocardiogram is often normal in children. LV hypertrophy is apparent with more severe coarctation or longer standing coarctation, particularly in older children.
- Blood tests: In the patient presenting in extremis, management, initial therapy, and timing of surgery can be guided by arterial blood gas analyses and markers of end organ dysfunction.

Imaging

- Chest x-ray: in the infant, moderate to severe cardiomegaly with increased pulmonary vascular markings (PVMs). In an asymptomatic child, the heart size is often normal, with normal PVMs. Rib notching may be seen in older children secondary to dilated intercostal collateral vessels.
- Echocardiography: localization, degree of coarctation, and associated findings (PDA, arch hypoplasia, other defects); assessment of

associated left-sided obstruction: mitral valve abnormality, LV outflow obstruction, and aortic stenosis (bicuspid aortic valve)

- Magnetic resonance imaging: clearly defines the location and severity of coarctation; useful for serial postoperative follow-up (especially aortic aneurysms)

Diagnostic Procedures/Other

Cardiac catheterization and angiography: usually not indicated unless there are further questions to be answered and/or a planned intervention

DIFFERENTIAL DIAGNOSIS

- Other left-sided heart obstructive lesions
- Hypoplastic left heart syndrome
- Cardiomyopathy and/or myocarditis
- Critical aortic stenosis (aortic obstruction to a degree that adequate systemic perfusion depends on patency of the ductus arteriosus)
- Sustained tachyarrhythmia
- Shock from sepsis, metabolic disease, or other entities

TREATMENT

GENERAL MEASURES

- For the sick neonate who presents with severe CHF or shock (ductal-dependent systemic blood flow):
 - Alprostadil (PGE1) prostaglandin infusion: 0.05–0.1 mcg/kg/min (anticipating adverse effects, including apnea)
 - Inotropic support: Dopamine 3–5 mcg/kg/min
 - Diuretics for pulmonary venous hypertension or pulmonary edema
 - Surgical intervention should follow as soon as possible.
- For the asymptomatic child, elective repair and assessment for systemic hypertension are appropriate; however, aggressive antihypertensive pharmacotherapy is not indicated prior to surgical intervention.
- Other
 - Interventional cardiology
 - Percutaneous balloon angioplasty of native coarctation in infants

and children is pursued in some centers. Others have concern about rates of recurrent stenosis, hypertension, aneurysm formation, and iliofemoral arterial injury.

- ▢ Use of vascular stents to relieve the area of stenosis, particularly in older children and adolescents, has provided an alternative to surgical intervention; may increase the need for reintervention in the future when compared to the surgical approach

SURGERY/OTHER PROCEDURES

- Infancy
 - Surgical repair of severe coarctation and coarctation associated with intracardiac anomalies
 - The surgical mortality rate for infants with coarctation and a large ventricular septal defect ranges from 5 to 15% and is higher for children with more complex intracardiac anomalies.
- Childhood
 - Elective coarctation repair between ages 18 months and 3 years in asymptomatic children without severe upper extremity hypertension. Later repair is associated with an increased risk of sustained hypertension and other late complications.
- Types of surgical repair: end-to-end anastomosis, subclavian flap aortoplasty, prosthetic patch aortoplasty, bypass graft

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Reexamine every 12 months with 4-extremity pulse and BP assessment.
- Residual or recurrent coarctation occurs most commonly in those patients requiring repair in early infancy and can depend on the method of intervention (e.g., higher incidence with patch aortoplasty and coarctation ridge resection); most centers delay percutaneous balloon angioplasty of residual or recurrent lesions until 2 months postoperatively.

- Persistent systemic hypertension: most common in patients whose coarctation repair is delayed beyond late childhood
- Aortic aneurysm formation
- Intracranial aneurysms and/or cerebrovascular accidents
- May have hypertension with exercise, even if normotensive at rest
- Exercise-induced hypertension without anatomic stenosis may respond to beta-blocker therapy.

PROGNOSIS

- Untreated coarctation has a poor natural history with the onset of CHF, especially in those patients with other intracardiac malformations. Claudication is common in older children with previously undiscovered coarctation. Generally, the short-term prognosis following successful intervention for isolated coarctation in infancy or childhood is excellent. Procedure-related mortality in every modern series is very near zero.
- Clinical conditions that may affect long-term prognosis after repair of coarctation include the following:
 - Residual or recurrent coarctation
 - Hypertension (rest and exercise)
 - Aortic aneurysm (associated with repair technique)
 - Associated intracardiac lesions
 - Intracranial aneurysms
 - Occurrence or progression of aortic valve disease
 - Premature coronary arterial and cerebrovascular disease
- Associated lesions
 - Bicuspid aortic valve
 - Ventricular septal defect
 - Valvar or subvalvar aortic stenosis
 - Mitral stenosis: often associated with structural mitral valve abnormalities (i.e., supralvalvar mitral ring, thickening of mitral leaflet, single papillary muscle with parachute deformity, or short dysplastic chordae tendineae)
 - Shone syndrome: multiple left-sided obstructive lesions, including supralvalvar mitral ring, parachute mitral valve, subaortic obstruction, and coarctation

- Berry aneurysm of the circle of Willis
- Renal artery stenosis associated with abdominal coarctation
- Congenital diaphragmatic hernia

COMPLICATIONS

- Shock, if severe untreated obstruction
- CHF, if severe untreated obstruction
- Systemic hypertension, before and after intervention
- Intracranial aneurysms
- Mesenteric ischemia
- Paraplegia
- Postoperative complications
 - Bleeding
 - Postcoarctectomy syndrome/mesenteric ischemia
 - Paradoxical hypertension
 - Spinal cord ischemia (0.4%)
 - Residual coarctation
 - Chylothorax
 - Stridor
 - Diaphragm paralysis
 - Aortic aneurysm or dissection
 - Paralysis

CODES

ICD10

Q25.1 Coarctation of aorta

FAQ

- Q: When is the most appropriate time to perform surgical repair of simple coarctation?
- A: Recommendations vary regarding the age at which asymptomatic children (without severe upper extremity hypertension) should undergo intervention. Advances in technique no longer require patients to be “grown” to a threshold size or weight, and there is increasing evidence that severity and incidence of late complications correlate directly with older age at repair. Although some authors mention 3–5 years of age, others recommend repair as early as 18 months to 2 years of age.
- Q: What is the incidence of systemic hypertension after surgical repair of coarctation?
- A: Greatly depends on age at repair, surgical method or technique, length of follow-up interval, and how one defines or measures hypertension. In no situation is the answer zero, and this important complication is one of several reasons patients require lifelong detailed follow-up. 1 year after a technically perfect repair via resection with end-to-end anastomosis, the patient operated on in early childhood is unlikely to have hypertension at rest. However, 20 years further along, a patient of older age at repair is quite likely to have significant hypertension on exercise stress testing.

COCCIDIOIDOMYCOSIS

Camille Sabella

BASICS

DESCRIPTION

Coccidioidomycosis is an endemic systemic mycosis resulting in both asymptomatic and life-threatening disseminated infections.

EPIDEMIOLOGY

- *Coccidioides* spp. are dimorphic fungi that live in the soil.
- Endemic to the southwestern United States (southern California, Arizona, western and southern Texas, New Mexico), northern Mexico, and parts of South and Central America
- Infection is acquired from exposure to aerosolized spores (arthroconidia) usually during recreational or occupational activities; clusters of cases may involve dust storms and earthquakes.
- The average incubation period is 10–16 days (range 1–4 weeks).
- There is no person-to-person spread.
- 60% of acute infections are subclinical (asymptomatic).

Incidence

- 25,000–150,000 new infections per year in the United States
- Highest rate of infection in the summer and early fall

Prevalence

Seropositivity rates in children living in endemic area for 1 year approach 20%, whereas rates in children living in endemic area for 10 or more years approach 80%.

RISK FACTORS

- The course of illness is highly variable and depend on host immune response and amount of exposure.
- Risk factors for disseminated infection:
 - Immunosuppression (especially organ transplant recipients, those receiving immunosuppressive therapies and immunomodulators,

- and those with HIV infection)
- Male gender (adult)
- Neonates, infants, and the elderly
- Filipino, African American, Native American, Hispanic ethnicity
- Pregnancy
- Risk of dissemination is less in children than in adults.

GENERAL PREVENTION

Infection control

- No special isolation or precautions for the hospitalized patient
- Contaminated dressings from skin lesions should be handled and discarded with care.
- Inhalation of aerosolized spores from culture can be hazardous to laboratory personnel.
- Preventive efforts are aimed at dust control and trials to eliminate organisms from soil.
- Immunocompromised people should be counseled to avoid activities that may expose them to aerosolized spores in endemic areas.

PATHOPHYSIOLOGY

- Spores (arthroconidia) are the infectious forms of *Coccidioides* organisms; they are released from the mold and propagate the mold in the soil.
- Inhalation of arthroconidia from disturbed, arid soil is the major route of infection.
- In tissues, arthroconidia enlarge to form spherules. Mature spherules release endospores that propagate in the host and continue the tissue cycle.
- Primary infection occurs in the lungs.
- Most patients have infection limited to a localized area of lung and hilar lymph nodes after mounting an intense inflammatory response with granuloma formation.
- Extrapulmonary dissemination occurs via lymphatic or hematologic spread and usually involves the skin, bones and joints, and central nervous system but can spread to virtually any organ system.

ETIOLOGY

- *Coccidioides immitis* and *Coccidioides posadasii* are the etiologic agents of coccidioidomycosis.
- Asymptomatic infection is the most common outcome, occurring in 60% of infected individuals.
- Primary pulmonary infection accounts for most symptomatic cases; nonspecific illness most common feature (cough, malaise, chest pain, fever); self-limited in most cases; may be accompanied by reactive rashes such as erythema multiforme or erythema nodosum
- Disseminated disease occurs in less than 1% of infected individuals and may manifest with
 - Osteomyelitis: subacute or chronic and frequently involves more than 1 bone (40%). Common sites are the hands, feet, ribs, skull, and vertebrae.
 - Meningitis: develops within 6 months of initial infection. Hydrocephalus is a common complication. Central nervous system vasculitis and intracerebral abscesses are rare.
 - Cutaneous disease: Papules or pustular lesions that ulcerate are most common; most commonly seen on the face but can occur anywhere; regional adenitis is common.

DIAGNOSIS

HISTORY

- Travel or residence in an endemic area is typical. Risk factors for disseminated infection should be sought.
- Acute pneumonia
 - Fever, dry or productive cough, and pleuritic chest pain; hemoptysis is rare in children.
 - Systemic symptoms include headache, malaise, arthralgias, sore throat, and fatigue; rash may be reported.
 - Also known as “valley fever”
- Myalgias, arthralgias, chills, night sweats, and anorexia suggest systemic dissemination.
- Headache, vomiting, and altered mental status suggest meningitis.
- Most infections (60%) are asymptomatic.

PHYSICAL EXAM

- Signs of pneumonia and pleural effusions are often present with symptomatic pulmonary infection.
- Reactive rashes
 - Contain no live organisms
 - Erythematous maculopapular rash and erythema multiforme are seen in 50% of symptomatic children.
 - Erythema nodosum and fever may occur following the onset of symptoms and correlate with the development of cell-mediated immunity (hypersensitivity reactions).
 - Hypersensitivity reactions may occur in the absence of pulmonary symptoms.
- Hematogenous dissemination to the skin
 - Lesions may consist of papules, nodules, abscesses, pustules, sinus tracts, and verrucous ulcers.
 - May be single or multiple
 - Can occur anywhere but are most common on the nasolabial folds
- Stridor is present with infection of the subglottic tissues.
- Signs of increased intracranial pressure are often seen with central nervous system infection. Classic signs of meningeal irritation and fever may be absent.

ALERT

- Clinicians in endemic areas should maintain a high level of clinical suspicion of primary as well as disseminated infection.
- Diagnosis in nonendemic areas may be missed owing to low clinical suspicion or missed travel history.
- False-negative serologic results may occur during the initial weeks of infection or in an immunocompromised host.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Direct examination and culture
 - Cytologic examination of bronchoalveolar fluid is diagnostic in only about 1/3 of persons and is less sensitive than culture. Visualization of large spherules is possible in stained specimens of sputum,

tracheal aspirates, urine, or tissue biopsy. They are rarely seen in CSF.

- The organisms can be detected by culture in experienced laboratories. The yield is highest from purulent material. The yield from other sources, such as pleural fluid, blood, and gastric aspirates, is lower.
- A DNA probe can identify *Coccidioides* species in cultures.
- Coccidioidin or spherulin skin intradermal testing has been used as an epidemiologic tool in the past but is no longer commercially available.
- Serologic studies
 - Serve as valuable diagnostic and prognostic tools but may be hampered by false-negative results early in the course of infection and in immunocompromised hosts; false-positive reactions occur as a result of cross-reactivity with other endemic mycoses.
 - *C. immitis*–specific IgM antibody is detectable in 75% of patients 1–3 weeks after symptom onset and usually is absent after 6 months. False-positive results are seen in 15% of patients with cystic fibrosis.
 - IgG is detected by the complement fixation (CF) assay from serum or CSF. It is positive in 50% of patients at 4 weeks and 83% at 3 months following symptomatic primary infection. In general, higher titers reflect more extensive infection, and rising CF antibody concentrations are associated with worsening disease.
 - Enzyme immunoassay (EIA) for qualitative detection of IgM and IgG is sensitive but can yield false-positive results. It can be useful for screening, but a positive EIA should be confirmed with another test.
 - Hematologic findings include elevated erythrocyte sedimentation rate, leukocytosis, and eosinophilia (in 10%).
- Other studies
 - CSF findings in meningitis include hypoglycorrhachia and pleocytosis with mononuclear cell predominance.

Imaging

Radiologic studies

- Chest radiograph may reveal well-circumscribed nodules, lobar or

patchy pulmonary infiltrates, pleural effusions, cavitary lesions, and hilar adenopathy.

- Radiographs of involved bones may reveal lytic lesions. Scintigraphy or MRI of bone is more sensitive for the diagnosis of osteomyelitis.

DIFFERENTIAL DIAGNOSIS

- Other pulmonary mycoses (e.g., *Histoplasma capsulatum*, *Aspergillus fumigatus*, and *Blastomyces dermatitidis*)
- *Mycobacterium tuberculosis* (lung or CSF)
- *Mycoplasma pneumoniae*
- Influenza and other viral infections that present as bronchopneumonia
- Skin lesions may mimic other endemic mycoses, tuberculosis, actinomycetes, or syphilis.

TREATMENT

MEDICATION

- Uncomplicated or minor disease is self-limited and should not be treated with antifungal therapy (>95% of cases).
- Treatment of uncomplicated respiratory infection is recommended for infants, pregnant women, and patients with continuous fever for >1 month, >10% weight loss, extensive or progressive pulmonary disease, or immunodeficiency (either from HIV or as a result of immunosuppressive medications). Use either oral fluconazole or itraconazole for 3–6 months.
- Diffuse pneumonia or immunocompromised host: Start therapy with amphotericin B and replace with oral fluconazole or itraconazole when clinical improvement is demonstrated. The total length of therapy should be at least 1 year, and for patients with severe immunodeficiency, oral azole therapy should be continued as secondary prophylaxis.
- Disseminated infection, nonmeningeal: Treat with oral fluconazole or itraconazole. Amphotericin B may be used initially, especially for patients with severe or rapid progression of disease. The duration of therapy may be longer than for those with pneumonia only.

- Meningitis: Oral fluconazole is preferred (12 mg/kg/24 h once daily or divided b.i.d., max 800–1,000 mg/24 h). Itraconazole (10–20 mg/kg/24 h divided b.i.d.–t.i.d., max 600 mg/24 h) for 3 days, 4–10 mg/kg/24 h divided b.i.d. (max 400 mg/24 h) thereafter, is an alternative agent. Therapy should be continued indefinitely.
- Intrathecal amphotericin B may be useful in central nervous system infections for those who fail to respond to azole therapy.
- Surgical debridement is used for localized and persistent lesions in bone and lung.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Patients with mild primary respiratory tract infections who are not treated with antifungal therapy should be assessed at 3–6 months intervals for up to 2 years to ensure that their clinical and radiographic findings have resolved.
- Periodic assessment should be done for all patients treated with antifungal therapy throughout their treatment and after cessation of antifungal therapy.
- Patients who are being treated for meningeal infections should undergo CSF assessment every 3 months for life.
- Rising or unchanging CF titers while the patient is receiving treatment may indicate treatment failure, most often due to noncompliance or an occult focus that may require surgical drainage.
- All azoles inhibit P450 enzymes. Consider drug–drug interactions when the patient is taking other medications.

PROGNOSIS

- Most infections are asymptomatic (60%) or mild (35%) and self-limited.
- Primary infection of the lungs is usually self-limited, with a course of illness lasting 1–3 weeks; complications (see below) may prolong the course.

- Fatigue can last for several months.
- Dissemination is infrequent (see earlier section for risk factors).
Morbidity and mortality have improved with use of antifungal therapy, but immunocompromised patients still have a poor prognosis after the development of disseminated infection. The mortality rate is 70% in HIV-infected patients with diffuse pulmonary coccidioidomycosis.
- Meningitis, untreated, is nearly always fatal within 2 years of diagnosis.

COMPLICATIONS

- Localized complications of primary pulmonary infection are infrequent and include pleural effusions and pericarditis.
- ~5% of lung infections result in residual pulmonary sequelae, usually nodules or abscess cavities. 1/3 of these cavities spontaneously resolve within 2 years. Hemoptysis and rupture of the abscess, with formation of an empyema, are potential complications in patients with unresolved cavities.
- Extrapulmonary dissemination usually develops within a year after the initial infection but may appear much later if immunity is impaired (e.g., HIV infection, malignancy, immunosuppressive or immunomodulatory therapy).
- Hospital admission seems to be more common in patients with comorbid conditions and frequently necessitates surgical intervention.
- Hydrocephalus may occur with central nervous system involvement.

CODES

ICD10

- B38.9 Coccidioidomycosis, unspecified
- B38.2 Pulmonary coccidioidomycosis, unspecified
- B38.3 Cutaneous coccidioidomycosis

FAQ

- Q: Do all patients with symptomatic primary respiratory infection due to *C. immitis* require treatment?
- A: No. Because >95% of initial pulmonary infections are self-limited, treatment is not always required. Patients with concurrent risk factors (e.g., HIV, organ transplant, or high doses of corticosteroids) or evidence of unusually severe infections should always be treated. Factors suggesting increased severity of infection include weight loss of >10%, symptoms for 3 or more weeks, infiltrates involving more than half of 1 lung or portions of both lungs, and CF antibody to *C. immitis* >1:16.
- Q: What is the best option for treatment of the child with coccidioidal meningitis?

- A: Fluconazole has become the treatment of choice because of its ease of administration, excellent central nervous system penetration, and safety profile. Other azoles such as ketoconazole and itraconazole appear to also be effective in adults. Intravenously and intrathecally administered amphotericin B is considered a 2nd-line agent because of its inconvenience and adverse effect profile.

COLIC

Cori Green

BASICS

DESCRIPTION

Crying is considered a normal part of human behavior and is a baby's most effective form of communication. However, when crying is perceived to be in excess than what is expected, it can cause a family a great deal of distress. Colic is a syndrome of excessive crying for which no organic cause can be identified. It is described as unexplained end of the day crying that begins at age 2–3 weeks, peaks at 8 weeks, and tapers at 12 weeks.

No standard definition of colic exists. The most widely used definition is from 1954 (Wessel) and referred to as the rule of 3's. He defined colic by the amount of crying: >3 hours a day, >3 days a week, and lasting at least 3 weeks. Colic episodes usually begin suddenly, with no clear reason, and at the end of the day or evening. The crying is intense and high pitched. Infants may have a flushed face, furrowed brow, and postural changes such as bending or drawing up of the knees, clenched fists, and tensed abdominal muscles. Episodes may end with a bowel movement or passing of gas.

EPIDEMIOLOGY

- Crying is one of the most common reasons families present to a health care professional during the 1st months of life.
- 1 in 6 families who have children with colic seek care from a health care professional.
- Estimates are difficult to make due to lack of standard definition; literature suggests a prevalence of 3–40%.
- Incidence is similar in male and females and in breast- and bottle-fed infants.

RISK FACTORS

Possible risk factors include maternal smoking, increased maternal age,

and being the firstborn child. In addition, colic has been associated with higher levels of maternal stress, anxiety, and depression.

GENERAL PREVENTION

Although no study has shown any certain way to prevent colic, educating parents about infant crying can be helpful. Remind parents that crying is an infant's way to communicate, inform them of the expected average hours a day and infant may cry, and teach them soothing techniques.

ETIOLOGY

- The term colic is now considered a misnomer because it derives from the Greek word for colon. Studies in the early 1900s suggested colic was a result of gastrointestinal (GI) dysfunction, whereas today, there are many theories.
- Typically, colic is considered to result from an interaction between infant factors and the environment at a unique time of biologic vulnerability. No single cause has been identified. Several hypotheses for the etiology exist.
 - GI disturbances are often implicated in colic. Abnormal motility has been hypothesized and is somewhat supported by the fact that anticholinergics may improve symptoms. Other studies have shown infants with colic have decreased amounts of lactobacilli and increased amounts of coliform bacteria. Although another theory is that increased gas production can cause colic, this theory is not supported based on radiographs taken during crying spells. Recent studies have suggested an association with *Helicobacter pylori* and infantile colic. Others theorize that colic is a form of milk protein allergy. However, these studies are limited and no causality has been established.
 - Psychosocial issues have been implicated including family tension, parental anxiety, or inadequate parent–infant interactions. However, in studies where infants are cared for by trained occupational therapists, symptoms did not improve.
 - A neurodevelopmental etiology is supported by the fact that infants with colic have similar patterns of crying to infants without colic and that colic is outgrown. Excessive crying has also been

considered a manifestation of normal emotional development where colic is on the end of a spectrum of crying.

DIAGNOSIS

HISTORY

- Obtain details about the infant's behavior around the start of a crying episode and the intensity, time of day, and duration of crying. Documenting this can help both the caregivers and health care providers.
- Prenatal history and history of fever in the infant is important to assess infant's risk of infection.
- History about stooling and vomiting should be elicited to eliminate organic etiologies of crying such as gastroesophageal reflux, malabsorption, or pyloric stenosis.
- History of color changes, apnea, or respiratory distress should help assess for a cardiac or respiratory etiology for crying.

PHYSICAL EXAM

- For the diagnoses of colic, vital signs, growth, and physical exam should be normal.
- Look for signs of trauma or evidence of nonaccidental injuries. Look for bruises and palpate bones to look for fractures. A thorough GI and neurologic exam should also be performed.

DIAGNOSTIC TESTS & INTERPRETATION

No tests are indicated if there are no concerning signs on history or physical.

DIFFERENTIAL DIAGNOSIS

- Normal crying
 - As studied by Brazelton in 1962, at 2 weeks, normal infants cried for a median of 1¾ hour a day, just under 3 hours at 6 weeks, and ~1 hour by 12 weeks. Normal crying, like colic, tends to occur predominantly in the evening and can vary from day to day.
- Organic causes of excessive crying:

- Cardiac: congenital heart disease, supraventricular tachycardia
- Respiratory: upper respiratory infection, pneumonia, foreign body aspiration, pneumothorax
- GI: constipation, cow's milk protein intolerance, gastroesophageal reflux, lactose intolerance, intussusception, rectal fissures, and strangulated inguinal hernias
- Neurologic: hydrocephalus, subdural hematoma, infantile migraine, neonatal drug withdrawal
- Metabolic: hypoglycemia, electrolyte abnormalities, ingestions, inborn errors of metabolism
- Infectious: meningitis, otitis media, urinary tract infections, and viral illnesses
- Trauma: child abuse, corneal abrasions, foreign bodies in the eye, fractures, and hair tourniquets

ALERT

Although organic causes are found in less than 5% of infants who present with crying, it is important to look for red flags in the history and physical such as the following:

- **Symptoms elicited in history:**
 - Vomiting that is frequent, large quantity (>1 oz), bilious, or projectile
 - Bloody stools
 - Poor weight gain
 - Respiratory difficulties including apneic or cyanotic episodes
 - Fever, lethargy, poor feeding
- **Signs observed on physical exam:**
 - Irritability, tachycardia, pallor, mottling, poor perfusion
 - Abnormal neurologic findings including hypotonia, a full fontanelle, or a head circumference >95%
 - Petechiae, bruising, tachypnea, cyanosis, nasal flaring
 - Weight decreasing

TREATMENT

MEDICATION

The literature does not support the use of pharmacologic interventions in colic. Although some studies have shown certain pharmacologic agents to be effective, these studies lack methodologic rigor or involve medications with serious adverse effects.

- Anticholinergic medications such as dicyclomine hydrochloride and cimetropium have been proven to be effective. However, these medications are contraindicated in infants younger than 6 months in the United States due to side effects such as apnea and drowsiness.
- Simethicone is an over-the-counter drug that decreases intraluminal gas. Studies of its efficacy have been mixed and any reduction of symptoms has been attributed to a placebo effect.
- Probiotics may play a role in reducing symptoms. Studies comparing *Lactobacillus reuteri* DSM 17938 to placebo in breastfed infants have shown a reduction of symptoms. These studies are promising; however, further studies confirming these results are needed.

ADDITIONAL TREATMENT

General Measures

The most important and effective treatment is for health care providers to acknowledge the difficulty of the situation and to provide reassurance. Parents of a colicky infant often feel tired and inadequate and need their concerns to be substantiated by a provider who acknowledges how difficult of a time this must be. Main points to reassure and guide parents include the following:

- The crying of colic can be persistent, but there is no evidence of a physical problem or proof that the infant is in pain. Periods of wellness each day followed by periods of crying is reassuring.
- Colic is benign and self-limited; the majority of infants improve by age 3–4 months.
- During crying spells, the infant is probably overaroused and tired.
- On average, a healthy infant will cry 2–3 hours per day.
- Strategies for soothing their infant such as swaddling, making “Shh” sounds, swinging the baby (no more than 1 inch back and forth), pacifier use, repetitive sounds, and decreasing environmental stimulation

- Anticipatory guidance on child abuse prevention (e.g., encouraging parents to take a break when their infant's crying is causing them excessive distress or to turn to each other or others for support)

Diet Modification

- Breastfeeding mothers are encouraged to continue to breastfeed. There is conflicting evidence about whether mothers should eliminate allergenic foods from their diet.
- Although hydrolyzed formulas have been shown to reduce symptoms of colic, most of these studies lack methodologic rigor. In addition, if symptoms do improve, milk protein allergy must be considered.
- Although soy milk formula has been shown to reduce crying, it is not recommended in the treatment of colic due to the prevalence of allergy to soy.
- High-fiber formulas and lactase drops have not been shown to be effective.

Behavioral Modifications

- Car-ride simulators, crib vibrators, and increased carrying have not been shown to be effective.
- Other interventions such as modified parent and infant interactions involving decreased stimulation, “contingent music,” and assisting parents in acquiring effective coping and consoling methods have shown some benefit. However, none of these studies involve randomization and blinding, and most are of small sample size.

COMPLEMENTARY & ALTERNATIVE THERAPIES

- Although teas containing chamomile, vervain, licorice, fennel, and lemon balm have been shown to be effective if used 3 times a day with 150 mL per dose, they are not recommended. Adverse events have been reported. The dose is a large volume. In addition, there is no standard dosing or formulations of these products.
- Sucrose solutions have been found to improve symptoms compared to placebo, yet evidence is limited and there are concerns about nutritional effects and lack of standardization for formulation of preparations.
- Chiropractic care, infant massage, and acupuncture have also been

studied, but due to mixed results and lack of methodologic rigor, they are not recommended in treating colic.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- It is important to keep in close touch with parents of an excessively fussy baby. Telephone contact every 2–3 days is essential until improvement.
- Although reexamination may not be needed, consistent follow-up from a supportive physician may help reassure parents.

DIET

Breast milk and formula changes are not recommended unless milk protein allergy is suspected.

PATIENT EDUCATION

Educate parents regarding the average number of hours an infant is expected to cry and provide soothing techniques. Reassure that colic is benign and self-limited.

PROGNOSIS

- Without intervention, this prolonged crying usually diminishes around 3–4 months of age.
- Some studies suggest infants with colic can have difficulties later in life in family communication, dissatisfaction, and sleeping, psychological, or GI disorders; however, other research has shown no long-term consequences.
- There is no association between colic and later diagnosed asthma or allergic disease.

COMPLICATIONS

Most complications are related to the fatigue, anxiety, and distress that colic can cause in families. The most serious outcome is if parental exasperation leads to the physical abuse of the infant.

CODES

ICD10

- R10.83 Colic
- R68.11 Excessive crying of infant (baby)

FAQ

- Q: What is colic?
- A: Excessive crying in an infant for which no organic etiology is identified. Crying usually is for at least 3 hours a day, for 3 days a week, for a minimum of 3 weeks.
- Q: Why do certain infants get colic?
- A: The etiology of colic is poorly understood. Although there is evidence that GI dysfunction can cause colic, most believe colic is a neurodevelopmental syndrome.
- Q: How is colic treated?
- A: Pharmacologic, nutritional, and behavioral interventions are not recommended. The most important treatment a health care provider can provide is to substantiate a parent’s concern, provide reassurance, educate, and provide anticipatory guidance about colic.

COMA

Jennifer Huffman

BASICS

DESCRIPTION

Coma is defined as a state in which the patient appears to be asleep, shows no awareness of his or her surroundings, and cannot be aroused. Coma frequently is only a transient state, whereby patients recover, die, or progress to a permanent state of impairment. Often a medical emergency, immediate intervention may be required to preserve life and brain function.

- Coma is at the far end of a spectrum of acute impaired consciousness, which also includes the following:
 - Lethargy or stupor: patient arousable but does not stay awake; impaired responses to commands
 - Delirium: a confused, agitated patient with fragmented attention, concentration, and memory
- Coma may progress to
 - Persistent vegetative state: chronic state of unconsciousness with no awareness or cognition, no voluntary responses, and no language abilities; preserved autonomic functions and sleep/wake cycles
 - Brain death: coma, apnea, and lack of cortical and brainstem responses

EPIDEMIOLOGY

Incidence varies by age, season (infection), and ethnicity (inborn errors of metabolism [IEM]).

PATHOPHYSIOLOGY

Dysfunction of the reticular activating system in the brainstem or bilateral cerebral dysfunction causes impaired arousal and consciousness.

ETIOLOGY

Coma etiology can be traumatic or nontraumatic. Infection is a common

cause of nontraumatic coma. Traumatic coma is more likely in older children.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Trauma
 - Epidural/subdural or intracerebral bleeding, cerebral swelling, and/or diffuse axonal injury
- Intoxication
 - Household drug ingestion including barbiturates, opiates, psychotropics, and salicylates; street drugs; alcohol; smoke or carbon monoxide inhalation; ethylene glycol; lead; and others
- Hypoxia/diffuse ischemia
 - Drowning, suffocation/strangulation, cardiac disease, or complications
- Infection
 - Bacterial or viral meningitis, encephalitis, postinfectious encephalomyelitis, toxic or systemic shock, subdural empyema. Pathogens leading to coma include HSV, Mycoplasma pneumoniae, influenza, and Neisseria meningitidis.
- Postinfectious/autoimmune mediated
 - Anti-NMDA receptor encephalitis, acute disseminated encephalitis (ADEM), acute necrotizing encephalitis (ANE), febrile infection–related epilepsy syndrome (FIRES), CNS lupus
- Metabolic disorders
 - Hypoglycemia (salicylate or ethanol intoxication, insulin overdose/hyperinsulinemia), diabetic ketoacidosis (DKA) (neurologic deterioration on initiation of insulin therapy), hyperglycemic nonketotic coma, Reye syndrome, electrolyte abnormalities (Na, K, Ca, Mg), hepatic/uremic encephalopathy, IEM, endocrine abnormalities (hypothyroidism, Addisonian crisis), hypothermia/hyperthermia
- Tumor
 - Can cause increased intracranial pressure and herniation

- Seizure
 - Nonconvulsive status
- Vascular
 - Infarction, hemorrhage from arteriovenous malformation (AVM), aneurysm, coagulopathy, cerebral venous thrombosis, hypertensive encephalopathy, basilar-type migraine
- Hydrocephalus
 - Ventriculoperitoneal (VP) shunt obstruction, mass/bleed obstructing ventricular outflow

Disorders mimicking coma include the following:

- Psychogenic coma
 - Patient may resist passive eye opening, regard self in a mirror, and avoid passive arm fall over face and other noxious stimuli.
- Catatonia
 - A form of psychogenic coma; patients may hold a posture, sit, or stand.
- Locked-in state/complete paralysis
 - Patient is paralyzed with intact cerebral function; may occur in severe neuromuscular disorders or in ventral pontine lesions

HISTORY

- **Question:** Evidence or history of head trauma, drowning, or other trauma?
- Significance: Are there concerns for nonaccidental trauma?
- **Question:** What medications are in the home? Has the patient been depressed or displayed suicidal behaviors? Is there a history of illicit drug use?
- Significance: Ingestion/drugs/toxins
- **Question:** Recent fevers, viral or bacterial illnesses, mental status changes, sick contacts, immunosuppression, infectious risk factors?
- Significance: Infection
- **Question:** Past medical history risk factors?
- Significance: Epilepsy, diabetes, heart disease, neurologic disease including previous episodes of coma, history of failure to thrive (IEM)
- **Question:** Recent nausea, vomiting, mental status change?
- Significance: Increased intracranial pressure

PHYSICAL EXAM

- Vital sign changes: Hyperthermia suggests infection, intoxication, and neuroleptic malignant syndrome. Tachycardia suggests fever, pain, hypovolemia, arrhythmia, and heart failure.

ALERT

Hypertension, bradycardia, and irregular respirations (Cushing reflex) herald impending brain herniation.

- Skin changes: Look for rashes suggesting infection, bruising, and other evidence of trauma; neurocutaneous stigmata may be associated with seizures; feel anterior fontanelle in infants for evidence of increased intracranial pressure (ICP).
- Neurologic exam: Focus on general level of awareness, eye movements, and motor responses to accurately define coma versus lethargy or delirium. Findings can be used in various coma scales.
- Eye movements: Persistent eye deviation is associated with contralateral seizure activity or ipsilateral brain lesions. Impaired upward gaze may indicate high ICP. Nystagmus can be seen in intoxications.
- Pupillary reaction: Small reactive or large reactive pupils suggest intoxication. Anisocoria suggests unilateral brainstem compression. Fixed, dilated pupils indicate global herniation/brain death. Perform oculocephalic (doll's eye) and oculovestibular (calorics) to confirm.
- Motor exam: Assess tone, reflexes, and motor responses to stimuli. Flaccid tone and areflexia are serious signs if not related to medications or lower motor neuron disease. Pressure on the supraorbital notch beneath medial eyebrow will avoid reflex pain responses. Localizing pain entails purposeful movements to remove the stimulus. Withdrawal from pain is less purposeful. Decorticate (adduction with elbow and wrist flexion) and decerebrate (extension, internal rotation of arms) may be provoked by stimulation. They can be asymmetric and intermittent and should not be mistaken for seizures.
- Glasgow Coma Scale/Pediatric Glasgow Coma Scale—associated with prognosis in certain situations (see [Appendix, Tables 5 and 6](#))
 - Eye opening (score range 1–4)

- Verbal response (score range 1–5)
- Motor response (score range 1–6)

DIAGNOSTIC TESTS & INTERPRETATION

Initial blood studies obtained with placement of an IV line include the following:

- Glucose, electrolytes, blood urea nitrogen/creatinine, calcium, magnesium, phosphorous
- CBC and blood culture
- Arterial blood gas
- Toxicology screen (consider EKG)
- Ammonia, liver transaminases, CK

Other helpful studies based on the clinical picture may include the following:

- Metabolic labs (urine organic acids, serum amino acids, lactate), urinalysis, urine culture, thyroid function tests, cortisol, coagulation studies, carboxyhemoglobin (CO poisoning), ANA, anti-NMDA receptor antibodies
- LP (opening pressure, glucose, cell count, protein, Gram stain, culture) to rule out infection or bleed; defer until after CT if focal exam or signs of increased ICP. If question of traumatic tap, spin out red cells promptly and examine fluid for xanthochromia. Simultaneous fingerstick blood glucose is ideal.
- EEG can be helpful to rule out nonconvulsive status epilepticus, especially in patients with a history of seizures or clinically suspected seizures. Continuous EEG may be needed to make this diagnosis.
- Electrophysiologic studies including somatosensory evoked (SEP), brainstem auditory evoked, and visual evoked potentials may be helpful for diagnosis and prognosis.

Imaging

- Head CT: Quick noncontrast scan can detect hemorrhage, hydrocephalus, herniation, and masses; may be followed by contrast images or MRI; should be done prior to LP to rule out a mass (risk for herniation from LP)
- Cervical spine series (CT or lateral and anterior–posterior radiograph

studies): indicated if with evidence of trauma by history or on physical exam. Spine must be stabilized until injury is ruled out.

- Brain MRI: can help with diagnosis and prognosis if prior workup is unrevealing. Consider MRA to evaluate arteries and MRV to rule out venous thrombosis. MRS can help clarify hypoxic and metabolic etiologies.

TREATMENT

SURGERY/OTHER PROCEDURES

Neurosurgical intervention may be required in cases of head trauma, hemorrhage, mass lesion, or hydrocephalus. Neurology consultation is usually indicated.

INPATIENT CONSIDERATIONS

Initial Stabilization

- First priority is airway, breathing, and circulation management.
- If head trauma is suspected, stabilize the cervical spine with a collar while securing the airway.
- Endotracheal intubation: often required for airway protection and adequate oxygenation
- Place large-bore IV lines for isotonic fluids to maintain intravascular volume and blood pressure as needed.
- Evidence of increased ICP
 - Hyperventilate to decrease blood carbon dioxide to 30–35 torr.
 - Consider 3% hypertonic saline (HS) as bolus or continuous infusion, which may be more efficacious than other osmotic agents.
 - Consider mannitol (0.5–1 g/kg IV); can also give dexamethasone 1–2 mg/kg IV
 - Treat fever with antipyretics and environmental cooling methods.
 - Elevate head to 30 degrees above horizontal; avoid head-turned posture to maximize cerebral venous drainage.
 - Hospitalization in the intensive care unit for close monitoring of changes in respiratory status or signs of increased ICP
 - Neurosurgical consultation; consider role for decompression

craniectomy.

- If fingerstick glucose is low, give 2–4 mL/kg of 25% dextrose (D25) IV (D10 for infant).
- If opiate ingestion is suspected, administer naloxone (0.1 mg/kg IV for infants <5 years of age or <20 kg; 2 mg for older, larger children).
- Correct electrolyte and acid–base abnormalities.
- Empiric treatment with IV antibiotics and acyclovir should be started if bacterial or viral meningitis is suspected.
- Consider benzodiazepine (lorazepam 0.05–0.1 mg/kg IV) for suspected seizure activity, although this may compromise neurologic examination.

ONGOING CARE

PROGNOSIS

- Prognosis depends on underlying etiology and patient's clinical course. It is not advised to prognosticate too early.
- Serial exams combined with diagnostic tests (electrophysiology, imaging) will provide more complete information.
- The following portend poor prognosis: absent motor responses to painful stimuli on day 3, no spontaneous eye opening after 1 week, bilaterally absent SEP, and isoelectric baseline or burst suppression on EEG at 1 week.
- Conversely, a reactive EEG is associated with improved outcomes. Some of these findings are more firmly established in adults but, in the right clinical context, may be applicable to pediatric patients.

COMPLICATIONS

- Acute coma
 - Brain injury
 - Respiratory failure/aspiration
 - Seizures
 - Infection
- Chronic sequelae
 - Epilepsy

- New cognitive and/or motor baseline

CODES

ICD10

- R40.20 Unspecified coma
- R40.1 Stupor
- R40.3 Persistent vegetative state

FAQ

- Q: What is the value of the Pediatric Glasgow Coma Scale (PGCS)?
- A: The PGCS is helpful in predicting prognosis but not for diagnosing the cause of coma. The etiology of coma can impact the usefulness of the scale. For example, PGCS has a better correlation with outcomes following traumatic brain injury than for cold water drowning.
- Q: When a bacterial infection is suspected as a potential etiology of coma, should antibiotic therapy be delayed until CSF has been obtained for testing?
- A: Starting antibiotic therapy prior to obtaining CSF may lead to a false-negative CSF culture. However, if there is any concern for increased ICP or mass effect, a CT should be obtained prior to an LP,

and antibiotics should be started in the meantime.

COMMON VARIABLE IMMUNODEFICIENCY

Elena Elizabeth Perez

BASICS

DESCRIPTION

- Common variable immunodeficiency is the most common clinically important primary immunodeficiency syndrome, characterized by
 - Low IgG, IgA, and/or IgM
 - Recurrent infections
 - A wide spectrum of immunologic abnormalities, including autoimmune disease, inflammatory conditions, and the development of lymphomas
- Other terminology for this disease include the following:
 - Acquired hypogammaglobulinemia
 - Adult-onset hypogammaglobulinemia
 - Dysgammaglobulinemia
 - Common variable hypogammaglobulinemia
- Diagnosis of exclusion, requiring low IgG and variable reduction in IgA and/or IgM, impaired specific antibody responses

EPIDEMIOLOGY

- Prevalence is estimated to be 1 in 25,000 to 1 in 66,000 in the general population.
- Can present at any age
 - Most diagnosed between 20 and 40 years old
 - Diagnosis is usually made several years after the onset of recurrent infections (pneumonia, sinusitis, otitis).
- A subgroup of children has been described in which the onset of disease was most often <5 years of age. This group was characterized by a relapsing and remitting course in which autoimmune disease predominated.
- About 20–25% of patients with common variable immunodeficiency have 1 or more autoimmune conditions at time of diagnosis.
- Affects males and females equally

RISK FACTORS

Genetics

- Complex genetics, likely multifactorial
- Rare recessive mutations described in
 - T-cell inducible costimulatory (ICOS) in one kindred, <1% of patients
 - CD19 in a few unrelated families
 - B-cell activating factor (BAFF)
 - CD20 and CD81
 - Transmembrane activator and calcium-modulating cyclophilin ligand interactor (TACI, TNFRSF13B) in 8% of patients, associated with autoimmunity and lymphoid hyperplasia; heterozygous mutation more common than homozygous; significance not clear due to similar mutation found in healthy family members
- IgA deficiency more likely in offspring of parents with common variable immunodeficiency
- Incidence of IgA deficiency, autoimmune disease, and malignancies is increased in family members of patients with common variable immunodeficiency.

PATHOPHYSIOLOGY

- Main characteristic is hypogammaglobulinemia.
- Impaired immunoglobulin and specific antibody production despite normal B cell numbers
- Often increased proportion of immature B cells
- Deficiency of class-switched memory B cells associated with more complex disease (autoimmunity, granulomatous disease, hypersplenism, and lymphoid hyperplasia)
- Functional defects of both B and T lymphocytes are described.

ETIOLOGY

- The primary immunologic defect(s) leading to this syndrome is unknown.
- Multiple defects have been associated with common variable immunodeficiency, including the following:
 - Lack of somatic mutation within variable region genes

- Lack of memory B cells
- Impaired maturation, IL-12 secretion, and upregulation of costimulatory molecules by antigen-presenting cells may impair T cells, which are important for providing help to B cells for antibody production.
- Toll-like receptor 9 (TLR9) response and expression by B cells may also be impaired. TLR signaling pathways are being investigated for their potential role in pathogenesis of common variable immunodeficiency.
- Some genetic defects have been described but do not account for the majority of cases.

DIAGNOSIS

HISTORY

- Recurrent sinopulmonary infections, especially sinusitis and pneumonia, with encapsulated bacteria
- Autoimmune diseases such as autoimmune hemolytic anemia, idiopathic thrombocytopenic purpura, thyroid disease, and chronic active hepatitis
- Localized or systemic granulomatous disease that can be diagnosed years before low IgG is discovered. Lungs, spleen, and lymph nodes are most commonly affected; can be misdiagnosed as sarcoidosis
- Persistent diarrhea of infectious (e.g., *Giardia lamblia*) or noninfectious causes
- Inflammatory bowel disease–like disorder in 6–10% of patients
- Noninfectious, diffuse pulmonary complications described as granulomatous-lymphocytic interstitial lung disease (GLILD) exhibit granulomatous and lymphoproliferative histologic patterns (lymphocytic interstitial pneumonia [LIP], follicular bronchiolitis, and lymphoid hyperplasia).
- Severe or unusual viral infections with herpes simplex, cytomegalovirus, and varicella, such as pneumonitis, hepatitis, or encephalitis. Chronic meningoencephalitis can be seen with enteroviral infection.

PHYSICAL EXAM

- Evaluation should focus on the presence of infection.
- 30% of patients will have lymphadenopathy and/or splenomegaly.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- IgG, IgA, IgM below age-appropriate norms
- CBC with differential: Examine smear for evidence of hemolysis in autoimmune hemolytic anemia.
- Autoimmune antibody screen: antinuclear antibody, autoantibody panel
- Stool culture for bacteria and ova/parasites to evaluate chronic diarrhea
- Isohemagglutinins as well as functional antibody titers to bacterial antigens such as tetanus, diphtheria, and pneumococcus are usually low to absent.
- Spirometry may be helpful in following chronic lung disease.
- Mitogen/antigen stimulation studies will help assess lymphocyte function.
- T- and B-lymphocyte enumeration by flow cytometry
- B-cell phenotyping becoming more available
- Absent B lymphocytes in males suggests X-linked agammaglobulinemia rather than common variable immunodeficiency.
- Appropriate cultures based on site of infection

Imaging

Chest and sinus x-ray studies/CT scans may be warranted for evaluation of bronchiectasis and chronic disease.

Diagnostic Procedures/Other

- GI endoscopy with biopsies for cases of idiopathic persistent diarrhea
- Lymph node biopsy in suspected malignancy

DIFFERENTIAL DIAGNOSIS

- Other primary antibody deficiency disorders: X-linked agammaglobulinemia, transient hypogammaglobulinemia of infancy, and selective antibody deficiency
- Severe malabsorption with protein-losing enteropathy
- HIV infection

- Chronic lung disease: cystic fibrosis, immotile cilia syndrome, and α_1 -antitrypsin deficiency
- Primary autoimmune diseases: immune idiopathic thrombocytopenic purpura, autoimmune hemolytic anemia, systemic lupus erythematosus, thyroiditis

TREATMENT

MEDICATION

First Line

Immunoglobulin replacement therapy

Second Line

Antibiotics as needed for infection may also be used as adjunct to immunoglobulin replacement as prophylaxis.

ADDITIONAL TREATMENT

General Measures

- Monthly IV immunoglobulin replacement
 - Starting dose is usually 400–600 mg/kg/month IV to maintain a trough IgG level of at least 500 mg/dL or FDA-approved formulation(s) for SC administration, given weekly or biweekly following the establishment of intravenous immunoglobulin (IVIG) dosage.
- Appropriate antibiotics for acute infections
- Prophylactic antibiotics may be helpful in chronic/recurrent infections.
- Cautious use of corticosteroids may be necessary in the treatment of GI and autoimmune manifestations.

ISSUES FOR REFERRAL

- Autoimmune manifestations
- GI: chronic abdominal pain or signs of possible lymphoid hyperplasia

INPATIENT CONSIDERATIONS

Nursing

- Supervision during IVIG administration
- Monitor for side effects of therapy.

- Have anaphylaxis medications available.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Close and frequent follow-up is warranted for patients with severe, recurrent symptoms. It may be as frequent as monthly, depending on symptoms.
- Signs and symptoms suggesting malignancy (e.g., persistent adenopathy in absence of infection, significant weight loss, or abdominal mass) should be evaluated expeditiously.
- Abdominal pain may indicate infection or lymphoid hyperplasia.

Patient Monitoring

CBC with differential, ALT, creatinine, IgG level

PATIENT EDUCATION

Several Web sites available to patients and families:

- Immune Deficiency Foundation: <http://primaryimmune.org>
- International Patient Organisation for Primary Immunodeficiencies: www.ipopi.org
- The Jeffrey Modell Foundation: www.jmfworld.org
- National Institute of Allergy and Immunology: www.niaid.nih.gov

PROGNOSIS

- Immunoglobulin replacement therapy, prophylactic antibiotics when necessary, and close follow-up by immunology have greatly improved the overall prognosis.
- The newer challenge with this disease is detection and management of autoimmune and other disease-associated complications.
- Phenotypic classifications based on memory B cell numbers divide patients into two major categories: those that do well with IgG replacement alone and others with more likely autoimmune and granulomatous complications.

COMPLICATIONS

- Autoimmune disease in 20% of common variable immunodeficiency

patients; most common are autoimmune hemolytic anemia and idiopathic thrombocytopenia purpura.

- GI complications include chronic diarrhea, malabsorption, and weight loss. Inflammatory bowel disease and *Helicobacter pylori* infection have also been observed.
- Granulomatous infiltrations may mimic sarcoidosis.
- Lymphoproliferative disease: Overall risk is 8–10%. The most common are lymphomas, usually non-Hodgkin lymphoma, well differentiated, mostly Epstein-Barr virus negative.
- Chronic sinusitis and lung disease with abnormal pulmonary function tests
- Progressive decline in T-lymphocyte function

- D83.0 Com variab immunodef w predom abnlt of B-cell nums & functn
- D83.2 Common variable immunodef w autoantibodies to B- or T-cells

FAQ

- Q: What is the life expectancy of patients with the diagnosis of common variable immunodeficiency?
- A: Because the clinical presentations and symptoms are variable, it is difficult to predict the life expectancy in individual patients. IVIG replacement, in addition to antibiotic therapy, has greatly improved the outlook for these patients. However, despite adequate therapy, a large percentage of patients with common variable immunodeficiency have a progressive decline in immune function. Major morbidity and mortality usually result from the associated complications of malignancy, chronic lung disease, and severe autoimmune disease. In one study, the mortality is estimated at 23–27% over a median follow-up of 7 years (0–25 years). The 20-year survival after diagnosis for males is 64% and for females 67% versus 92% and 94%, respectively, for the general population. Main causes of death include respiratory complications, granulomatous disease of organs, liver disease, malnutrition due to GI pathology, uncontrolled autoimmune

manifestations, and lymphoma.

- Q: Should patients with common variable immunodeficiency receive live viral vaccines?
- A: In general, patients receiving IVIG replacement therapy do not require any vaccinations. Live viral vaccines should be avoided in these patients, especially if they have deteriorating immune function.
- Q: Can common variable immunodeficiency be diagnosed prenatally?
- A: Because there are no clear genetic inheritance patterns, prenatal diagnosis is unavailable.

COMPLEMENT DEFICIENCY

Melanie M. Makhija

BASICS

DESCRIPTION

- Complement is a major component of the innate immune system.
 - Consists of plasma and membrane proteins which mediate 3 pathways of cascading enzyme reactions
 - Pathway activation leads to inflammatory and immune responses.
- Deficiencies can arise in any of the proteins, leading to loss of activity of the deficient protein as well as loss of function of proteins that follow in the cascade.
- Inherited deficiencies of the complement components may predispose individuals to infections and autoimmunity.
- Secondary/acquired deficiencies are much more common than inherited deficiencies and are most often caused by increased consumption by immune complexes.

Clinical manifestations of complement deficiencies

Deficiency

Clinical manifestations

C1q,r,s, C2	Systemic lupus erythematosus (SLE), bacterial infections
C4	SLE, autoimmune disorders
C3	Severe infections with encapsulated bacteria (i.e., <i>Haemophilus influenzae</i>), glomerulonephritis, immune complex disease
Factor H, I	Secondary C3 deficiency, atypical hemolytic uremic syndrome
Properdin	Males with neisserial and sinopulmonary infections
Factor D	Neisserial infections

MBL, MASP	Infections with encapsulated bacteria, SLE, rheumatoid arthritis
C5, 6, 7, 8, 9	Disseminated neisserial infections
DAF, CD59	Paroxysmal nocturnal hemoglobinuria
C1 inhibitor	Hereditary angioedema (HAE)

EPIDEMIOLOGY

- Complement deficiency accounts for approximately 2% of all primary immune deficiencies.
- Homozygous C2 deficiency 1 in 10,000
- Borderline C4 in 1–3% of Caucasian population
- C9 deficiency almost always found in people of Japanese descent
- C6 deficiency more common in African Americans
- Alternative pathway deficiencies (properdin, factor D) are rare.

RISK FACTORS

Genetics

- Properdin deficiency is X-linked.
- Most other complement deficiencies are autosomal recessive.
- C1 inhibitor deficiency is autosomal dominant.
- Heterozygotes are usually phenotypically normal.

PATHOPHYSIOLOGY

- Classic complement pathway is activated when IgM or IgG antibodies bind to antigen.
- Lectin pathway is activated when a lectin such as mannose-binding lectin (MBL) binds to antigen.
- Alternative pathway does not need antibody or lectins to be activated.
- Main goal of all 3 pathways is to deposit C3b fragments on the target antigen to mark the target for immune response.

ETIOLOGY

- Primary complement deficiencies are hereditary.
- Acquired deficiencies: accelerated consumption by immune complexes (most common), decreased hepatic production (less common), or loss through the urine (rare)

DIAGNOSIS

HISTORY

Indications for evaluating complement system:

- Recurrent pyogenic infections in patients with normal white blood cell count and immunoglobulin levels
- Recurrent neisserial infections (meningitis, sepsis, gonococcal arthritis) at any age
- Multiple family members who have had neisserial infections
- SLE, especially familial lupus: Evaluate for C2 deficiency.
- Recurrent angioedema without urticaria: Evaluate for C1 inhibitor deficiency (HAE).

PHYSICAL EXAM

- Depends on which component is deficient
- Assess for signs and symptoms of autoimmunity (i.e., SLE) and also of bacterial infections and sequelae.
- Failure to thrive
- Recurrent angioedema without urticaria for HAE

DIAGNOSTIC TESTS & INTERPRETATION

Diagnostic Procedures/Other

- Initial lab tests
 - Total hemolytic complement (CH50): Screens for homozygous deficiencies in the classical pathway. All 9 components (C1–C9) required for normal CH50
 - Complement activity is thermolabile and reduced quickly at room temperature. Low levels often due to improper specimen handling
 - Complete deficiency of any component gives undetectable CH50 level.
 - Heterozygotes may have normal CH50.
- AH50
 - To assess integrity of alternate pathway
- Individual component testing
 - Based on clinical history
- C4, C1 esterase inhibitor level and function may be used to evaluate for

HAE

DIFFERENTIAL DIAGNOSIS

- Antibody (humoral) deficiency syndromes
- Secondary complement deficiencies

ALERT

- Most common cause of low complement levels is improper specimen handling.
- Secondary deficiency may be caused by consumption of complement components.

TREATMENT

MEDICATION

- There are no specific treatments for most complement deficiencies.
- Aggressive diagnosis and treatment of infections with antibiotics
- HAE prophylaxis and treatment for C1 inhibitor deficiency

ADDITIONAL TREATMENT

General Measures

- Consider prophylactic antibiotics to prevent recurrent infections.
- Vaccination with *Streptococcus pneumoniae* and *Neisseria meningitidis* conjugate vaccines as well as *Haemophilus influenzae* for patients and household contacts
- Can receive other routine vaccines (including live viral vaccines) safely
- Wear medical identification tag identifying condition.
- Plasma infusions impractical over lifetime and risk of development of antibody against missing component

ISSUES FOR REFERRAL

- Should be followed by immunologist
- Monitor for autoimmune disease and refer to rheumatologist for autoimmunity management.
- Genetic counseling for family members

ONGOING CARE

COMPLICATIONS

- Severe infections and sequelae including death
- Immune complex disease
- Autoimmunity

CODES

ICD10

D84.1 Defects in the complement system

FAQ

- Q: When should I evaluate for a complement deficiency?
- A: Any child with recurrent sinopulmonary infections or >1 episode of a neisserial infection.

CONCUSSION

Evelyn Porter • Andrea Marmor

BASICS

DESCRIPTION

- Concussion is a complex pathophysiologic process affecting the brain, induced by traumatic biomechanical forces.
- There is a graded set of clinical symptoms that define concussion, which may or may not involve a loss of consciousness.
- Concussion may be caused either by a direct blow to the head or a blow to the face, neck, or elsewhere on the body with an “impulsive” force transmitted to the head.
- Concussion typically results in the rapid onset of short-lived impairment of neurologic function that resolves spontaneously. In a small percentage of children, postconcussive symptoms may be prolonged.
- Concussion may result in pathologic changes, but the acute clinical symptoms largely reflect a functional rather than structural injury and no abnormality is seen on standard neuroimaging studies.

EPIDEMIOLOGY

- A recent review estimated that up to 3.8 million recreation- and sport-related concussions occur annually in the United States.
- Concussion is underreported.
- Most common sports include football, ice hockey, soccer, wrestling, lacrosse, basketball, baseball, softball, field hockey, and volleyball.
- Although concussion is overall more common in boys, girls have higher rates of concussion than boys in similar sports.
- Risk of injury depends on game, position, prior concussion, and use of helmet.

GENERAL PREVENTION

- Nothing has been shown to prevent concussion.
- Helmet use is essential at reducing the severity of a blow to the head.

- Given that children may have a sense of invulnerability and desire to return to usual activities quickly, preparticipation medical visits should emphasize that reporting concussion immediately is essential and that loss of consciousness is not the only manifestation of concussion.

PATHOPHYSIOLOGY

- The brain is buoyed in the cranium by cerebrospinal fluid that acts as protective insulation. With acceleration–deceleration, the brain continues to experience momentum and strikes against bone. The temporal and frontal lobes are particularly prone to injury because of their location adjacent to irregular parts of the skull.
- Depressed level of consciousness is thought to be the result of rotational stretch injury to the reticular activating system in the dorsal aspect of the brainstem.
- Pathologic changes after concussion include alterations in neuronal depolarization and neurotransmitter release, impaired axonal function, decreased cerebral blood flow, and altered brain autoregulation and glucose metabolism.
- Children may respond to brain trauma differently than adults due to developmental factors such as brain size, brain water content, myelination level, skull and suture geometry and elasticity, and differential skull to body proportions.

DIAGNOSIS

HISTORY

- Detailed history of traumatic event
- Detailed symptom evaluation
- History of prior concussions, including surrounding circumstances
- History of preexisting cognitive or attention problems should be elicited to help guide interpretation of postinjury testing.

SIGNS AND SYMPTOMS

- Standardized, validated instruments for mental status testing are available and can be administered quickly on the sideline (i.e., Sport Concussion Assessment Tool 2 [SCAT-2])

- Postconcussive symptoms may be divided into 4 domains:
 - Somatic: headaches, fatigue, decreased energy, nausea, vision change, tinnitus, dizziness, incoordination, and balance difficulty
 - Emotional/behavioral: irritability, increased emotionality, personality change, depression, or anxiety
 - Cognitive: slowed thinking and response time; impaired concentration, learning, and/or memory; and reduced problem-solving ability
 - Sleep disturbances are common.

PHYSICAL EXAM

- Onsite and acute evaluation should include the usual ABCs and evaluation for potential associated injuries such as cervical spinal injury.
- A detailed neurologic examination should be performed to detect focal signs suggestive of serious neurologic impairment and to allow accurate observation over time.
- Mental status: orientation (person, place, time), concentration (digit span), and memory (anterograde and retrograde)
- Cranial nerves: pupil reactivity, eye movements (particularly smooth pursuit and saccadic movements), visual fields, face movement and sensation, tongue protrusion
- Motor: strength and tone
- Sensory: gross sensory deficits
- Cerebellar: agility, finger-to-nose-to-finger, rapid alternating movements (finger tapping, toe tapping), tandem gait (forward and backward, eyes open and closed)
- Exertion provocative tests: 5 push-ups, 5 sit-ups, 5 knee bends, 40-yard sprint; look for change in symptoms/exam.

DIAGNOSTIC TESTS & INTERPRETATION

Imaging

- Structural lesions are absent on standard CT and MRI in concussion.
- Computed tomography of the head (HCT) is the test of choice in the acute evaluation of suspected intracranial hemorrhage or skull fracture in head trauma.

- Decision rules exist to determine those children at low risk for clinically important brain injury who may not need an HCT.
- There is increased suspicion of intracranial injury in patients with abnormal mental status, non-frontal scalp hematoma, prolonged loss of consciousness, severe injury mechanism, palpable skull fracture, vomiting, and severe headache.
- MRI is the imaging modality of choice in the subacute or chronic evaluation of concussion

Diagnostic Procedures/Other

Neuropsychological testing: Computerized testing is now widely available and baseline testing is being performed by many school athletic departments. Research is still needed regarding the optimum timing of this testing and whether it improves outcome.

TREATMENT

GENERAL MEASURES

- Remove the child from the activity with no return to play if concussion is suspected.
- Monitor the athlete for several hours after the injury to evaluate for any deterioration.
- Consider referral to the emergency department if there is repeated vomiting, severe or worsening headache, seizure, unsteady gait, slurred speech, weakness or numbness in the extremities, unusual behavior, signs of a basilar skull fracture, or a GCS <15.
- There is currently no evidence-based research on the use of any medication in the treatment of the concussed pediatric athlete.

ISSUES FOR REFERRAL

- Neuropsychological evaluation should be considered in children with multiple concussions or when recovery is not progressing as expected. This evaluation can document impairment, identify factors contributing to persisting difficulties, and guide school accommodations or formal intervention.
- If admitted for observation, consults by speech therapy, physical

therapy, and psychiatry should be considered to evaluate for subtle sequelae.

SURGERY/OTHER PROCEDURES

Neurosurgical evaluation or transfer to a trauma center should be considered for symptoms of prolonged unconsciousness, persistent mental status alterations, worsening postconcussive symptoms, abnormalities on neurologic examination, or abnormalities on neuroimaging.

INPATIENT CONSIDERATIONS

Admission Criteria

Consider admission if the child continues to have altered level of consciousness, if focal neurologic signs are present, or if patient remains severely symptomatic.

Nursing

If observation is required, nursing staff must be able to perform neurologic assessments at regular intervals.

Discharge Criteria

- Planning must be individualized depending on severity of symptoms, family support, and presence of associated injuries.
- The child and guardian should receive return to play guidelines focused on avoiding repeat concussions as concussions have a cumulative effect and result in increased vulnerability to future injuries.
- No athlete should return to play while still symptomatic from a concussion. This includes physical, cognitive, or behavioral symptoms. There must be no symptoms or signs at rest or during exertion.
- Activities with a high cognitive demand should be limited while symptomatic, including television, computer, videogames, and texting. School accommodations may be needed.
- Before considering return to play, any medication to reduce symptoms must be stopped and the athlete must be symptom-free off medications.
- Return to play should occur in a gradual fashion while monitoring for symptoms because symptoms may be aggravated with exertion. Consider in sequence light aerobic activity, noncontact sport-related activity, full practice, and then game play.

- Retirement should be considered for any athlete who has sustained 3 concussions in an individual season or has had postconcussive symptoms for more than 3 months, when recovery requires an increasing amount of time, or when concussions occur with less forceful injury.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

If the patient is discharged home for observation, the guardian should have detailed instruction regarding reasons to return to the ED. These include difficulty awakening or staying awake, worsening headache or dizziness, emesis, seizures, blood or clear fluid from the ears or nose, major changes in behavior, or any focal weakness/sensory/vision changes.

PROGNOSIS

- In general, the prognosis is excellent but depends on the severity of the injury.
- The typical adult patient with a concussion will recover to baseline function in 6–12 weeks.
- Athletes and children usually recover in 48 hours. However, children with previous head injury, learning difficulties, or neurologic, psychiatric, or family problems may continue to show significant ongoing problems at 3 months.
- Chronic headaches, persistent difficulty with short- and long-term memory, and episodic confusion are common sequelae of the cumulative damage that occurs with repeated concussive injuries.

COMPLICATIONS

- Postconcussion symptoms such as confusion; altered concentration, memory, and problem solving; irritability; emotional changes; and headaches may take several months to resolve.
- Serious head injury may occur and requires immediate neurosurgical evaluation and neurocritical care. Serial HCT imaging may be

necessary as intracranial lesions, such as contusion or hemorrhages (epidural, subdural, intraparenchymal), can expand. These may occur with or without skull fracture and may occur without an initial loss of consciousness.

CONGENITAL ADRENAL HYPERPLASIA

Erica A. Eugster

BASICS

DESCRIPTION

Congenital adrenal hyperplasia (CAH) refers to a group of autosomal recessive disorders that have in common the deficiency of an enzyme needed for cortisol biosynthesis. The disease exists along a spectrum of severity and is typically subdivided into “classic” (severe) and “nonclassic” (milder) forms.

- There are 5 specific causes of CAH:
 - 21-hydroxylase deficiency
 - 11-hydroxylase deficiency
 - 3 β -hydroxysteroid dehydrogenase deficiency
 - 17 α -hydroxylase deficiency
 - Congenital lipoid hyperplasia (stAR mutation)
- The vast majority of cases of CAH (~95%) are due to 21-hydroxylase (21OHase) deficiency, which will therefore be the focus of this chapter. The 21OHase enzyme is in the glucocorticoid and mineralocorticoid biosynthetic pathways.

EPIDEMIOLOGY

- The incidence of classic CAH is 1:10,000–1:20,000 live births.
 - More common in certain ethnic groups and in remote areas.
 - ~75% of cases are characterized by overt salt wasting due to mineralocorticoid deficiency, whereas the remaining cases are described as simply virilizing.
- The prevalence of non-classic CAH (also called late-onset) is approximately 1:1,000.
 - More common in some ethnicities such as Ashkenazi, Italian, and Yugoslavian and may be as common as 1:50 individuals in these groups.

RISK FACTORS

Genetics

- CAH is caused by mutations in the CYP21A2 gene, which is located on chromosome 6p21.3 and encodes for the 21OHase enzyme. This locus is characterized by many overlapping transcripts and a high rate of recombination.
- Most mutations involve large deletions or arise from the transfer of small sequences of the nearby pseudogene CYP21A1P during meiosis. More than 100 different CYP21A2 mutations are known. Most patients are compound heterozygotes, with the phenotype reflecting the milder mutation. Approximately 1% of mutations are estimated to arise de novo and uniparental disomy has been reported in one case.
- Although genotype–phenotype correlations are generally high, the genetic complexity of CAH renders them sometimes problematic.

PATHOPHYSIOLOGY

- The enzymatic block in cortisol biosynthesis results in diminished negative feedback at the level of the hypothalamus and pituitary gland with a subsequent increase in CRH and ACTH. The buildup of precursors proximal to the block results in increased adrenal androgen production. Variable degrees of mineralocorticoid deficiency cause salt wasting and contribute to the risk of adrenal crisis. The clinical consequences of this process vary according to gender and to the severity of the CAH ([Appendix, Table 13](#)).
- Classic CAH; genetic females
 - Androgen excess during early prenatal life (1st trimester) results in ambiguous genitalia. Typical features include elongation of the urethra, development of a urogenital sinus, and enlargement of the clitoris.
 - Development of the internal reproductive structures is unaffected.
 - If not diagnosed and treated early, progressive virilization occurs postnatally. Girls with salt-wasting CAH are also at risk for an adrenal crisis.
- Classic CAH; genetic males
 - Prenatal androgen exposure has no clinical consequence in infant boys with CAH. However, infant boys with salt-wasting CAH are at risk for an adrenal crisis.

- As with girls, if not diagnosed and treated early, progressive virilization occurs postnatally.
- Non-classic CAH; females
 - The far milder degree of androgen excess in non-classic CAH has no effect during embryologic development but can result in symptoms of hyperandrogenism during childhood, adolescence, or adulthood.
- Non-classic CAH; males
 - Symptoms of androgen excess can occur during childhood, adolescence, or adulthood.

DIAGNOSIS

HISTORY

- Any family history of CAH should be sought as well as any history of exposures and/or maternal virilization during pregnancy. In infants, poor feeding, lethargy, and vomiting are important potential clues to an impending adrenal crisis.
- Children with previously undiagnosed CAH typically present with precocious puberty due to androgen excess. Typical symptoms in classic CAH include adult body odor, acne, pubic and axillary hair, penile enlargement in boys, clitoromegaly in girls, and linear growth acceleration. Symptoms of nonclassic CAH during childhood are usually limited to adult body odor and early pubic/axillary hair.
- Symptoms of CAH in adolescent girls include irregular periods, hirsutism, and acne.

PHYSICAL EXAM

- Classic CAH; genetic females
 - Ambiguous genitalia in infant girls with classic CAH exists along a continuum known as the Prader scale. Prader 1 is a typical female, whereas Prader 5 denotes the most extreme degree of masculinization in which the urethral opening is at the tip of the clitoris and complete labial fusion has occurred. Thus, a male sex assignment is sometimes mistakenly made. This scenario is the

rationale for the admonition “Never circumcise a male infant with bilaterally nonpalpable testes!”

- Most girls with classic CAH are Prader 3 or 4. Significant clitoromegaly will be present along with increased rugation and pigmentation of the labioscrotal structures but no palpable gonads. Posterior labial fusion and a single perineal opening is usually found.
- Physical findings in the setting of salt wasting are nonspecific but would include low weight percentile, poor skin turgor, dry mucous membranes, and vital signs suggesting dehydration.
- Although the vast majority of infant girls with classic CAH are diagnosed in the newborn period, occasional cases are missed. If this occurs, the external genitalia will exhibit the same features as in infancy. Other signs of hyperandrogenism will be present such as pubic hair and extreme tall stature from linear growth acceleration. The presence of a urogenital sinus and posterior labial fusion indicate 1st-trimester androgen excess, whereas androgen exposure after this critical period results in clitoromegaly only.
- Classic CAH; genetic males
 - Although average penile size in newborn boys with classic CAH is increased, the external genitalia appear normal and thus there is nothing on physical exam to alert providers to the presence of CAH. As is the case in girls, physical exam findings associated with salt wasting include low weight percentile, poor skin turgor, dry mucous membranes, and vital signs indicating dehydration.
 - Boys with classic CAH who are missed in infancy come to medical attention due to early secondary sexual development. On physical exam, tall stature, adult body odor, acne, pubic and axillary hair, and penile enlargement are seen. A hallmark of CAH and other forms of peripheral precocious puberty in boys is a prepubertal testicular volume, indicating a source of sex steroids other than the HPG axis.
- Nonclassic CAH; females
 - Girls with nonclassic CAH have pubic and/or axillary hair, adult body odor, and \pm acne. Adolescent girls typically have hirsutism. Mild clitoromegaly may also be seen.

- Nonclassic CAH; males
 - Boys with nonclassic CAH will also have signs of mild androgen excess on physical exam including pubic and axillary hair, adult body odor, and acne.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- CAH is included on the newborn screen in all 50 states. The biochemical hallmark is an elevated 17-hydroxyprogesterone (17OHP). Depending on the 17OHP concentration, a repeat newborn screen or a serum concentration is obtained. In any presumptive positive case, serum electrolytes need to be monitored closely for early detection of an adrenal crisis. False positives are extremely common in preterm and sick neonates. An elevated plasma renin will confirm overt salt wasting.
- Any report of an abnormal newborn screen for CAH, particularly in a term infant male, should be considered an emergency.
- Serum 17OHP is also the diagnostic test for classic CAH that was missed in the newborn period and for nonclassic CAH. Testosterone, dehydroepiandrosterone-sulfate (DHEAS), and androstenedione should also be measured.

Imaging

- In infants with ambiguous genitalia, a pelvic ultrasound and genitogram are often performed. In girls with CAH, a normal uterus is seen on ultrasound, whereas a urogenital sinus, “male-type” urethra, and cervical impression are typical findings on genitogram. No routine imaging is performed in infant boys with CAH. However, periodic testicular ultrasound to detect adrenal rest tumors is recommended starting in adolescence, particularly in boys whose CAH is poorly controlled as evidenced by chronic elevations in 17OHP concentrations.
- A bone age x-ray is an important part of the evaluation in children with precocious puberty. In the setting of undiagnosed classic CAH, skeletal maturation will be markedly advanced.

Diagnostic Procedures/Other

- In equivocal cases, a full ACTH stimulation test can distinguish between classic and nonclassic CAH, affected individuals and heterozygous carriers, and between 21OHase deficiency and other forms of CAH.
- Genotyping can also confirm the diagnosis and is helpful for genetic counseling. However, complete sequencing (rather than targeted mutation analysis) of the CYP21A2 gene may be necessary to accurately determine genotype because complex genetic variations are often present.

DIFFERENTIAL DIAGNOSIS

- CAH is the most common 46,XX disorder of sex development. Other causes for ambiguous genitalia are outlined in other chapters.
- The differential diagnosis of classic CAH presenting during childhood includes etiologies of androgen excess such as an androgen-secreting tumor or exogenous exposures. In boys, a β -hCG-producing tumor, McCune-Albright syndrome, and familial male precocious puberty should be considered.
- Nonclassic CAH presenting during childhood is often indistinguishable from premature adrenarche. In adolescent girls, the differential diagnosis includes PCOS, which also shares many clinical features with nonclassic CAH.

TREATMENT

MEDICATION

- Medical treatment of CAH consists of glucocorticoid therapy in doses sufficient to suppress adrenal androgen overproduction, which are generally considered to be 10–15 mg/m²/24 h hydrocortisone equivalent.
- Regardless of salt-wasting status, current recommendations also endorse mineralocorticoid therapy in all patients with classic CAH in the form of Florinef 0.05–0.2 mg/24 h.
- Salt supplementation (NaCl 3–5 mEq/kg/24 h) is also needed during infancy.

ADDITIONAL TREATMENT

Girls with CAH usually undergo genital surgery in the form of a feminizing genitoplasty. However, whether and when such surgery should be performed is controversial.

General Measures

ALERT

Stress-dose glucocorticoid coverage during illness or injury is essential in patients with CAH.

ONGOING CARE

Ongoing clinic visits and monitoring of growth, puberty, and hormonal studies (including serial measurements of 17OHP) are standard of care. Psychological support and educational materials should be provided on a regular basis.

PROGNOSIS

- Adult height is normal when CAH is well controlled but is compromised in poorly controlled or late-diagnosed cases.
- Girls with classic CAH may exhibit boy-typical behaviors but have normal female gender identity.
- Fertility is decreased in women with classic CAH compared to the general population.
- Fertility may be impaired in men with CAH if testicular adrenal rest tumors are present.
- Transition to adulthood ideally takes place in the context of a multidisciplinary team.

FAQ

- Q: When does a salt-wasting crisis usually occur in newborns with CAH?
- A: The most common time is between days 5 and 10 of life. However, it may occur as early as on day 1 of life or not until many weeks or months later.
- Q: When should children with CAH be given a “stress dose” and what does this consist of?
- A: Double or triple the usual glucocorticoid dose is considered a stress dose. This should be given at times of illness or psychological stress. However, if a child is vomiting, an emergency Solu-Cortef injection should be given. Hydrocortisone 100 mg/m² IV is given prior to any surgery.
- Q: What is the best form of glucocorticoid treatment in children with CAH?
- A: Hydrocortisone has long been considered the optimal glucocorticoid in CAH. However, this is controversial, and some patients do well on

prednisone or dexamethasone.

- Q: Should extremely virilized girls with CAH be sex-assigned male?
- A: Because fertility and gender identity are normal in girls with CAH, the current consensus is to raise these girls female regardless of the extent of virilization.

CONGENITAL HEPATIC FIBROSIS

Mansi D. Amin • Eric H. Chiou • Kristin L. Van Buren

BASICS

DESCRIPTION

- Congenital hepatic fibrosis (CHF) is an inherited, noncirrhotic liver disease.
- Prominent clinical features include the following:
 - Portal hypertension
 - Increased risk of ascending cholangitis
- Liver biopsy shows the classic lesion of ductal plate malformation.
- Majority of patients with CHF have associated autosomal recessive polycystic kidney disease (ARPKD). However, several other genetic diseases also result in CHF.

EPIDEMIOLOGY

- The incidence of ARPKD is 1/20,000–1/40,000 live births.
- Carrier frequency of PKHD1 mutation in the general population is ~1:70.

RISK FACTORS

Genetics

- Inheritance is autosomal recessive in most families, but X-linked and autosomal dominant patterns are also seen.
- Penetrance is 100% but marked intrafamilial variation in severity is observed.
- PKHD1, the ARPKD/CHF disease gene, is located on chromosome 6p12.
 - The gene is large, consisting of at least 86 exons extending over 469 kb of genomic DNA.
 - It is expressed at high levels in fetal and adult kidneys and at lower levels in the liver and pancreas.
- More than 300 mutations of the PKHD1 gene have been reported with variable rates of progression of hepatic/renal disease, even with the

same PKHD1 mutation, indicating the presence of modifier genes.

- Mutations of the PKHD1 gene include frameshift, nonsense, and out-of-frame splicing alterations that are consistent with a loss of function mechanism.
- The presence of 2 truncating mutations leads to the most severe phenotype, associated with death in the neonatal period.
- The PKHD1 gene product is a protein called polyductin or fibrocystin.
 - Transmembrane protein
 - Located mostly on the primary cilia and apical surface of renal tubular cells and cholangiocytes
 - It complexes with polycystin 1 and polycystin 2, the mutated proteins in autosomal dominant polycystic kidney disease (ADPKD).
 - Together, the complex is thought to function as mechanotransducer, detecting the shear force from urine and bile flow. Further studies will be needed to identify the biologic function of polyductin and to determine how mutations of the protein cause disease.

PATHOPHYSIOLOGY

- Ductal plate malformation is a characteristic histologic lesion of the liver, implying a disturbance of the normal development of the bile ducts.
- Hallmarks include the following:
 - Irregularly shaped, dilated, proliferating bile ducts, often described as staghorn shaped
 - Noninflammatory periportal fibrosis
 - Normal appearance of hepatocytes and lobular architecture
- The primary defect in ARPKD may be linked to ciliary dysfunction.
 - The ciliary structure is abnormal in ARPKD renal tubule cells and cholangiocytes.
- Developmental abnormalities involve the liver and kidneys and, less commonly, the vasculature and the heart.
- Portal hypertension is thought to result from the fibrosis in the portal tracts as well as, in some patients, from portal vein abnormalities.

COMMONLY ASSOCIATED CONDITIONS

- Portal hypertension leading to varices and hypersplenism
- Hepatomegaly
- Systemic hypertension
- Renal dysfunction
- Cholangitis
- Conditions associated with the finding of ductal plate malformation/CHF:
 - ARPKD; most frequent association
 - ADPKD, rare
 - Caroli syndrome (CHF and intrahepatic bile duct dilation)
 - Juvenile nephronophthisis
 - Congenital disorder of glycosylation type 1b (phosphomannose isomerase deficiency)
 - Congenital malformation syndromes
 - Meckel Gruber syndrome
 - Joubert syndrome
 - Jeune syndrome
 - Bardet-Biedl syndrome

DIAGNOSIS

HISTORY

- Severely affected patients are usually diagnosed in utero or shortly after birth due to massively enlarged cystic kidneys.
 - Prenatal renal dysfunction may result in pulmonary hypoplasia.
- Older patients may present with systemic hypertension or signs of portal hypertension and esophageal variceal bleeding.
- Patients may present with fever and jaundice (cholangitis) or, rarely, with signs of liver failure.

PHYSICAL EXAM

- Firm, enlarged liver with a prominent left lobe
- Splenomegaly
- Kidneys may be palpable on abdominal exam.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Thrombocytopenia and leukopenia are associated with hypersplenism.
- Liver enzymes and bilirubin are typically normal; transaminases may be mildly elevated in some patients.
- Usually, hepatic synthetic function (albumin, prothrombin time) is normal.
- May see elevated blood urea nitrogen and creatinine with renal involvement
- Genetic testing is available and consultation is recommended.

Imaging

- Complete abdominal ultrasound with Doppler
 - Increased hepatic echogenicity
 - Splenomegaly
 - Evidence of portal hypertension, portal vein patency, and decreased flow variability
 - Cystic kidneys
- Magnetic resonance cholangiopancreatography (MRCP) can further characterize the biliary system in Caroli syndrome.

Diagnostic Procedures/Other

- Liver biopsy
 - Characteristic histology of ductal plate malformation
 - If cholangitis is suspected clinically, send specimen for bacterial culture.

DIFFERENTIAL DIAGNOSIS

Varies with presentation. Usually, differential diagnosis is that of early cirrhosis or idiopathic portal hypertension.

TREATMENT

MEDICATION

Choleretic agents, including ursodeoxycholic acid, are used in bile stasis.

ADDITIONAL TREATMENT

General Measures

- Monitor growth, weight gain, nutritional status, and for vitamin A, D, E, K malabsorption.
- Suspected cholangitis should be managed with blood culture, antibiotics to cover gram-negative rods, and +/- liver biopsy. Some patients with chronic cholangitis may require antibiotic prophylaxis.
- Endoscopic variceal banding and/or sclerotherapy provide prevention and treatment of esophageal variceal hemorrhage in many cases.
- Activity
 - No contact sports if splenomegaly is present.
 - Spleen guard may be used to protect against injury from abdominal trauma.

SURGERY/OTHER PROCEDURES

- Portosystemic shunting may be needed but should be considered in the context of kidney function given ammonia disposal occurs renally.
- Liver transplant may be indicated for chronic cholangitis, recurrent bleeding, or progressive hepatic disease.
- Children who require transplantation should be considered for combined liver and renal transplantation.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Acute upper GI tract bleeding or melena requires urgent EGD for bleeding control, frequent Hgb/Hct checks, blood cultures, IV proton pump inhibitor, antibiotics, and possible need for octreotide drip in the ICU setting.
- Platelet count is the best predictor of pulmonary hypertension severity; an acute drop could indicate hepatorenal syndrome.
- Morbidity and mortality occurs mainly from variceal bleeding and cholangitis.
- Systemic hypertension and kidney function must be monitored.
- Early referral to a hepatologist, nephrologist, and transplant center is indicated in neonatal disease.

DIET

No restrictions are needed unless secondary to renal disease.

PROGNOSIS

- Substantial variability in severity and progression of clinical manifestation exists.
- Bleeding from varices is a major cause of morbidity and mortality.
- Ascending cholangitis with resultant sepsis is a major cause of morbidity and mortality.
- Those presenting during childhood have better prognosis compared to those presenting within the neonatal period.
- Need for eventual liver +/- kidney transplantation needs to be considered.

COMPLICATIONS

- Portal hypertension with hypersplenism and variceal bleeding (chronic, common)
- Cholangitis: acute and recurrent, significant cause of morbidity in Caroli syndrome
- Renal and/or hepatic failure
- Associated vascular anomalies in the liver and brain
- Increased risk of hepatocellular or cholangiocarcinoma in adulthood; screening in pediatric population is not warranted.
- Systemic hypertension owing to renal involvement

FAQ

- Q: Will other children of mine be affected?
- A: Maybe. The inheritance pattern is autosomal recessive, with the possibility of an affected sibling being 1:4.
- Q: Is my child at increased risk if he contracts viral hepatitis?
- A: Yes. The underlying liver disease places these patients at increased risk. They should be immunized against hepatitis A and B.
- Q: If my child has a fever, does she need to be seen by her doctor?
- A: Yes. Patients with CHF who have fever without an obvious source should be evaluated for possible cholangitis, at least by obtaining a blood culture and liver enzymes.

CONGESTIVE HEART FAILURE

Jondavid Menteer

BASICS

DESCRIPTION

Heart failure (HF) is the pathophysiologic state in which the heart is unable to pump sufficient blood to meet the metabolic demands of the body.

RISK FACTORS

- In utero
 - Arrhythmias: supraventricular or ventricular tachycardia, complete heart block (CHB)
 - Volume overload: atrioventricular (AV) valve regurgitation or arteriovenous malformation (AVM)
 - Primary myocardial disease: cardiomyopathy (dilated, hypertrophic), myocarditis
 - Anemia: Rh isoimmune disease, thalassemia, and twin-twin transfusion
 - Premature closure of ductus arteriosus with isolated right ventricular failure
- In neonates
 - Myocardial dysfunction: asphyxia, acidosis, myocarditis, hypoglycemia, cardiomyopathy (dilated, hypertrophic, ventricular noncompaction), ischemia (anomalous left coronary artery from the pulmonary artery), metabolic defects, or pressure overload imposed by aortic stenosis, pulmonary hypertension, or coarctation of the aorta
 - Volume overload: atrial septal defect (ASD) (large), ventricular septal defect (VSD) (large), patent ductus arteriosus (PDA) (moderate to large), truncus arteriosus, aortopulmonary window, anomalous pulmonary venous return, AVM in any location
 - Arrhythmias: supraventricular or ventricular tachycardia, CHB
 - Left heart inlet obstruction: mitral stenosis, cor triatriatum,

pulmonary venous obstruction

- Note: Certain cyanotic heart diseases such as hypoplastic left heart syndrome may present with elevated pulmonary blood flow or depressed systemic blood flow and minimal desaturation. These patients may have HF in the 1st day of life due to increased pulmonary circulation or due to shock from ductal closure.
- In infants
 - Myocardial dysfunction: cardiomyopathy (dilated, hypertrophic, restrictive, ventricular noncompaction), endocardial fibroelastosis, metabolic/mitochondrial diseases, myocarditis, Kawasaki disease, anomalous left coronary artery from pulmonary artery, or chronic pressure overload due to coarctation of the aorta or aortic stenosis
 - Volume overload: ASD (large), VSD, PDA, common AV canal defect, partial anomalous pulmonary venous connections.
 - Secondary causes: renal disease (volume overload, electrolyte disturbance), hypertension, hypothyroidism, sepsis
 - Arrhythmias: supraventricular or ventricular tachycardia, CHB
 - Pericardial effusion due to juvenile rheumatoid arthritis (JRA), systemic lupus erythematosus (SLE), other inflammatory diseases, or following repair of congenital heart disease (CHD)
- In childhood and adolescence:
 - Unrepaired CHD with volume and/or pressure overload
 - Repaired CHD with residual defects that result in volume and/or pressure overload
 - Acquired heart disease: pericarditis, myocarditis, endocarditis, acute rheumatic fever
 - Cor pulmonale (pulmonary hypertension, Eisenmenger syndrome, chronic lung disease)
 - Cardiomyopathy due to primary myocardial disease (dilated, hypertrophic, restrictive, ventricular noncompaction), chemotherapy (anthracyclines), radiation therapy, sickle cell anemia, thalassemia, neuromuscular disease (e.g., Duchenne or Becker muscular dystrophy)

GENERAL PREVENTION

- Limited use of anthracycline drugs in cancer therapy

- Prompt treatment (within 10 days) of streptococcal pharyngitis to prevent rheumatic fever
- SBE prophylaxis to prevent infective endocarditis

ALERT

- In patients with HF due to large left-to-right shunts, long-term spontaneous clinical improvement of HF with decreased murmur may indicate the development of pulmonary vascular disease (Eisenmenger syndrome), eventually leading to cyanosis.
- Care must be used in the administration of oxygen to the undiagnosed infant with heart disease. A patient with single-ventricle physiology (e.g., hypoplastic left heart syndrome) can have manifestations of HF and mild desaturation (92–98%). Providing oxygen in this situation can result in shock due to excessive pulmonary blood flow and inadequate systemic blood flow.

ETIOLOGY

- Low cardiac output HF (e.g., all cardiomyopathy, severe AV valve regurgitation)
- High cardiac output HF
 - Left-to-right shunts (e.g., ASD, VSD, PDA)
 - AVM
 - Severe anemia, beriberi, and hyperthyroidism

DIAGNOSIS

HISTORY

- Infants and neonates
 - Prolonged feedings associated with tachypnea, retractions, or diaphoresis
 - Emesis, inadequate caloric intake, irritability with feeding, and failure to thrive
 - Frequent respiratory infections. Orthopnea: “Spoiled baby” becomes distressed when supine.
 - Family history of HF or sudden unexpected deaths
 - Sweating, especially when supine/sleeping

- Childhood and adolescence
 - Exercise intolerance with exertional dyspnea
 - Palpitations or chest pain, especially during exercise
 - Chronic cough, wheezing, orthopnea, fatigue, weakness, anorexia, nausea, and edema
 - Gradual weight loss (anorexia, nausea, and increased metabolic demands)
 - Sudden weight gain (fluid retention)
 - Family history of HF or unexpected deaths
 - Sweating, especially when supine/sleeping

PHYSICAL EXAM

- Infants and neonates
 - Tachycardia
 - Gallop rhythm
 - Murmur of outflow obstruction, increased flow, AV valve regurgitation, VSD, or semilunar valve incompetence
 - Systolic click (semilunar valve abnormalities)
 - Abnormal second heart sound (fixed split, loud P₂ component)
 - Tachypnea, wheezing, crackles, rales
 - Nasal flaring, grunting, retractions
 - Abdominal or cranial bruit
 - Hepatomegaly, splenomegaly
 - Edema (periorbital)
 - Cool and/or mottled extremities
 - Poor capillary refill or pulses
- Children and adolescents
 - Tachycardia
 - Gallop rhythm
 - Murmur of outflow obstruction, increased flow, AV valve regurgitation, VSD, or semilunar valve incompetence
 - Loud second heart sound (P₂ component)
 - Hyperactive precordium, displaced PMI
 - Tachypnea, retractions
 - Wheezing (“cardiac asthma”) or rales
 - Jugular venous distension

- Hepatomegaly, splenomegaly
- Edema (periorbital, peripheral)
- Pulsus alternans, pulsus paradoxus
- Cool extremities, poor pulses, poor capillary refill
- Manifestations of Kawasaki disease, rheumatic fever, or endocarditis on mucous membranes, skin, and extremities

DIAGNOSTIC TESTS & INTERPRETATION

Diagnostic Procedures/Other

- Chest x-ray
 - Cardiomegaly, increased pulmonary vascular markings, hyperinflation, pleural effusion, Kerley B lines
- Electrocardiography
 - Abnormal P-waves
 - ST–T wave changes (ischemia, strain, inflammation/myocarditis)
 - Heart block (1st-, 2nd-, 3rd-degree) or tachyarrhythmia
 - Disease-specific findings: anomalous left coronary artery from the pulmonary artery (Q waves and inverted T waves in leads I and aVL, left ventricular hypertrophy, right ventricular hypertrophy, ischemic changes), restrictive cardiomyopathy, pericarditis pattern (diffuse ST segment changes, low voltages), hypertrophy (cardiomyopathy, CHD, storage disease)
- Echocardiography
 - Rule out CHD, evaluate coronary origins
 - Assessment of cardiac systolic and diastolic function
- Cardiac catheterization (in select cases)
 - Assessment of cardiac hemodynamics and anatomy
 - Endomyocardial biopsy may be helpful in the diagnosis of myocarditis, storage disease, or cardiomyopathy.
 - Electrophysiologic study to evaluate for the induction of arrhythmia
- Cardiac MRI or CT (in select cases)
 - Delineation of complex anatomic relationships
 - Right ventricular performance
- Other laboratory abnormalities
 - Blood gas: metabolic acidosis with elevated lactate
 - Chemistry: hyponatremia (dilutional), prerenal state

- Blood counts: anemia, leukocytosis, or leukopenia (e.g., viral myocarditis)
- Elevated erythrocyte sedimentation rate (e.g., rheumatic fever, Kawasaki disease)
- B-type natriuretic peptide (BNP or NT-BNP) elevation
- Urine: proteinuria, high urine specific gravity, microscopic hematuria
- Evaluation for metabolic causes of cardiomyopathy may include pyruvate, amino acid quantification, urine organic acids, carnitine, selenium, acylcarnitine profile, and liver function tests.
- Viral evaluation (adenovirus, coxsackievirus, Epstein-Barr virus, cytomegalovirus, parvovirus, echovirus)

DIFFERENTIAL DIAGNOSIS

- Tachycardia
 - Fever
 - Dehydration
 - Anemia
 - Supraventricular tachycardia or ventricular tachycardia without HF
 - Hyperthyroidism
 - Pericardial effusion
- Tachypnea
 - Respiratory disease or infection
 - Pulmonary venous obstruction
 - Acidosis (metabolic disease, poisoning)
 - Pneumothorax, pleural effusion
 - Carbon monoxide poisoning
- Edema
 - Hypoalbuminemia
 - Systemic inflammatory conditions/allergies
 - Hypothyroidism
- Sepsis
- Hepatomegaly
 - Liver disease
 - Storage disease
 - Extramedullary hematopoiesis

TREATMENT

GENERAL MEASURES

- Treatment of underlying cause
 - Surgical palliation or correction of CHD
 - Interventional cardiac catheterization (e.g., balloon dilation of aortic or pulmonary stenosis, coil embolization of PDA, device closure of ASD, dilation, or stenting of coarctation of the aorta)
 - Carnitine, coenzyme Q10, riboflavin, antioxidant replacement for select cardiomyopathies
 - Targeted medical treatment of endocarditis, myocarditis, anemia, rheumatic fever, Kawasaki disease, or hypertension
 - Radiofrequency ablation of tachyarrhythmia
 - Medical therapy for patients or mothers of fetuses with tachyarrhythmia
 - Pacing for bradyarrhythmias (e.g., heart block)
 - Control of chronic inflammatory conditions, such as SLE or JRA
- Management
 - Assessment of degree of illness:
 - If perfusion is compromised or acidosis is present, ICU care is indicated.
 - Hospitalization may be necessary to initiate treatment or prepare for surgery (e.g., coronary abnormalities, aortic coarctation).
 - Many patients diagnosed as outpatients with CHD or cardiomyopathy may not require inpatient treatment. Immediate consultation with a pediatric cardiologist should be arranged.
- Immediate management
 - General measures: activity restriction as indicated, oxygen as needed (not for patients with pulmonary overcirculation)
 - Tube feedings for severe failure to thrive or parenteral nutrition if there is concern for splanchnic circulation
 - Drainage of pericardial effusion, if needed.
 - Inotropic agents (digoxin, milrinone, dobutamine in refractory cases)
 - Intravenous immunoglobulin (IVIG) for myocarditis or Kawasaki

disease

- Loop diuretics (e.g., furosemide)
- Nesiritide (synthetic BNP) for refractory fluid overload
- Mechanical respiratory or circulatory support, if necessary (ventilator, extracorporeal membrane oxygenation, ventricular assist device)
- Chronic therapy
 - Digoxin
 - Loop diuretics (e.g., furosemide) for fluid overload/edema
 - Afterload reduction (e.g., angiotensin-converting enzyme [ACE] inhibitors)
 - Antagonism of activated neurohormonal systems: ACE inhibitor or angiotensin receptor blocker, spironolactone, beta-blocker
 - Anticoagulation or antiplatelet therapy (especially in restrictive and severe dilated cardiomyopathy)
 - Biventricular pacing/resynchronization in some cases
 - Heart and heart/lung transplantation in select cases

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Dependent on the etiology and degree of HF. Generally, initial follow-up of a patient with HF should be intensive, focused on assessing response to therapy. Initial follow-up generally weekly, spreading to monthly or quarterly over time, under the supervision of a pediatric cardiologist.
- Depending on the etiology and degree of HF, echocardiography, ECG, blood chemistry, BNP levels, INR, Holter monitoring, and chest radiography will be evaluated.

- Q23.4 Hypoplastic left heart syndrome

FAQ

- Q: My child has a large VSD and is prescribed digoxin and furosemide. Should I take salt out of his diet?
- A: No. Excessive salt restriction is seldom enforceable and is not necessary. A no-added-salt diet is generally sufficient.
- Q: What is the importance of tachycardia and bradycardia in HF?
- A: Tachycardia limits diastolic filling time and may result in decreased cardiac output. However, bradycardia may be poorly tolerated in patients with HF and a relatively fixed stroke volume who are dependent on heart rate to maintain an appropriate output. Either may be problematic for a patient in chronic HF. Most HF patients do not have as much heart rate variation as healthy people.

- Q: What are the major causes of death to HF patients?
- A: Younger children tend to die of progressive HF. Ventricular arrhythmias are the most common cause of sudden death in older children and adults with HF. Other causes of mortality include infection and stroke.
- Q: My patient has a normal blood pressure, but the cardiologist says more ACE inhibition is necessary. Why?
- A: Blood pressure is the weight that the myocardial muscle must “lift” with every beat. By decreasing the blood pressure as much as possible (short of causing dizziness or syncope), the work done by the heart and myocardial oxygen consumption are reduced. Reduction of the systemic blood pressure also potentially reduces the amount of left-to-right shunting through a VSD, PDA, and AP window.

CONJUNCTIVITIS

Shonul A. Jain

BASICS

DESCRIPTION

An inflammatory process of the conjunctiva, the membrane covering the eye and inside of the eyelids, manifested by erythema and edema, frequently with tearing and discharge. There is a wide range in severity and many potential causes. It is critical to rule out gonococcus infection because of the destructive nature of the eye disease and potential for vision loss.

EPIDEMIOLOGY

Incidence

- Children: Viral infection is the most common cause and is highly contagious.
- Neonates: Ophthalmia neonatorum, conjunctivitis in the 1st month of life, is the most common infection in neonates. Remains a significant cause of blindness in children worldwide. Chlamydia trachomatis is the most common infectious cause.

PATHOPHYSIOLOGY

- Results from bacterial, viral, allergic, or toxic activation of the inflammatory response that causes dilation and exudation from conjunctival blood vessels
- Pathology involves dilated conjunctival capillaries with leukocytic infiltration and edema of conjunctiva and substantia propria.

ETIOLOGY

- Ophthalmia neonatorum
 - If present in the first 24 hours of life, most likely due to chemical irritation from silver nitrate or povidone-iodine (e.g., Wokadine, Betadine) eyedrops
 - Gonococcal conjunctivitis is treatable if recognized early but

devastating if diagnosis is delayed or missed.

- Chronic Chlamydia infection can lead to scarring and corneal opacity. Chlamydial pneumonia develops in 20% of patients with chlamydial conjunctivitis.
- Bacterial
 - Agents include staphylococci, streptococci, Haemophilus, Moraxella, and Pseudomonas.
 - Serious complications of these are rare.
- Viral
 - Adenovirus is the most common agent.
 - Recurrent herpes simplex virus infection can lead to significant visual loss from corneal scarring, even with proper therapy.
 - Other viral etiologies usually follow a benign course but rarely can lead to conjunctival scarring.
- Allergic
 - IgE-mediated hypersensitivity response

DIAGNOSIS

HISTORY

- Ophthalmia neonatorum
 - Gonococcus: typically presents 2–4 days after birth with mucopurulent discharge
 - Chlamydia: typically presents 4–14 days after birth with mucopurulent discharge
- Bacterial
 - Eye redness and mucopurulent discharge. Patient may complain of sticky eyelids upon waking. Mild photophobia and discomfort may be present but are typically not painful.
- Viral
 - HSV ocular infection may present as conjunctivitis; often associated with corneal anesthesia, so painless. In neonates, it occurs 1–2 weeks after birth as unilateral serous discharge and conjunctival injection.
 - Other viral causes often present with upper respiratory symptoms,

fever, sore throat, eye redness, tearing, serous discharge, eyelid edema, and photophobia. Typically begins in one eye but spreads to the other within a few days. History of similar infection in siblings or contacts is common.

- Allergic
 - Bilateral itching and tearing; classically, a complaint of itching or foreign body sensation in an older child with red eyes

PHYSICAL EXAM

- General
 - Cornea is clear.
 - Vision, pupils, and ocular motility are normal.
 - Refer to an ophthalmologist for vesicular rash on eyelids or corneal changes, as the condition may be caused by herpes simplex virus and can be vision threatening.
- Bacterial
 - Wide range of clinical presentation, from mild hyperemia to significant injection and mucopurulent discharge (opaque and thick)
 - Injected conjunctiva, episcleral vessels, palpebral conjunctival papillae
 - Preauricular lymphadenopathy less common
- Viral
 - HSV ocular infection may involve corneal ulceration or dendritic or disciform keratitis.
 - Serous discharge (clear and watery)
 - May involve pseudomembrane formation, pinpoint subconjunctival hemorrhages, and palpable preauricular lymph nodes
- Allergic
 - Bilateral conjunctival edema and chemosis

ALERT

- Failure to diagnose gonococcal conjunctivitis may lead to corneal perforation or visual loss.
- HSV ocular infection is associated with a significant risk of blindness; have high suspicion for HSV with any recurrent unilateral eye redness, corneal changes, or vesicular rash on eyelids.

- Steroids can activate or accelerate unrecognized herpes simplex virus infection, and chronic use can lead to raised intraocular pressure or cataract formation.
- Chronic use of empiric broad-spectrum antibiotics for self-limited conjunctivitis can promote bacterial resistance, although less so than for systemic antibiotic administration.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Gram stain
 - Note: always for ophthalmia neonatorum
 - Gonococcus: gram-negative intracellular diplococcus
 - Chlamydia: intracytoplasmic, paranuclear inclusion bodies on Gram stain and conjunctival scraping with Giemsa stain for basophilic intracytoplasmic inclusion bodies
 - Viral or chemical: polymorphonuclear leukocytes without bacteria
- Culture
 - Viral: Cultures for HSV and adenovirus are not clinically useful.
 - Bacterial: blood agar and chocolate agar
 - Gonococcus: Thayer-Martin media
 - Chlamydia: Culture techniques are not widely available. However, they remain the gold standard for diagnosis. Specimens should be obtained using an aluminum-shafted Dacron-tipped swab and processed within 24 hours. A positive test is confirmed when the organism is identified using fluorescein-conjugated monoclonal antibody. Other equally effective methods involve polymerase chain reaction or direct fluorescent antibody.
- Conjunctival scrapings
 - Allergic: mast cells and eosinophils
- Serum tests
 - Allergic: IgE may be elevated.
 - Chlamydia: The diagnosis of chlamydial pneumonia can be made with a serum test but is not reliable for chlamydial conjunctivitis.

DIFFERENTIAL DIAGNOSIS

- Ophthalmia neonatorum

- Chemical conjunctivitis: noninfectious, mild, self-limited; result of silver nitrate or povidone-iodine administration
- Birth trauma: often unilateral subconjunctival hemorrhage, may have associated eyelid contusion, history of forceps use or difficult delivery
- Congenital glaucoma: mild redness, minimal discharge. Look for enlarged eye, cloudy cornea, tearing, and photophobia.
- Nasolacrimal duct obstruction: unilateral or bilateral discharge, may be clear to mucopurulent with reflux from nasolacrimal sac. Conjunctiva is usually white and nonerythematous.
- All conjunctivitis
 - Preseptal cellulitis: early eyelid edema/erythema; looks like conjunctivitis, especially in young children with a difficult exam. Motility deficit, proptosis, decreased vision, and afferent pupillary defect are consistent with orbital cellulitis.
 - Foreign body
 - Blepharitis: inflammation of eyelids, history of gritty/burning sensation, excessive tearing, significant eyelid swelling
 - Corneal abrasion: history of pain, associated trauma; significant tearing, photophobia, erythema. Diagnose with fluorescein and blue light.
 - Keratitis: signifies corneal infection; may have associated conjunctivitis. Primary herpes keratitis is associated with vesicular eyelid rash and pain. Consult an ophthalmologist. Bacterial keratitis may be caused by staphylococci, streptococci, and *Pseudomonas*; Lyme spirochete; or vitamin A deficiency.
 - Episcleritis: inflammation of the thick loose connective tissue between the clear conjunctiva and the white-appearing stroma of the sclera; rare disease in childhood; can be associated with rheumatologic disease
 - Scleritis: presents as red eye; severe disease involving inflammation of the sclera; rare in childhood; associated with systemic disease; requires oral or IV steroids
 - Iritis/uveitis: frequently unilateral, with or without a history of trauma; photophobia, decreased vision, and constant pain (except if

associated with juvenile rheumatoid arthritis). Contagious history is rare. Consult an ophthalmologist for full evaluation, including pupillary dilation.

- Systemic diseases with red eye
 - Varicella: ocular involvement in rare cases. Treat with antiviral medications.
 - Stevens-Johnson syndrome: secondary to viruses, mycoplasma, or adverse drug reaction. Mucous membrane involvement may lead to conjunctival bullae with risk of rupture and subsequent scarring.
 - Kawasaki disease: acute vasculitis. Classic symptoms include fever \times 5 days, plus 4 out of 5 of the following: bilateral, limbic-sparing nonexudative conjunctivitis; oropharyngeal changes (including strawberry tongue); cervical adenopathy; polymorphous rash; and extremity changes/swelling of palms and soles with peeling around nail beds.
 - Measles: presents with fever, rash, cough coryza, and conjunctivitis
 - Cat-scratch disease: Parinaud syndrome includes granulomatous conjunctivitis and adenopathy.

TREATMENT

MEDICATION

- Ophthalmia neonatorum
 - Gonococcus: ceftriaxone, 25–50 mg/kg/dose (max 125 mg) IV or IM as a single dose and ocular irrigation followed by topical 0.5% erythromycin ophthalmic ointment q.i.d. for 14 days. Also treat for Chlamydia.
 - Chlamydia: oral erythromycin suspension, 12.5 mg/kg/dose q6h for 14 days. Topical 0.5% erythromycin ophthalmic ointment q.i.d. both eyes for 14 days as above. (Povidone-iodine 1.25% ophthalmic drops q.i.d. can be used if other antibiotics are not readily available.)
 - Important to treat both of these conditions systemically as well as topically
- Bacterial
 - Often self-limited; however, studies have shown empiric antibiotic

treatment can shorten duration of symptoms and reduce transmission.

- Treatment includes erythromycin ointment, sulfacetamide 10%, polymyxin-trimethoprim, fluoroquinolone, or azithromycin drops.
- Viral
 - Herpes simplex: topical trifluorothymidine (Viroptic solution), 1 drop q2h while awake (max 9 drops/24 h) until reepithelialization of ulcer; then 1 drop q4h for 7 days (do not exceed 21 days of treatment) with or without systemic acyclovir
 - Topical glucocorticoid therapy is contraindicated.
 - Other viral: over-the-counter antihistamine or decongestant drops for comfort
 - Cidofovir has recently been considered as a potential antiadenoviral therapy, but its clinical use is limited by local toxicity to the skin, eyelids, and conjunctiva.
- Allergic
 - A new class of topical mast cell stabilizers such as olopatadine b.i.d. is effective for more involved cases.

ADDITIONAL TREATMENT

General Measures

- Ophthalmia neonatorum
 - Cases of suspected gonococcal conjunctivitis should be hospitalized for IV antibiotics and workup for sepsis.
 - For suspected chlamydial infection, topical and oral therapy is usually appropriate.
- Bacterial
 - Usually self-limited, but treatment may help shorten course and prevent spread of infection. Contact lens users should remove lenses until infection clears and consider use of fluoroquinolone.
- Viral
 - Suspected HSV warrants hospitalization for IV antiviral therapy.
 - For suspected adenovirus, children should stay home from school until discharge is minimal and discomfort has subsided; cool compresses for comfort
- Allergic

- Remove offending allergen if possible.
- Mild symptoms can be treated with preservative-free artificial tears. Consider topical or systemic antiallergy medicine if symptoms persist.
- Consider treating other atopic conditions which are often present.
- Chemical
 - Close observation only. Remove offending agent; self-limited

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Daily follow-up is necessary for gonococcus, Chlamydia, and herpes simplex virus.
- For epidemic viral conjunctivitis, frequency is dictated by severity (daily to weekly).
- For allergic conjunctivitis, follow-up can be made after a few weeks of treatment.
- No office follow-up is recommended for routine conjunctivitis.
- Follow atypical conjunctivitis closely until a more serious disease can be excluded.
- A nonresponsive or worsening condition needs ophthalmic consultation.

COMPLICATIONS

- Significant complications are extremely rare for common bacterial, viral, or allergic conjunctivitis.
- Blindness may result from untreated neonatal conjunctivitis or from recurrent HSV ocular infection.

CODES

ICD10

- **H10.9 Unspecified conjunctivitis**

- B30.9 Viral conjunctivitis, unspecified
- P39.1 Neonatal conjunctivitis and dacryocystitis

FAQ

- Q: Is conjunctivitis contagious?
- A: All infectious conjunctivitis is contagious but to varying degrees. Viral or epidemic keratoconjunctivitis (EKC) is the most contagious. Careful handling of secretions, tissues, towels, and bed linens and strict hand washing usually prevent spread. Wipe surfaces with isopropyl alcohol or dilute bleach to prevent recontamination. Gonococcus, Chlamydia, and herpes simplex virus can be transmitted through infected discharge or secretions, but this is less common. The most common source is the infected birth canal.
- Q: Should the patient with “pink eye” (non-Gonococcus, non-Chlamydia, non-herpes simplex virus conjunctivitis) be treated with empiric antibiotics?
- A: There is some benefit to empiric antibiotic treatment in bacterial conjunctivitis but not in viral or allergic etiologies. Practically, it is often difficult to distinguish viral and bacterial conjunctivitis based on symptoms alone, and return to school is often contingent on initiation of antibiotic therapy. Providers should be aware that empiric treatment with topical antibiotics can cause harm in the case of sulfa-containing compounds. Antibiotic toxicity, including Stevens-Johnson reactions, can occur from sulfa antibiotics, and use of antibiotics long term promotes selection of resistant strains of bacteria. Empiric treatment also increases manipulation of the infected eye and thus increases the risk of spread.
- Q: How long is the patient with pink eye (non-Gonococcus, non-Chlamydia, non-herpes simplex virus conjunctivitis) contagious, and when can the patient return to school?
- A: The organism can be recovered from the eye for up to 2 weeks after onset of symptoms, demonstrating that patients are infectious during this time. Practically, children should probably be kept out of school at least 24 hours after onset of therapy, if indicated, ideally until discharge is minimal and discomfort has subsided.

CONSTIPATION

Jay Fong

BASICS

DESCRIPTION

Delay or difficulty in defecation; infrequent (<2) stools per week, and resulting in pain, rectal bleeding, as well as fecal soiling. May also refer to a decrease in frequency of bowel movements compared with the patient's usual bowel pattern.

GENERAL PREVENTION

- Dietary measures: high-fiber diet, plenty of fluids, fruits, and vegetables; avoidance of excessive caffeine and milk (calcium) intake
- Regular physical activity

PATHOPHYSIOLOGY

- Delay in colonic passage and/or retention of stool allows fluids mixed in stool to be resorbed across cellular membranes, increasing stool caliber and leading it to be harder in consistency.
- Decreased motility leads to a buildup of desiccated stool causing painful defecation that leads to ongoing stool retention.
- As the rectosigmoid enlarges with retained stool, a child's ability to sense rectal fullness diminishes, and he or she may not appreciate the need to defecate.
- Often there is a family history of motility disturbances or constipation.

ETIOLOGY

- Most patients have idiopathic or functional constipation with no identifiable cause.
- Personal history of constipation may be traceable to an acute event (i.e., passage of large, painful stool) followed by chronicity.
- Intentional or unintentional withholding of stool may result in hard stools, anal pain, and fissures that perpetuate and lead to constipation. Rectal dilatation, decreased sensation of the urge to defecate,

shortening of the anal canal, decreased tone of the external anal sphincter, and encopresis can result.

- Precipitating events may include the following:
 - Transition from breast milk to cow's milk
 - Excessive cow's milk intake
 - Insufficient water intake
 - Refusal to use toilets outside the home
 - Premature toilet training
 - Perianal streptococcal infection
 - Food allergies
 - Transient viral illness (diarrhea followed by constipation)
- Constipation also can be caused by anatomic anomalies in the lower GI tract, decreased propulsion, increased rectal sensitivity threshold, a functional outlet obstruction (muscular spastic levator ani or impaired relaxation of the puborectalis).
- Neurologic causes:
 - Abnormalities of the myenteric plexus
 - Intestinal pseudoobstruction
 - Congenital aganglionosis (Hirschsprung disease)
 - Visceral neuropathies
 - Visceral myopathies
 - Familial dysautonomia
- Lesions of the spinal cord can result in loss of rectal tone and sensation and reduced anal closure, affecting the sacral reflex center (e.g., meningocele, myelomeningocele, tethered cord).
- Anatomic disorders of anus and rectum (stricture, stenosis, mass, ectopic anus, imperforate anus, fistula)
- Endocrine abnormalities (hypothyroidism), drugs, electrolyte abnormalities

DIAGNOSIS

HISTORY

- Question: What was the timing after birth of passage of meconium?
 - If it is delayed for >48 hours, consider Hirschsprung disease.

- Is the child able to pass a bowel movement unaided by a suppository or enema?
 - If rectal stimulation is required for passage of a bowel movement, consider Hirschsprung disease or habituation to rectal stimulation.
- What are the size, frequency, and consistency of bowel movements?
 - 1–3 normal (in size and consistency), painless bowel movements may be passed every 1–3 days. The size of bowel movements reflects the caliber of the colon.
- Does the child experience frequent urination, bed-wetting, or urinary tract infections?
 - Chronic UTIs are frequently linked to chronic constipation.
- Does fecal soiling occur?
 - Soiling occurs with stool impaction or with nerve damage involving the anus.
- Is there the presence of rectal sensation?
 - Patients with long-standing constipation or stool withholding may develop a dilated rectum and lose the sensation of rectal distention.
- Is there a history of painful bowel movements or rectal fissure?
 - Pain with defecation and/or fissuring can further lead to withholding secondary to fear of painful bowel movements.
- Is the child experiencing any stressful events (i.e., new sibling, family death)?
 - Stress can precipitate stool withholding.
- Is there an unsteady gait?
 - This may suggest neuromuscular problems.
- Did the child experience difficult toilet training?
 - May be associated with encopresis

PHYSICAL EXAM

- General: Look for evidence of systemic illness and alarm signals: weight loss, anorexia, delayed growth, delayed passage of meconium, urinary incontinence, passage of bloody stools (in the absence of anal fissure), fever, vomiting, and diarrhea.
- Abdomen: abdominal distention (indicative of the presence of stool or gas), presence of stool masses (size, location), distended bladder, and bowel sounds (may be decreased in intestinal pseudoobstruction)

- Rectal examination
 - Perianal soiling
 - Size and position of anus (evaluate for signs of imperforate, stenosed, or ectopic anus)
 - Presence of skin tags and fissures
 - Perianal or anal erythema (streptococcal proctitis)
- Evidence of child abuse
- Digital examination is not recommended to diagnose functional constipation. If suspicious for other etiologies, can use to assess anal tone (long and tight anal canal in Hirschsprung); amount and consistency of stool; size of rectum (dilated rectum with chronic constipation; tight and empty anus with Hirschsprung disease); presence of blood
- Absence of anal wink or cremasteric reflex suggests neurologic abnormalities.
- Neurologic examination: decreased reflexes in the lower extremities
- Back: Check for sacral dimple, tuft of hair (underlying sacral abnormality), flat buttocks, and patulous anus.

ALERT

- Grunting baby syndrome: Infants cry, scream, and draw up their legs during a bowel movement. They respond to rectal distention by contracting their pelvic floor. This is not constipation.
- Always rule out an organic cause.
- Always consider medications as a cause.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

Testing for possible underlying thyroid disease and/or celiac disease may be recommended in patients with likely functional constipation. Other lab testing is not routinely recommended.

Imaging

- Abdominal radiography:
 - May demonstrate presence or absence of fecal impaction
 - Should not be used routinely for the evaluation of functional constipation

- Water-soluble contrast enema:
 - An unprepped study is useful to diagnose Hirschsprung disease.
 - A prepped study is useful to diagnose a stricture.
 - Most patients with constipation will not require this test, especially those with functional constipation.

Diagnostic Procedures/Other

- Measurement of abdominal transit time with radio-opaque markers may help discriminate between children with and without clinical constipation, but evidence does not support its routine use in diagnosis.
- Anorectal manometry: analyzes rectal sensation, resting and squeezing pressures, and pelvic floor dyssynergia (anismus)

DIFFERENTIAL DIAGNOSIS

- Celiac disease (more likely in younger children)
- Hypothyroidism, hypercalcemia, hypokalemia
- Diabetes mellitus
- Dietary protein allergy
- Drugs, toxics:
 - Opiates, anticholinergics, antidepressants, chemotherapy, and heavy metal ingestion (lead)
- Vitamin D intoxication
- Botulism
- Cystic fibrosis
- Hirschsprung disease
- Anal achalasia
- Colonic inertia
- Anatomic malformations (imperforate anus, anal stenosis)
- Pelvic mass (sacroccygeal teratoma)
- Spinal cord anomalies, trauma, tethered cord
- Abnormal abdominal musculature (prune belly, gastroschisis, Down syndrome)
- Pseudoobstruction
- Multiple endocrine neoplasia type 2B

TREATMENT

GENERAL MEASURES

- Treatment of functional constipation:
 - Disimpaction
 - The use of polyethylene glycol (e.g., MiraLAX or other generics) with or without electrolytes orally at 1–1.5 g/kg/24 h for 3–6 days is recommended as first line for children presenting with impaction.
 - If the patient is not tolerating PO, enemas may be required for initial disimpaction.

ALERT

Multiple phosphate enemas can cause severe electrolyte imbalances (hyponatremia, hypokalemia, hypocalcemia, hypomagnesemia).

- Children >2–3 years of age require adult-size enemas, whereas younger children require pediatric-size enemas. Enemas can be given once per day for 3–6 days.
 - Evacuation
 - Following rectal disimpaction, further evacuation can be achieved by using polyethylene glycol solution (Go-Lytely), orally or via nasogastric tube over 6–8 hours until the effluent is clear.
 - Maintenance stool softeners:
 - Infants ≤6 months of age may be given sorbitol or pectin-containing juices, lactulose, or Karo syrup.
 - Children >6 months of age may be given lactulose (0.7–2 g/kg/24 h [1–3 mL/kg/24 h], max 40 g/24 h [60 mL/24 h]) or MiraLAX (0.5–1 g/kg, max 17 g/24 h).
 - Mineral oil or Kondremul (>15 months of age 1–3 mL/24 h, >6 years 10–25 mL/24 h) is added as an adjunctive lubricant to aid in the passage of stool, but contraindicated in children <15 months as well as in children at risk for aspiration.
- Rescue stimulant laxatives:
 - Bisacodyl or senna may be used as a stimulant laxative for short period of time. Long-term use has been associated with colonic nerve damage in adults.

- Diet: A balanced diet of whole grains, fruits, and vegetables is recommended. A normal-fiber diet is recommended (toddler 14 g/24 h; school-aged 17–25 g/24 h; adolescent 25–31 g/24 h). Fiber should be increased gradually to minimize side effects of flatulence. Caffeine and excessive milk-product intake (>16 oz/24 h of milk) may be constipating.
- Fluid intake: A normal fluid intake is important.
- Toilet sitting: Regular toilet sitting twice a day for 10 minutes, preferably 15–20 minutes after meals, is a key step in retraining the bowel.
- Calendar: It is important to keep a record of stools, accidents, toilet sitting, and medications in order to identify causes of failure.
- Biofeedback has not been shown to be helpful in patients who fail conventional therapy and who have abnormalities on anorectal manometry.
- There may be some benefit in referring a patient with constipation and behavioral abnormalities to a mental health specialist.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Schedule regular visits to make certain therapy is maintained, decreasing the frequency of visits when patient is doing well.
- Parents should call when problems develop.
- Compliance and good follow-up are key to successful management of constipation.

PROGNOSIS

For functional constipation, the success rate is variable (45–90%).

Presence of abdominal pain at the time of presentation, close follow-up, and maintenance use of stool softeners are good prognostic factors.

Presence of soiling, use of stimulant laxatives, and lack of follow-up were associated with failure.

COMPLICATIONS

- Anal fissures: Infrequent hard stools can cause a tear of the anal

mucosa, causing pain and withholding.

- Encopresis: Chronic constipation leads to progressive rectal dilatation and decreased rectal sensation. Fecal impaction results in secondary soiling or encopresis.
- Intestinal obstruction: manifests as vomiting, abdominal pain, and constipation. Abdominal radiograph films show intestinal obstruction and presence of large amounts of stool.
- Sigmoid volvulus: A chronically constipated child may present with symptoms of acute abdomen, fever, tender abdomen, and palpable mass. Abdominal radiograph shows obstruction in the colon. Barium enema may be both diagnostic and therapeutic by achieving reduction.
- Treatment of complications:
 - Encopresis (soiling or diarrhea): Disimpaction and clean out as necessary, followed by treatment of constipation, is recommended (see previous discussion).
 - Intestinal obstruction from fecal mass: Presents with vomiting, abdominal pain, and constipation. Abdominal radiograph film shows intestinal obstruction. Make nil per os (NPO), provide IV fluids, and rule out an acute abdomen. Then give enemas and clear out stool from below. Avoid oral laxatives or a polyethylene glycol solution in a case of obstruction.
 - Sigmoid volvulus: Chronically constipated child with symptoms of acute abdomen, fever, tender abdomen, and palpable mass. Abdominal radiograph shows obstruction in the colon. Contrast enema may reveal and possibly reduce a volvulus.

- K59.09 Other constipation
- K59.02 Outlet dysfunction constipation

FAQ

- Q: When is constipation an emergency?
- A: When intestinal obstruction, sigmoid volvulus, or Hirschsprung enterocolitis occurs.
- Q: Does polyethylene glycol-3350 taste bad?
- A: Advantages of polyethylene glycol-3350 include its lack of taste, smell, or odor and that it can be mixed in any liquid.

CONTACT DERMATITIS

Jocelyn H. Schiller

BASICS

DESCRIPTION

An acute or chronic inflammation of the dermis and epidermis as result of either direct irritation to the skin (irritant contact dermatitis) or delayed-type (type IV) hypersensitivity reaction to a contact allergen (allergic contact dermatitis)

EPIDEMIOLOGY

Incidence

Incidence in children is not known.

Prevalence

- Irritant contact dermatitis: Most cases of contact dermatitis (>80%) are irritant contact dermatitis.
 - Skin reactivity is highest in infants and tends to decrease with age.
- Allergic contact dermatitis
 - Because children have less time to develop sensitivities, it is less common in infants and children than in adults.
 - Prevalence increases with age.
 - Overall prevalence is ~13–23% and has been increasing in children, perhaps due to more frequent exposure to allergens at a younger age or improved diagnosis.

RISK FACTORS

- Irritant contact dermatitis
 - Frequent hand washing or water immersion
 - Atopic dermatitis: Chronically impaired barrier function increases susceptibility to irritants.
 - Genetic factors
 - Environmental factors such as cold/hot temperatures or high/low humidity disrupt the skin barrier.
- Allergic contact dermatitis

- Atopic dermatitis
- Genetic factors
- Increased exposure to allergens

GENERAL PREVENTION

Minimize contact exposure to known or potential irritants and allergens.

PATHOPHYSIOLOGY

- Irritant contact dermatitis does not involve an immune response and thus can occur with the first exposure to the irritant. Multiple mechanisms are involved, including the following:
 - Disruption of the epidermal barrier by chemicals (soaps, detergents) or physical irritants (moisture, friction)
 - Damage to cell membranes and cytotoxic effect on skin cells
 - Chronic exposure may stimulate cell proliferation, resulting in acanthosis and hyperkeratosis. Postinflammatory hypo- or hyperpigmentation may result.
- Allergic contact dermatitis requires initial exposure and sensitization to an allergen and only occurs in susceptible individuals. Repeated exposure leads to the development of a type IV hypersensitivity reaction.
- Both processes result in nonspecific findings of dermal and epidermal edema and inflammation and may be indistinguishable from other forms of inflammatory dermatitis.

ETIOLOGY

- Irritant contact dermatitis
 - Frequent hand washing or water immersion
 - Soaps and detergents
 - Saliva (lip licking or thumb sucking)
 - Urine and feces (see “[Diaper Rash](#)”)
 - High concentrations of most chemicals can induce irritant contact dermatitis, whereas mild irritants may induce inflammation only in susceptible individuals.
- Allergic contact dermatitis
 - Nickel and other metals (gold, cobalt)
 - Hair products (ammonium, 5-diamine)

- Solvents (toluene-2)
- Additives to medications, cosmetics (thimerosal, mercuric chloride)
- Rubber
- Fragrances (Balsam of Peru)
- Clothing dyes
- Formaldehydes
- Topical antibiotics (neomycin, bacitracin)
- Plants (Toxicodendron species; e.g., poison ivy, poison oak, and poison sumac, which contain the allergen urushiol)

DIAGNOSIS

HISTORY

- Patients may present with either acute or chronic localized, pruritic dermatitis.
- Patients should be asked about all chemicals and potential irritants or allergens to which they are intermittently or frequently exposed.
- Many patients are unable to associate a specific allergen with symptom development.
- Timing of symptoms
 - Irritant contact dermatitis: immediate inflammation
 - Allergic contact dermatitis: inflammation 48–72 hours but occasionally several days after exposure
- Location of skin changes may provide clues, as reactions are typically localized to the areas that come in contact with the allergen.

PHYSICAL EXAM

- Irritant contact dermatitis
 - Acute: ranges from mild skin dryness and mild erythema to erythematous papules and patches, edema, vesicles, and oozing; in severe cases, may result in a chemical burn (skin necrosis)
 - Chronic: erythema, dryness, lichenification, hyperkeratosis, and cracking
 - A perioral rash often signifies an irritant contact dermatitis from lip licking.

- Allergic contact dermatitis
 - Acute: pruritus, erythema, and edema with vesicles or bullae that often rupture, leaving a crust
 - Chronic: lichenification, erythema, scaling
- Often an unusual pattern or distribution that correlates with pattern of exposure (e.g., a linear pattern as patient brushes against poison ivy, round lesion on abdomen where skin contacts nickel button on jeans)
- Autoeczematization or “id” reaction: A more generalized dermatitis may develop distal to the original site of contact 1 or more weeks after the initial localized dermatitis.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

In general, routine laboratory testing is not helpful in confirming the diagnosis of contact dermatitis.

Diagnostic Procedures/Other

- Formal epicutaneous patch testing distinguishes irritant and allergic contact dermatitis and identifies inciting allergens; may be performed by clinicians experienced in the interpretation of the test
- The patch test involves the controlled exposure of multiple allergens to the skin. Positive reactions manifest with the development of erythema, edema, and vesicles at the site of exposure, usually within 48–96 hours. It may be performed using a standard panel of allergens or by the application of selected allergens at the discretion of the specialist.
- Patch testing for poison ivy or oak is not recommended because reactions may be severe.

Pathologic Findings

- Skin biopsy is rarely necessary but may help differentiate between contact dermatitis and psoriasis or other inflammatory dermatoses.
- Skin biopsy findings may not be specific, and histopathologic features may not differentiate irritant from allergic contact dermatitis.

DIFFERENTIAL DIAGNOSIS

- Infection

- Impetigo and cellulitis: Bacterial infections of the skin (*Staphylococcus aureus* or group A *Streptococcus*) may manifest as erythematous, edematous, crusted patches and plaques. Pustules and/or deep-seated inflammatory nodules may be present. Infection is usually associated more with pain and tenderness than with pruritus.
- Fungal infection: KOH examination can clarify the diagnosis.
- Scabies: intensely pruritic papules and nodules with a predilection for the hands and feet (especially the web spaces), the axillae, and the groin. Close contacts are often affected.
- Herpes simplex virus may present with vesicles but is less erythematous and pruritic and more painful.
- Metabolic
 - Acrodermatitis enteropathica: a genetic or acquired zinc deficiency with characteristic bullae and erosions involving hands, feet, and periorificial areas (perioral, periorcular, and perineal). Associated with failure to thrive, diarrhea, and alopecia
- Immunologic
 - Atopic dermatitis: It may favor the face and extremities or occur more diffusely with truncal involvement; usually spares diaper, perinasal, and periorcular areas; usually symmetric; associated with erythematous, excoriated, and crusted papules, patches, and plaques and with chronic pruritus, often worse at night; often accompanied by a personal or family history of atopy
 - Seborrheic dermatitis: usually affects infants <1 year of age or adolescents; erythema and greasy scaling patches that favor scalp, face, ears, and intertriginous areas; usually asymptomatic
 - Nummular eczema: a chronic, often intensely inflammatory and pruritic dermatitis with multiple round, crusted, edematous, erythematous patches and plaques, often on extremities
 - Psoriasis vulgaris: a chronic dermatitis with recurrent well-defined erythematous plaques with silvery scale; commonly affects scalp, elbows, and knees; nail changes may be present.
- Other
 - Ichthyoses: diffuse, severely dry, scaly, and hyperkeratotic skin;

acquired or inherited

- Pityriasis rosea: may begin with a single round, sharply demarcated, pink “herald” patch on the torso which becomes scaly and develops central clearing, followed by crops of oval lesions on the trunk and proximal extremities
- Child abuse: inflicted trauma or burns

TREATMENT

MEDICATION

First Line

- Topical corticosteroids may help with the pruritus and inflammation associated with both acute and chronic contact dermatitis. Some mild cases may not require treatment and may self-resolve in 1–2 weeks.
- In irritant contact dermatitis, topical corticosteroids are controversial, as efficacy has not been evaluated in randomized controlled studies. Potential benefits must be weighed against the adverse effects.
- Milder forms not involving the face or flexural areas can be treated with class 3–5 topical corticosteroids for a short duration.
- For severe or chronic contact dermatitis with lichenification not involving the face or flexural areas, a medium- to high-potency topical corticosteroid (class 2–4) should be used for a short duration (2 weeks).
- If involving the face or flexural areas, medium- to high-potency topical corticosteroids should be avoided; instead, use a low-potency topical corticosteroid (class 6 or 7).
- Systemic antihistamines (diphenhydramine or hydroxyzine) are generally not necessary but can be considered if pruritus is extreme. There is no evidence that topical antihistamines are useful in treatment of pruritus.
- In severe cases involving a large body surface area or associated with significant facial, genital, or extremity edema, a short course (7–10 days) of systemic corticosteroids (prednisone 1–2 mg/kg/24 h) may be appropriate, with tapering over 1–2 weeks to avoid a rebound of the dermatitis.

Second Line

The intermittent use of a topical calcineurin inhibitor such as tacrolimus or pimecrolimus, which have anti-inflammatory and steroid-sparing properties, may be considered as adjunctive therapy in patients with chronic contact dermatitis. These agents are less effective than mid-potency corticosteroids, and the FDA issued an advisory about the possible link between topical use of calcineurin inhibitors and cancer. They should not be used in children younger than 2 years of age.

ADDITIONAL TREATMENT

General Measures

- The most effective treatment involves identification and avoidance of the offending allergens or exposures. This often requires extensive education of the patient and family regarding potential sources of exposure.
- Emollients restore epidermal barrier function. Petrolatum-based products are preferred to emollients containing lanolin or fragrances to reduce the risk of contact sensitization. Frequent application is recommended.
- Prompt bathing with soap and water immediately after exposure to poison ivy, oak, or sumac may help reduce exposure to the allergen in susceptible individuals.
- Chemical inactivators of urushiol may decrease dermatitis, but oil-removing compounds and soap also decrease dermatitis when used promptly after exposure.
- Acute allergic contact dermatitis: Application of cool compresses and shake lotions with drying properties (e.g., calamine lotion) can be helpful. Products containing colloidal oatmeal may also be helpful in soothing inflamed skin.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

Patients who do not improve after 1–2 weeks of therapy should be

reevaluated.

PATIENT EDUCATION

Prevention

- Patients should be instructed on allergen avoidance, including the use of protective gloves and clothing where appropriate.
- Barrier creams containing quaternium-18 bentonite (bentoquatam 5%) may prevent exposure to the allergen in poison ivy if applied prior to anticipated exposure. Protective clothing may be helpful but can harbor the allergenic resin for many days.

PROGNOSIS

Complete resolution can be expected after appropriate treatment and elimination of further exposure to the allergen.

COMPLICATIONS

Generally, there are no long-term complications, although secondary bacterial infections may occur.

CODES

ICD10

- L25.9 Unspecified contact dermatitis, unspecified cause
- L24.9 Irritant contact dermatitis, unspecified cause
- L23.9 Allergic contact dermatitis, unspecified cause

FAQ

- Q: Can the fluid from blisters caused by poison ivy spread the rash to other parts of the body?
- A: The contents of blisters from rhus dermatitis are not contagious. After exposure is eliminated, new lesions may appear because of the variable sensitivity of various areas of the body to the allergen.
- Q: How does saliva cause a perioral rash in some kids?
- A: “Lip-licker dermatitis” is an irritant dermatitis that results from chronic and/or excessive exposure to moisture. It is not caused by any specific substances in the saliva.

CONTRACEPTION

Michelle Forcier

BASICS

DESCRIPTION

- Prevention of conception or pregnancy. Ideal contraceptive is 100% effective, has no side effects, is easily reversed, and is readily used by adolescents.
- Efficacy issues:
 - In practice, contraceptive efficacy is based on two core concepts:
 - Adherence or ability to adequately “do” the method
 - Continuation or length of time over which patient uses method
 - Adherence and continuation improved by superior effectiveness of long-acting reversible contraceptives (LARCs), such as intrauterine devices (IUDs) or subdermal implants. LARCs have failure rates of less than 1% and approximately 80% continuation rates.
 - The most effective methods should be offered as 1st-line contraceptive options for sexually active teens.

Methods of contraception:

- LARCs:
 - Etonogestrel implant
 - Single-rod subdermal implant containing 68 mg of progestin etonogestrel. Implant provides contraception for 3 years.
 - Benefits: easy to insert and remove device, insertion site easy to access (nondominant upper arm)
 - Can be placed in not yet sexually active patients considering future sexual activity or for heavy or painful menses
 - Levonorgestrel-releasing (IUD)
 - T-shaped polyethylene IUDs containing progestin hormones
 - Ovulation may be suppressed in some women but is not the main mechanism of action, with between 45–75% of women ovulating on the 52 mg device, and almost all women ovulating on the lower dose LNG-IUD.

- Ovulation on the lower dose LNG-IUD may result in less amenorrhea and more regular menses which can be a desired effect for some women.
 - Mirena[®] contains 52 mg of levonorgestrel and a release rate of 20 mcg/day and is FDA-approved for use for up to 5 years but is effective up to 7 years. Significantly reduces menstrual bleeding and dysmenorrhea
 - Skylar[®] IUD is slightly smaller, 28 mm × 30 mm, and contains 13.5 mg levonorgestrel with a release rate of 5–14 mcg/day and decline to 5 mcg/day after 3 years.
- Copper T380 IUD
 - Contraceptive effect related to in utero oxidation with release of copper ions.
 - FDA-approved for use up to 10 years but may be effective for up to 12 years
 - May also be placed as very effective emergency contraceptive and then retained for ongoing pregnancy prevention
- Moderate-duration contraceptives:
 - Depot-medroxyprogesterone acetate (DMPA or Depo-Provera)
 - IM injection administered every 12 weeks. Failure rates in real-world settings estimated as low as 6%, likely much higher for adolescents.
 - 1-year continuation: 56% for users of all ages, likely lower for teens
 - Effective up to 14 weeks, so patients within that dosing window do not need additional pregnancy testing before readministration
- Short-acting estrogen-progestin (EP) contraceptives:
 - General issues:
 - Typically use both estrogen (to minimize break-through bleeding) and progestin (to block ovulation) in variety of delivery systems
 - Typical use failure rates at 9% but higher in adolescent populations. Continuation rates are 67%, likely lower in teens.
 - Some EP agents such as combined oral contraceptive pills (COCs) and vaginal rings may be used almost continuously for extended cycling. Such extended cycling may be useful for

- patients with dysmenorrhea, heavy periods, anemia, or times (life events) when delaying a period desired.
- Combined oral contraceptive pills (COCs):
 - ▢ Monophasic COCs contain fixed doses of estrogens (ethinyl estradiol [EE]) and progestins. Phasic COCs vary doses of estrogens, progestins, or both. No practical difference between monophasic and phasic COCs.
 - ▢ 99.9% effective with perfect use but real-life use, difficulties with adherence, and continuation significantly reduce effectiveness.
 - ▢ Benefits: reduce incidence of endometrial and ovarian cancers after as little as 3 months of use, protect against salpingitis (PID) and subsequent ectopic pregnancies, and decrease incidence of benign breast disease and dysmenorrhea
 - ▢ Effective treatment for abnormal or heavy uterine bleeding (AUB), perimenstrual mood and physiologic symptoms, hygiene and behavior changes around menses for some developmentally delayed individuals, and sequelae of hyperandrogenism or polycystic ovary syndrome (AUB, hirsutism, acne)
 - Transdermal patch
 - ▢ Contains ethinyl estradiol and norelgestromin. Each patch left in place for 7 days, changed weekly, allowing 1 patch-free week per month for menses; convenient due to once-weekly change
 - ▢ Typically not recommended for extended cycling, as studies demonstrate 60% more circulating estrogen than with other EP methods
 - ▢ Unclear if this increases vascular thrombotic event (VTE) risk
 - Vaginal ring
 - ▢ Soft, flexible, polymer ring containing ethinyl estradiol and etonogestrel
 - ▢ FDA-approved for vaginal insertion for 3 weeks then removed for 1 week for menses
 - ▢ May be effective over a 4-week insertion and for extended cycling
 - ▢ Benefits: avoidance of 1st-pass liver effects and lower hormone doses

- Emergency contraceptives (EC): postcoital contraceptives, “morning-after” pills
 - General issues:
 - Safe but less effective (estimated 75%) than other hormonal/inserted contraceptives
 - Not abortifacient but blocks ovulation, as do other hormonal methods of contraceptives
 - Advance provision improves patient use but does not decrease overall pregnancy rates over time.
 - May be offered to all women using short- or moderate-acting contraceptives
 - Ulipristal acetate (UPA) 30 mcg
 - Administered in a single oral dose up to 5 days post unprotected sex with equal effectiveness across time
 - Is more effective in overweight or obese women than progestin methods
 - Not carried by all pharmacies, both community and hospital based as of 2015
 - Often requires insurance preauthorization (unlike progestin only methods) which may delay administration
 - Progesterone-only methods:
 - Most effective when used within 72 hours of intercourse; treatment less likely to be effective up to 5 days
 - Levonorgestrel administered one time at a dose of 1.5 mg available by prescription and over the counter in the United States
 - Male patients should be educated about the use of EC and may purchase this method over the counter as well.
 - Yuzpe method of EC with COCs
 - Consists of 100 mcg EE + 0.5 mg levonorgestrel given with repeated 2nd dose 12 hours later
 - This method has higher rates of nausea and vomiting.
 - Generally used as a matter of urgent timing, convenience and expense if a woman has a COC pack of pills at home and prefers to use these for her EC method because the other methods are

more effective and have fewer side effects.

- Additional contraceptive methods:
 - General issues:
 - Well-known but with significantly lower efficacy
 - Include barrier methods to sperm entry (male and female condoms, diaphragms)
 - Male condoms
 - 88% effective with typical use; likely higher failure rates in adolescents
 - Female condom and diaphragm are 79% and 88% effective, respectively.
 - Proper condom use can prevent transmission of sexually transmitted infections such as HIV, HPV, HSV, syphilis, *Neisseria gonorrhoeae*, and *Chlamydia trachomatis*.
 - Important to inform teens that condoms are superior for STI prevention but inferior to other methods as a sole agent of contraception.
 - Spermicidal agents
 - Include: foam, film, vaginal inserts, as well as nonoxynal-9 as the active agent most widely used
 - Only 72% effective in preventing pregnancy with typical use. May reduce transmission of *C. trachomatis* and *N. gonorrhoeae*. When used with condoms, overall efficacy 93% with typical use
 - Irritant effect linked in some high-risk populations with increased risk of HIV transmission.
 - Spermicides must be inserted with each intercourse, near the time of intercourse; some formulations require 10–15 minutes for activation. Most have an unpleasant taste.
 - Progestin-only pills (POPs) (“mini-pill”)
 - Much less effective than most other hormonal methods, as effectiveness is highly dependent on perfect use
 - May offer some measure of benefit for women who are immediately postpartum (up to 6 months) and breastfeeding on demand
 - Typically not a good method for most teens

- Abstinence
 - Abstinence or refraining from vaginal-penile sexual intercourse is the most effective way to prevent unintended or unwanted pregnancy as well as transmission of STIs. However, gaining a mature understanding and experience of one’s gender and sexual development is a necessary and desired component of adolescent development.
 - Provider counseling and recommendations should promote a 4-pronged approach to sexual decision making: personal maturity and readiness, thoughtful partner selection and communication, family planning and pregnancy prevention, as well as prevention of STIs.

ALERT

- Advising teenagers to abstain from all forms of physical intimacy may be both unrealistic and counterproductive in the context of their psychosocial development.
- Providers should emphasize at every visit that only 100% use of condoms (or abstinence) protects against sexually transmitted diseases but is not the most effective form of birth control available.
- All forms of birth control are not “equal”—long acting reversible contraceptives are significantly more effective contraceptives than all other methods, even sterilization.
- Long acting reversible contraceptive implants are both highly desirable and well tolerated in adolescents and should be offered as first line contraceptives to teens.
- Include male patients in discussions about both condom use as well as contraceptive use.

GENERAL PREVENTION

- Encourage consistent use of latex condoms.
- Patients using oral contraceptive pills may be strongly encouraged to cease tobacco use, but tobacco use does not preclude EP methods in women younger than 35 years.

PATHOPHYSIOLOGY

- Combined EP hormonal therapy suppresses ovulation by directly

decreasing release of hypothalamic gonadotropin-releasing hormone (GnRH) and pituitary follicle-stimulating hormone (FSH) and luteinizing hormone (LH).

- Progesterone thickens cervical mucus, thins the endometrium, and decreases tubal motility. Higher dose systemic progestins inhibit the hypothalamic–ovarian axis and halt ovulation.
- Copper: Copper ions inhibit transtubal sperm migration and act in both an ovicidal and spermicidal way to prevent zygote formation.
- EC: Mechanisms of action include ovulation disruption, endometrial impairment to prevent implantation, and possibly sperm or ova transport alteration.
- Spermicides (nonoxynol-9 and octoxynol-9) destroy sperm cell membranes. Most spermicidal preparations contain an inert base (foam, cream, or jelly) to support the spermicidal agent and provide a barrier to sperm entry.

DIAGNOSIS

HISTORY

General considerations in family planning interviews and methods counseling:

- Open queries about family planning intentions should be included in all reproductive age anticipatory guidance or reproductive health visits.
- One Key Question, “Do you want to be pregnant in the next 6 months or year?” opens the conversation to all potential family planning intentions: intention to become pregnant, ambivalence about pregnancy, and desire for contraception and no immediate pregnancy plan.
- Method selection should consider and include the following: past use, failures, and side effects (both real and perceived) of contraceptives, priorities and goals for family planning.
- Does the patient want a pregnancy and parenting? Does his or her partner? Is the teen ambivalent about pregnancy and parenting?
- What is the teen’s sexual history? Ask about sexual debut, recent partners, lifetime number of partners, gender and risk behaviors of

partners, types of sexual behaviors (may be receptive or giving/insertive, penile-vaginal, penile-anal, oral, digital, dildos and other objects, other)

- Is sexual activity spontaneous or planned? Coerced or desired? Is the teen happy and confident about his or her sexual activity? Does sex give pleasure, feel uncomfortable, any other sexual concerns?
- What methods has the youth tried in the past? What worked, what did not work and why? Does the patient feel that she or he can be compliant with a daily pill or barrier methods? Can the teen demonstrate this ability with other medications or regimens?
- Does the patient require privacy and confidentiality? Does the teen have a parent or guardian's support regarding contraception and safer sex?
- Is the patient comfortable applying a condom or asking their partner to put on a condom?
- Does the patient have open communication with his or her partner? Does the partner respect the patient's decisions? Does the teen feel safe and respected by his or her partner?
- Are there any other barriers to adherence and continuation with the chosen contraceptive method? Is the patient comfortable with the level of efficacy and potential side effects with the current plan?

PHYSICAL EXAM

- Is not essential for some patients who need to start contraception on an urgent or emergency basis. A thorough medical history that excludes current pregnancy, medical conditions that would be a contraindication to particular methods, and a plan for follow-up can allow some providers to begin a method without a physical exam at that time.
- Exams may be helpful in obtaining baseline weight, BP, and other physical stigmata (hirsutism, acne) that may benefit from hormones.
- It is not necessary to perform a pelvic exam on asymptomatic young women initiating hormonal contraception. It is not recommended to perform a pelvic exam (bimanual and speculum) for an adolescent who has never been sexually active but requests contraception.
- A pelvic exam to assess and diagnose an STI or to evaluate for pregnancy in a patient with amenorrhea may be indicated.

- The Centers for Disease Control and Prevention (CDC) recommends screening for STIs after sexual debut and at least annually until age 25 years.
- Papanicolaou cancer screening begins after sexual debut and by 21 years of age. Pap guidelines have been evolving and changing over recent years.

DIAGNOSTIC TESTS & INTERPRETATION

- Pregnancy test prior to initiating hormonal contraceptives:
 - Urine pregnancy tests are typically adequate for diagnosing most pregnancies.
 - Serum human chorionadotropin hormone (B-hCG) is useful when trying to differentiate between normal and abnormal (miscarriage, ectopic) pregnancies.
- It is helpful to ask patients, “when was your last sexual activity without a condom and without birth control?” in order to determine the accuracy of your current pregnancy test, not exclude very early pregnancy, and create a follow-up plan for possible future pregnancy testing in 2–4 weeks.

TREATMENT

GENERAL MEASURES

- Barrier methods: Trained personnel can teach the proper technique for application of condoms and spermicidal agents.
- Fertility (and ovulatory cycles) should return within 6 months of the last DMPA injection.
- Etonogestrel implant is a simple procedure easily done in outpatient settings but requires training and certification by the manufacturer.
- IUDs are also simple outpatient procedures for primary care providers with pelvic and uterine exam skills. Insertion of an IUD should be scheduled when one can be as certain as possible that the adolescent is not pregnant but should not be delayed in a manner that places teen at risk for unintended pregnancy.
- All methods offer contraceptive protection immediately if inserted days

0–5 of their menstrual cycle. Most teens return to ovulation soon after discontinuation of most contraceptives.

ALERT

- Drugs that activate the cytochrome P-450 enzyme will diminish the efficacy of hormonal contraceptives and may include the following: phenobarbital, carbamazepine, primidone, rifampin, griseofulvin, HIV protease inhibitors, and tetracyclines (including doxycycline).
- Hormonal contraceptives can increase concentrations of phenytoin, benzodiazepines, antidepressants, corticosteroids, β -blockers, theophylline, and alcohol.
- Hormonal contraceptives can decrease the efficacy of acetaminophen, oral anticoagulants, hypoglycemics, and methyldopa.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Patients using hormonal contraceptives should be seen within 6 weeks to 2 months of initiation, to evaluate adherence, continuation and help manage side effects.
- BP, weight, and STIs may continue to be monitored.

PROGNOSIS

- Use of COCs declines over time:
 - 45% in 3 months
 - 33% at 1 year

COMPLICATIONS

Barrier methods

- Latex allergy: Patients may use polyurethane rather than latex condoms. Animal skin condoms are permeable to viral pathogens.
- Breakage or permeability: Oil-based lubricants and most intravaginal medications used with latex condoms will increase the risks of these complications.

Spermicides

- Local irritation or allergic reaction
- May increase the risk of HIV infection in adolescents with high-risk sexual partners

Hormonal EP contraceptives

- Contraindications to COC pills are uncommon in most teens and include the following: pregnancy, history of thromboembolic event, structural heart disease, breast cancer, active liver disease, migraine headaches with an aura, prolonged immobilization, or severe hypertension.
- Caution should be taken with women <6 weeks postpartum, with gallbladder disease, and those who use medications that affect liver enzymes.
- Minor, and usually self-limited, side effects of COCs may include intermenstrual spotting, nausea, breast changes, fluid retention, leukorrhea, minor headache, and depression.
- Thromboembolic events and liver disease are extremely rare in nonsmoking adolescents using estrogen-containing oral contraceptive pills. Placing risk in perspective is essential to adequate consent.

Estimates of VTE may be communicated as follows:

- Baseline risk: 10 in 100,000 women-years
- COC user risk: 15 in 100,000 women-years
- 3rd generation COC (desogestrel) or patch risk: 30 in 100,000 women-years
- Pregnancy risk: 60 in 100,000 women-years
- Mortality from estradiol-containing methods is estimated at 1 in 1.5 million per year. Mortality from bike riding, motor vehicle crashes, and other causes is much higher. Death from gynecologic and related causes was 7/100,000 in 15–19-year-old adolescents per year. If no fertility control measures were used, the mortality is 0.3/100,000 per year in nonsmoking oral contraceptive pill users and 2.2/100,000 per year in smoking oral contraceptive pill users.

Progestin-only methods

- POPs' side effects include weight gain, rapid hair turnover, and menstrual irregularities.
- DMPA can reduce bone mineral density (BMD), which typically

rebounds to normal after DMPA discontinuation. Because adolescence is the period of peak bone mass accretion, there is concern that DMPA use during adolescence may increase the risk for osteopenia or osteoporosis later in life. This has not been proven or validated at present. For adolescents with anorexia nervosa, chronic steroid use, chronic renal failure, there may be better LARCs available that have no BMD impact.

- Most common side effect reported with etonogestrel implant is abnormal bleeding. A wide range of bleeding patterns may be experienced, and it is not possible to predict the bleeding pattern for any individual.
- Overall, in the 90-day reference periods of clinical trial experience, 33.3% had infrequent bleeding, 21.4% had amenorrhea, 6.1% had frequent bleeding, and 16.9% had prolonged bleeding.
- The lower androgenic effect of etonogestrel may make side effects of acne and weight gain less frequent than with other progestins.

IUDs

- Contraindications to IUD placement are those who are pregnant or suspected to be pregnant, have active PID or puerperal or postabortion sepsis, malignancy of the genital tract, uterine abnormalities that distort the uterine cavity, an allergy to any component of IUDs, or Wilson disease (for the copper T IUD only).
- IUDs have been associated with a slightly higher risk of PID within the first 21 days after insertion, especially if cervical infection is present. IUDs do not increase risk of PID above baseline after this time.
- Younger age may confer an increased risk of IUD failure from expulsion because of smaller uterus and higher incidence of nulliparity.
- The copper T IUD has been associated with increased menstrual bleeding and spotting, especially in first 3–6 months after insertion. In addition, some women may experience menstrual pain and heavy bleeding throughout use.

Emergency contraception

- Nausea and/or vomiting occur in most patients using Yuzpe (EP) EC or “doubling up” on oral contraceptive pills.

- Z30.09 Encounter for oth general cnsl and advice on contraception
- Z30.8 Encounter for other contraceptive management

FAQ

- Q: My adolescent, minor patient asks for confidentiality regarding contraception. Can I comply?
- A: Yes. Teenagers benefit from private and confidential contraceptive services. Teens should have right to confidentiality regarding contraception and treatment of STIs, even though some states do not have specific laws protecting these rights. The benchmark of care supported by all professional medical societies supports private and confidential contraceptive care for teens. Do not assume, however, that a teen may not have or benefit from parental support in her efforts to prevent pregnancy. It may be in the patient's best interest to have a caring adult involved. Which adult and how he or she is involved should be negotiated with the adolescent.
- Q: My adolescent patient has been on and off short-acting birth control methods? I am worried about her risk of pregnancy? How might I better help her?
- A: There are several parts to managing this issue.
 - First, in an open and supportive manner, ask her whether she wants to become pregnant and parent or would she like to delay pregnancy?
 - Second, if she wishes to delay pregnancy over the next 6–12 months, offer her a LARC. Educate her on the superior efficacy and ease of use. Insert a LARC that day or facilitate an urgent referral to a teen-friendly provider if she continues to express an interest.
 - While she waits for that appointment, offer to help her protect from unintended pregnancy with a single dose of DMPA providing coverage for the next 12 weeks. Offer her EC as well.
 - Applaud efforts to be smart and safely sexually active.
 - Engage her partner, if present and supportive, in contraceptive discussions and discussions about safe, satisfying, and responsible sexuality.
- Q: One of my patients has asked me to prescribe EC in advance for her. Is this something that I should do?
- A: Yes! EC is now over the counter, but if a patient is more likely to access using insurance coverage, this may increase use. Studies done clearly show that use of EC is safe. In fact, there are no absolute

contraindications to using progestin-only EC. Because unprotected sexual encounters often take place at a time when adolescents do not have access to their health care providers (e.g., evenings or weekends), advanced prescription may be of benefit for many adolescents.

- Q: What should I tell my patient if she misses a dose of her oral contraceptive?
- A: If she has missed 1 pill, she should take it as soon as she remembers, then take the next pill at the regular time. If she has missed 2 doses, she should take 2 when she remembers, and then 2 the next day. She should use a back-up method during the cycle in which she had to “double up.” If she has missed 3 or more pills, she will probably menstruate. After discarding the last pack, she should start a new pack on the 1st Sunday after the start of her next period. She is not protected during the remainder of this cycle.

COR PULMONALE

Brian D. Hanna • Heather L. Meluskey

BASICS

DESCRIPTION

- Cor pulmonale is right ventricular (RV) failure secondary to an altered pulmonary process that results in a loss of functional capillary vascular bed and in excessive pulmonary artery pressure and pulmonary vascular resistance (PVR).
- Cor pulmonale is not the result of a primary congenital heart defect.

ALERT

- In newborns, the RV muscle mass is comparable to that of the left ventricle.
- RV failure from pulmonary hypertension (PH) occurs but is rare in newborns.
- RV failure in newborns is usually a consequence of hypoxemia, ischemia, metabolic acidosis (e.g., persistent fetal circulation), and/or premature restriction/closure of the intrauterine ductus arteriosus.

EPIDEMIOLOGY

- Cor pulmonale may be found at any age but is typically a result of a long-standing pulmonary process. However, severe bronchopulmonary dysplasia is an increasingly common cause of neonatal PH.
- Primary pulmonary hypertension (PPHN) is most often diagnosed in the 2nd or 3rd decade of life with a female predominance, and it is often diagnosed during pregnancy.

Incidence

- PPHN has an annual incidence of 2 per million.

Prevalence

- Upward of 2 per 1,000 neonatal intensive care unit patients will develop significant cor pulmonale.
- 2% of infants undergoing cardiac surgery will have PH, with an

associated mortality of 10–20%.

RISK FACTORS

Genetics

- Pediatric patients with trisomy syndromes are at high risk for PH.
- Familial PH has been mapped to chromosome 2q32, but this is less frequently found in patients with secondary etiologies of PH.
- Region 2q32 point mutations encode for a defective bone morphogenic receptor 2, a pulmonary vascular smooth muscle receptor that mediates proliferation.

PATHOPHYSIOLOGY

- Chronic hypoxia is the principal factor, resulting in a cascade of endothelial dysfunction with pulmonary vasoconstriction, followed by the development of PH.
- A variety of vasoactive mediators may be responsible for the effect on vasomotor tone.
- Alveolar hypoventilation, hypoxemia, hypercarbia, and/or acidemia all result in increased RV afterload and decreased RV systolic function.

ETIOLOGY

- Parenchymal lung disease (most common)
- Chronic obstructive pulmonary disease
 - Cystic fibrosis
 - Asthma
- Restrictive lung disease
 - Infectious
 - Pulmonary toxins
 - Pulmonary fibrosis
 - Bronchopulmonary dysplasia (combined)
- Upper airway diseases: tonsillar/adenoidal hypertrophy
- Syndromes (Down, Treacher Collins)
- Neuromuscular disorders: Duchenne muscular dystrophy
- Chest wall deformities

COMMONLY ASSOCIATED CONDITIONS

- Pulmonary vascular abnormalities

- Collagen vascular diseases
- Pulmonary veno-occlusive disease
- Pulmonary thromboembolism
- PPHN

DIAGNOSIS

HISTORY

- Fatigue
- Failure to thrive/weight loss
- Dizziness
- Syncope
- Exercise intolerance
- Chest pain (secondary to RV ischemia)
- Palpitations
- Hemoptysis

ALERT

Hemoptysis is a life-threatening emergency and heralds a poor prognosis for any patient with PH.

PHYSICAL EXAM

- Tachycardia
- Parasternal RV impulse
- Cyanosis may be evident.
- Hepatomegaly, jugular venous distention, peripheral edema
- A loud, narrowly split or single 2nd heart sound (P_2); RV gallop; holosystolic murmur right of the sternum (tricuspid regurgitation); and/or diastolic murmur at the left upper sternal border (pulmonary insufficiency)

ALERT

In the newborn period to puberty, an abnormally increased RV impulse is best felt under the xiphoid sternum.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Brain-type natriuretic peptide is an excellent biomarker of RV diastolic dysfunction and is elevated with worsening cor pulmonale.
- Decreased PaO₂, increased PaCO₂, and a compensatory metabolic alkalosis
- Polycythemia may be consistent with chronic hypoxemia.

Imaging

- Chest radiograph: cardiomegaly from RV dilation and main pulmonary artery enlargement
- Echo: RV dilation, tricuspid annular plane systolic excursion (TAPSE), RV hypertrophy, pulmonic insufficiency, RV pressure estimate from tricuspid regurgitation, and/or intraventricular septal position
- Ventricular/perfusion (V/Q) scan is beneficial to rule out thromboembolic disease.
- Chest CT scan: volumes to assess lung hypoplasia, interstitial lung disease, thromboembolic disease, and large pulmonary vein disease

Diagnostic Procedures/Other

- ECG: may show right atrial enlargement, RV hypertrophy, and T-wave inversion
- 6-minute walk: measures functional capacity and limitations; 2 minute tests are reliable for those younger than 6 years old.
- Cardiac catheterization, although invasive, remains the gold standard.
- Lung biopsy is usually contraindicated in the face of PH and significant lung disease.

Pathologic Findings

- Vascular lesions (plexiform lesions)
- Parenchymal fibrotic lesions
- Concentric and eccentric remodeling

DIFFERENTIAL DIAGNOSIS

- Congenital heart disease with PH and right-to-left shunt (Eisenmenger syndrome)
- Obstruction of pulmonary venous return, both anatomic obstruction and left ventricular failure
- Pulmonary veno-occlusive disease
- Alveolar capillary dysplasia

TREATMENT

MEDICATION

First Line

- Oxygen to keep saturations >90%
- Anticongestive medications (digoxin, diuretics)

Second Line

Vasodilator therapy with care not to worsen the intrapulmonary shunt

ADDITIONAL TREATMENT

General Measures

- The primary goal is reduction of the abnormally elevated pulmonary artery pressure and the RV workload.
- If at all possible, address the primary etiology (i.e., tonsillectomy/adenoidectomy in a patient with obstructive upper airway disease).
- Fluid boluses are poorly tolerated and rarely augment systemic BP.
- Oxygen (nocturnal oxygen)
- Diuretics (if pulmonary congestion)
- Bronchodilators (theophylline)
- Digoxin (may improve RV contractility)
- Anticoagulants
- Pulmonary vasodilators
 - Nitric oxide
 - Calcium channel blockers (only if >1 year of age and cardiac output is not compromised)
 - Phosphodiesterase-5 inhibitors
 - Endothelin receptor antagonists
 - Prostanoid
- Atrial septostomy (in select cases, may improve cardiac output but at the expense of hypoxemia)
- Lung or heart–lung transplantation
- Usually self-limited activity
- No competitive sports

- Arginine, a nitric oxide donor, has been used; however, the increased amino acid concentrations are proliferative and may worsen the long-term prognosis.

SURGERY/OTHER PROCEDURES

Consider tracheostomy, Nissen fundoplication, and gastrostomy tube (G-tube) early

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

Home oxygen saturation monitoring is indicated when night oxygen is necessary to keep saturations >90%.

PROGNOSIS

- Patients with reversible lung disease usually have a better prognosis.
- Patients with cor pulmonale are at risk for sudden death because of the inability to augment cardiac output with exercise, growth, or febrile illnesses.
- Numerous medical therapies and lung transplantation may improve long-term survival.
- Long-term survival is variable and depends on the age at onset of pulmonary changes and the underlying conditions (e.g., Down syndrome) that may adversely affect survival.
- Death often occurs in the 2nd or 3rd decade of life.

COMPLICATIONS

Aside from the underlying lung process, the chronic hypoxia results in polycythemia, decreased systemic oxygen delivery, and RV failure secondary to the inability of the RV to handle the excessive afterload.

CODES

ICD10

- I27.81 Cor pulmonale (chronic)
- I26.09 Other pulmonary embolism with acute cor pulmonale

FAQ

- Q: Is cardiac catheterization indicated in all patients with cor pulmonale?
- A: Yes. Although a great deal of information can be learned from echocardiogram, direct pulmonary artery pressure/resistance measurements require an invasive procedure. In addition, assessment of the reactivity of the pulmonary vascular bed to various agents

(oxygen, prostacyclin, and calcium channel blockers) is best performed in the catheterization laboratory.

- Q: Is nocturnal oxygen therapy beneficial?
- A: Nocturnal oxygen has been speculated to delay the progression of cor pulmonale in some select patients with obstructive sleep hypoxemia.

COSTOCHONDRITIS

Richard M. Kravitz

BASICS

DESCRIPTION

Costochondritis is chest pain that emanates from a costal cartilage and is reproducible on compression of that cartilage.

EPIDEMIOLOGY

- Frequency of sternal wound infections following median sternotomy is 0.1–1.6%.
- Costochondritis accounts for 10–31% of all pediatric chest pain.
- Peak age for chest pain in children is 12–14 years.

PATHOPHYSIOLOGY

- Inflammation of unknown etiology (histologic examination is usually normal)
- Infection
 - Can present months to years after surgery (the costal cartilage is avascular, making it vulnerable to infection if it has been exposed, injured, or denuded of perichondrium)
 - Complication of median sternotomy
 - Occurs by spread from adjacent osteomyelitis or may arise de novo during surgery

ETIOLOGY

- Infectious
 - Bacterial
 - *Staphylococcus aureus* (especially after thoracic surgery)
 - *Salmonella* (in sickle cell disease)
 - *Escherichia coli*
 - *Pseudomonas* sp.
 - *Klebsiella* sp.
 - Fungal

- Aspergillus flavus
 - Candida albicans
- Posttraumatic injury

DIAGNOSIS

HISTORY

- Inflammatory costochondritis
 - Pain usually preceded by exercise or an upper respiratory tract infection
 - Description of pain
 - Usually sharp
 - Affects the anterior chest wall
 - Localized or radiates to the back or abdomen
 - Usually unilateral (left side greater than right side)
 - The 4th–6th costochondral junction is the usual site of pain.
 - Motion of the arm and shoulder on the affected side elicits the pain.
 - Girls are affected more often than are boys.
- Tietze syndrome
 - Onset is usually abrupt but can be gradual.
 - Believed to be caused by a minor trauma, although etiology is unknown
 - Description of pain
 - Radiates to arms or shoulder
 - May last up to several weeks
 - Swelling at the sternochondral junction may persist for several months to years.
 - Usually affects the 2nd or 3rd costochondral joint
 - Pain is aggravated by sneezing, coughing, deep inspiration, or twisting motions of the chest.
 - No differences in frequency between sexes
- Infectious costochondritis
 - Slow, insidious course
 - Usually unimpressive clinical symptomatology

PHYSICAL EXAM

- Usually normal
- Inspect for evidence of trauma, scars, bruising, and swelling.
- Palpation and percussion of the costochondral and costosternal junctions should reproduce and localize the pain.
- In Tietze syndrome, spindle-shaped swelling is visible at the sternochondral junction.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- WBC count not helpful (even when infection present)
- EKG (may be helpful if cardiac etiology is being considered)

Imaging

- Radiologic studies (chest x-ray, CT) usually not helpful
- Gallium scan
 - May be useful in some cases of infectious origin
 - Not highly specific
 - May show increased radionuclide uptake
 - No evidence of osteomyelitis of the sternum in most cases
- Technetium bone scan
 - Not highly specific

DIFFERENTIAL DIAGNOSIS

- Cardiovascular
 - Myocardial infarction
 - Pericarditis
 - Pericardial effusion
 - Myocarditis
 - Endocarditis
 - Cardiomyopathy
 - Premature ventricular contractions
 - Supraventricular tachycardia
 - Dissecting aneurysm
- Pulmonary
 - Asthma
 - Exercise-induced bronchospasm

- Pneumonia
- Pleural effusion
- Pneumothorax
- Pulmonary embolism
- GI
 - Gastroesophageal reflux
 - Esophagitis
 - Gastritis
 - Achalasia
- Mechanical
 - Muscle strain
 - Stress fractures
 - Precordial catch syndrome
 - Trauma
- Rheumatologic
 - Rheumatoid arthritis
 - Ankylosing spondylitis
- Oncologic
 - Rhabdomyosarcoma
 - Leukemia
 - Ewing sarcoma
- Miscellaneous
 - Tietze syndrome
 - Psychogenic chest pain
 - Breast tissue pain (both sexes)

TREATMENT

GENERAL MEASURES

- Inflammatory costochondritis
 - Anti-inflammatory and analgesic agents
 - Reassurance
 - If pain disturbs normal activities and sports, infiltration with local anesthetic may prove useful.

ALERT

- Inflammatory costochondritis
 - Important cause of school absence
 - Adolescents tend to limit physical activity unnecessarily for long periods.
 - Restriction of activities is usually not required.
 - Most adolescents still worry about cardiac problems, even after the diagnosis has been made.
- Infectious costochondritis
 - Prolonged course of intravenous (IV) antibiotics
 - Prompt surgical resection of all involved cartilage
 - Reconstructive surgery with muscular flaps should be done.

ALERT

- Infectious costochondritis
 - Long-term IV antibiotics alone do not resolve the problem; surgical resection and repair also are required.
 - There is a tendency for the infection to spread to adjacent costal cartilages and across the sternum to the contralateral chest wall.
 - In general, avoid costochondral junctions when performing surgical procedures in the chest (i.e., chest tube placement).

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Inflammatory costochondritis
 - Long-lasting condition
 - Follow-up once a year is recommended.
- Infectious costochondritis
 - Long-term follow-up after surgery is mandatory.

PROGNOSIS

- Inflammatory costochondritis: excellent
- Infectious costochondritis: prognosis relates to

- Underlying clinical condition of the patient (i.e., immunocompromised, postradiation therapy for cancer, postcardiac surgery)
- Extent of surgery required to reconstruct the area damaged by the infection

CODES

ICD10

M94.0 Chondrocostal junction syndrome [Tietze]

FAQ

- Q: Am I having or will I have a heart attack?
- A: Chest pain does not imply a heart problem. This pain arises from the chest wall; there is no risk of a myocardial infarction. A cardiac etiology to chest pain in an adolescent is usually uncommon.
- Q: Is costochondritis related to arthritis?
- A: There is no relation to any form of arthritis.
- Q: Where does the name Tietze syndrome come from?

- A: The syndrome is named after German surgeon Alexander Tietze (1864–1927), who first described the syndrome in 1921.

COUGH

Margaret M. McNamara • Gwynne D. Church

BASICS

DESCRIPTION

A high-velocity expulsion of gas from the airways that serves to clear them of mucus, cellular and microbial debris, or foreign bodies. An absence or inability to cough can lead to recurrent pneumonia. Cough can be acute (<2 weeks), subacute/protracted (2–4 weeks), or chronic (>4 weeks).

EPIDEMIOLOGY

Cough is the most common symptom presenting to primary care physicians in the United States and worldwide. Chronic cough accounts for up to 9% of chief complaints to U.S. pediatricians.

Healthy children can have a nonpathologic cough. School-age children typically experience 10 cough episodes per day.

PATHOPHYSIOLOGY

Cough results from a complex reflex phenomenon initiated by cough receptors that is mediated through the brainstem. The receptors are located in the respiratory tract from the larynx to the segmental bronchi, paranasal sinuses, external auditory canal, and stomach and are triggered by thermal, chemical, mechanical, or inflammatory stimuli. Cough is generally reflexive but may sometimes be voluntarily initiated or suppressed.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Infection and asthma are the most common causes of cough in all pediatric age groups and should always be considered.

Children have an average of 6–8 upper respiratory infections (URIs) per year, with each lasting up to 2–3 weeks. Roughly 1/3 of preschool-aged children cough more than 10 days after a cold, and 10% of preschool children cough more than 25 days after a cold.

- **Causes of acute (<2 weeks) or subacute/protracted (2–4 weeks) cough**
 - Infection
 - Reactive airway disease (RAD)
 - Sinusitis
 - Irritants
 - Allergy
 - Foreign body
- **Causes of chronic (>4 weeks) cough**
 - Bronchitis
 - Postinfectious
 - Sinusitis
 - Asthma
 - Irritants (cigarette smoke exposure, air pollution)
 - Allergic rhinitis
 - Foreign body
 - Gastroesophageal reflux (GER)
 - Habitual or psychogenic
 - Anatomic abnormalities: tracheoesophageal fistula, tracheobronchomalacia, laryngeal cleft, polyps, adductor vocal cord paralysis, pulmonary sequestration, bronchogenic cyst, cystic hygroma, vascular ring, tumor
 - Cystic fibrosis (CF)
 - Ciliary dyskinesia
 - Immunodeficiency states that result in recurrent respiratory infections: HIV, immunoglobulin deficiencies (IgA, IgG), phagocytic defects, complement deficiency
 - Interstitial lung disease
 - Angiotensin-converting enzyme inhibitors
 - Stimulation of external auditory canal cough receptors (Arnold reflex cough)

APPROACH TO PATIENT

Given the common nature of cough and the large differential diagnosis it generates, an extremely thorough history and physical exam (H&P) should direct a rational, stepwise approach.

HISTORY

- **Question:** How long has the child coughed?
- **Significance:** Most acute and subacute coughs are associated with viral URIs. Pediatric chronic cough is defined as daily cough that lasts for >4 weeks.
- **Question:** Is there a recent history of URI?
- **Significance:** Serial URIs, the most common cause of chronic cough in children, can be diagnosed by a careful history of waxing and waning symptoms and will avoid unnecessary tests. Also consider postinfectious cough (due to heightened cough receptor sensitivity) or sinusitis (which complicates up to 5% of URIs). Overall, 8–12% of children with URIs develop complications.
- **Question:** What are the associated symptoms?
- **Significance:**
 - Fever and nasal discharge suggests infection.
 - Fever with chills or night sweats suggests TB in children with chronic cough.
 - With rhinorrhea, halitosis, headache, or facial edema, consider sinusitis.
 - With respiratory distress, suspect RAD, infection, or foreign body.
- **Question:** What is the quality of the cough?
- **Significance:**
 - Acute wet cough suggests upper or lower airway respiratory infection or asthma.
 - Subacute wet cough suggests sinusitis, bronchitis, or asthma.
 - Chronic wet cough is always abnormal and can be associated with sinusitis, bronchitis, asthma, CF, ciliary dyskinesia, bronchitis, or anatomic lower airway abnormality such as tracheomalacia.
 - Dry cough can suggest asthma.
 - Barking cough is usually associated with croup.
 - Brassy cough is associated with tracheomalacia.
 - A honking or barking chronic cough that increases during times of stress and is absent during sleep is typical for habit cough.
 - Staccato cough suggests chlamydial pneumonia in infants.
 - Paroxysmal cough, with or without whoop, suggests pertussis or

parapertussis.

- **Question:** What is the pattern of the cough?
- **Significance:**
 - Chronic nighttime cough suggests RAD, postnasal drip from allergic rhinitis, or GERD.
 - With nighttime/early morning cough, consider sinusitis or allergic rhinitis.
 - Seasonal cough suggests allergy.
- **Question:** Are there any known triggers of cough (e.g., smoke, cold air, dust, URI)?
- **Significance:** Consider irritant, allergy, or RAD.
- **Question:** Is there any personal or familial history of atopy?
- **Significance:** Consider RAD.
- **Question:** Are there recurrent infections?
- **Significance:** Consider immunodeficiency, CF. Consider pulmonary sequestration if patient has recurrent pneumonias in same location.
- **Question:** Is there any relation of cough to feedings?
- **Significance:** Consider aspiration, GER, laryngeal cleft, and tracheoesophageal fistula.
- **Question:** Is there a history of a choking episode?
- **Significance:** Consider retained foreign body.
- **Question:** Is there exercise intolerance?
- **Significance:** Consider asthma, interstitial lung disease
- **Question:** What is the parental level of concern?
- **Significance:** Children's cough generates significant parental stress and concerns, and appreciation of parental worries is valuable when addressing this problem.

PHYSICAL EXAM

Assess patient's general appearance

- **Finding:** Evidence of failure to thrive?
- **Significance:** Consider TB, CF, immunodeficiency, aspiration
- **Finding:** Cyanosis or pallor?
- **Significance:** Consider pneumonia, asthma
- **Finding:** Signs of respiratory distress such as tachypnea, accessory muscle use?

- Significance: Consider pneumonia, asthma, congenital anatomic abnormalities
- **Finding:** Barrel chest?
- Significance: Suggests air trapping due to chronic disease
- **Finding:** Clubbing?
- Significance: Consider CF, ciliary dyskinesia, interstitial lung disease, chronic aspiration
- **Finding:** Nasal polyp?
- Significance: Must rule out CF. Also seen with allergic rhinitis.
- **Finding:** Tracheal deviation?
- Significance: Suggests mediastinal mass or foreign body aspiration
- **Finding:** Signs of atopic disease such as eczema, allergic shiners, transverse nasal crease, rhinitis, mucosal cobblestoning, injected conjunctivae?
- Significance: Allergic rhinitis
- **Finding:** Rhinorrhea/purulent posterior pharyngeal drainage, sniffing, halitosis, periorbital edema, sinus tenderness?
- Significance: Suggest sinusitis
- **Finding:** Crackles (rales)?
- Significance: Coarse crackles suggest bronchiectasis; fine crackles suggest pneumonia, atelectasis, pulmonary edema, and interstitial lung disease.
- **Finding:** Rhonchi
- Significance: Bronchitis, impaired cough (from weakness, tracheostomy)
- **Finding:** Decreased breath sounds
- Significance: Suggests pneumonia, pleural effusion, chest mass
- **Finding:** Wheezing?
- Significance:
 - Polyphonic inspiratory or expiratory wheezes suggest RAD.
 - Monophonic or fixed wheezes should make one consider foreign body or mass/congenital lesion.

DIAGNOSTIC TESTS & INTERPRETATION

- Laboratory investigation should reflect a rational, stepwise approach based on likely etiologies after a thorough history.

- Evidence-based clinical practice guidelines for evaluating chronic cough in pediatrics were published in 2006. In general, children with chronic cough should have a chest radiograph, and spirometry should be considered for children >4 years of age.
- **Test:** chest x-ray posteroanterior/lateral
- Significance: Detect infection, foreign body, chronic aspiration, interstitial lung disease, pulmonary edema, diaphragmatic hernia, signs typical for asthma, CF
- **Test:** Spirometry
- Significance: Detect airway obstruction or lung restriction. Pre- and post-bronchodilator response is useful to diagnose asthma.
- **Test:** Microbiology workup as indicated (e.g., polymerase chain reaction [PCR] for pertussis, direct fluorescent antibody [DFA] for viral panel, culture for Chlamydia)
- Significance: Aids in precise diagnosis and treatment as needed
- **Test:** Paranasal sinus CTscan
- Significance: Should be used judiciously to evaluate sinus disease, that is, for complications of sinusitis, recurrent sinusitis
- **Test:** CBC
- Significance: Eosinophilia suggests atopic disease or, rarely, parasitic infection; anemia should prompt one to consider chronic disease or, rarely, pulmonary hemosiderosis; leukocytosis suggests infection.
- **Test:** Bronchoscopy
- Significance: Diagnose presence of foreign body, and airway anomalies (laryngeal cleft, tracheobronchomalacia, tracheoesophageal fistula [TEF], vascular ring) and perform alveolar lavage for cultures, cytology, hemosiderin-laden macrophages (suggests alveolar bleeding), lipid-laden macrophages (suggest aspiration)
- **Test:** Barium swallow
- Significance: Aspiration
- **Test:** Upper GI series
- Significance: Vascular ring
- **Test:** Mantoux test: purified protein derivative (PPD) skin test
- Significance: To diagnose TB
- **Test:** Serum IgE

- Significance: Significant elevation indicates allergy or, rarely, allergic bronchopulmonary aspergillosis
- **Test:** Sweat test
- Significance: To diagnose CF, but need to be sure that laboratory has experience with this test
- **Test:** Immune workup
- Significance: HIV, immunodeficiency
- **Test:** pH probe
- Significance: GER
- **Test:** High-resolution CT scan of the thorax, video fluoroscopy, echocardiogram, or nuclear medicine scans
- Significance: May be judiciously used; generally reserved until after referral to a specialist

Imaging

Chest x-ray

- Infiltrates may suggest pneumonia, bronchiolitis, pneumonitis, TB, CF, bronchiectasis, or foreign body.
- Volume loss may be seen with foreign body aspiration; sometimes need to obtain lateral decubitus views in young children who cannot cooperate with inspiratory/expiratory views.
- Hyperinflation suggests RAD or CF.
- Mediastinal nodes may indicate infection (especially TB or fungal) or malignancy.

TREATMENT

ADDITIONAL TREATMENT

General Measures

- Cough should be treated based on etiology.
- OTC cough medicines are widely prescribed and overused.
- The U.S. Food and Drug administration (FDA) and Consumer Healthcare Products Association recommend avoiding OTC cough and cold medicines in children <4 years of age. An American Academy Pediatrics position statement questions the efficacy and safety of these

medications in children <6 years of age.

- To avoid overuse of antibiotics, parents should be informed that viral URI can cause cough that commonly lasts up to 2–3 weeks.
- Educate parents about the beneficial function of cough to remove irritants and about the potential harm of suppressing a productive cough or cough secondary to RAD.
- Honey may be used in children older than age 1 year. Acute cough from URI or chronic nonspecific cough (i.e., dry cough in the absence of asthma or other identifiable disease) may be safely, effectively, and inexpensively treated with honey.
- Specific pharmacologic interventions:
 - RAD: Bronchodilators ± inhaled anti-inflammatory agents, oral or inhaled steroids, removal of irritants
 - Infection: Appropriate antibiotics as indicated. May be considered in cases of chronic productive cough or pneumonia.
 - Antihistamines (nonsedating) should be used only when cough coexists with rhinitis.
- Self-hypnosis is a safe, effective treatment for children with habit cough.
- Children with “nonspecific cough” (i.e., without specific indicators by H&P as noted earlier) generally do not derive much benefit from medications and may undergo a period of “watchful waiting.” If medications are used, patients need to be reassessed in 2–3 weeks.

ISSUES FOR REFERRAL

- The vast majority of cases of cough, even when chronic, can be diagnosed and managed by the primary care physician.
- Factors in making a referral:
 - The cough is unresponsive to treatment.
 - The cause is likely to be an anatomic malformation or foreign body aspiration.
 - There appears to be involvement of other organ systems (e.g., failure to thrive, CF, congestive heart failure, immunodeficiency, unusual infection).
- Hemoptysis

Initial Stabilization

- Cough should be considered an emergency if there are associated signs or symptoms of respiratory distress.
- Routine emergency airway assessment should be undertaken on presentation and appropriate supportive measures started in cases in which there is concern.

- J45.909 Unspecified asthma, uncomplicated

FAQ

- Q: Is whooping cough still a problem despite routine childhood immunization?
- A: Yes. Pertussis often goes unrecognized as a cause of acute and chronic cough, particularly in infants who have not completed their immunization series and in older children, adolescents, and adults. Immunity from vaccination or natural infection may wane within 5 years, thus providing a reservoir of pertussis in the community. Tdap vaccination is recommended for all 11 years of age and older.
- Q: How can an ear examination help explain the cause of chronic cough?
- A: For some patients, the presence of cerumen, a foreign body, or irritation of the external auditory ear canal can stimulate the auricular branch of the vagus nerve (“Arnold nerve”) and trigger a cough. This is also known as the oto-respiratory reflex. One study conducted in India suggests a 4% prevalence of this phenomenon.

CROHN DISEASE

Helen Pappa

BASICS

DESCRIPTION

Crohn disease (CD) is a chronic inflammatory bowel disease (IBD) affecting any part of the gastrointestinal (GI) tract from the mouth to the anus. Crohn disease is generally characterized by transmural skip lesions, as well as periods of exacerbations and quiescence.

EPIDEMIOLOGY

- ~20–25% of patients are diagnosed with CD in childhood or adolescence.
- Family history is present in 30% of patients <30 years old.
- In adulthood, male = female; in childhood, male > female (1.6:1)
- Highest frequency in Caucasian populations; however, CD can be diagnosed in patients of all racial backgrounds.

RISK FACTORS

Genetics

- 1st-degree relatives have a 5–25% higher risk of developing CD than the normal population.
- Children of 1 parent with CD have a 7–16% risk of developing either CD or ulcerative colitis.
- Siblings of patients with IBD are at 30 times higher risk of developing the disease.
- Concordance in monozygotic twins is 50%; in dizygotic twins, 38%
- CD is complex genetic disease:
 - Over 100 gene loci have been associated with CD.
 - Gene mutations in CD involve pathways responsible for microbe recognition and autophagy.
 - The first gene association was with NOD2/CARD15, a protein important in innate immunity.
 - CARD15 mutation is present in ~14–18% of patients. Homozygotes

carry 2–4% lifetime risk of developing CD.

- Additional genetic links found to possibly predict responses to corticosteroids, anti-TNF agents.

PATHOPHYSIOLOGY

- Interaction and combination of environmental factors, genetic susceptibility, host's intestinal microbiota, and a yet, unspecified triggering factor (likely bacterial products) lead to a dysregulated immune response, causing chronic intestinal inflammation.
- CD pathogenesis is now attributed to dysfunction of both innate and adaptive immunity.
 - Innate immunity: Defects have been identified in epithelial barrier, microbial sensing, and autophagy in CD, for example, patients with the CARD15/NOD2 mutation have dysregulated response to bacterial products.
 - Adaptive immunity: abnormal activation of T-helper-1 and Th17 lymphocytes leads to overproduction of inflammatory cytokines such as IL-2, interferon γ , IL-6, TNF- α , and IL-17 which cause invasive intestinal inflammation in CD.
- IL-23 is a significant cytokine in CD. Polymorphisms in the IL-23R gene have been associated with aberrant responses of both the innate and adaptive immune systems. In the GI tract, release of inflammatory cytokines causes transmural inflammation with cryptitis, crypt abscesses and distortion of crypt architecture, and pathognomonic formations called granulomas (in 20–40% of biopsies).
- Macroscopically, the following are characteristics of CD:
 - Ulcerations
 - “Creeping fat” (increased mesenteric fat surrounding inflamed small intestinal loops)
 - Sinus tracts (extension of deep ulcerations beyond the intestinal wall)
 - Fistulae (communications between intestine and skin, other intestinal loops or other organs)
 - Strictures
- The most common site to be affected in the GI tract is the terminal ileum. Other sites most often affected, in decreasing frequency, are

right colon, isolated colon, proximal small bowel, and upper GI tract (i.e., stomach, duodenum, esophagus).

DIAGNOSIS

HISTORY

- Diarrhea (80%)
- Weight loss (85%)
- Abdominal pain (85%)
- Rectal bleeding (50%)
- Fever (40%)
- Growth failure (35%)
- Perianal disease (25%)
- Nausea and vomiting (25%)
- Delayed puberty
- Menstrual irregularity
- Extraintestinal disease (25%)
 - Arthritis
 - Erythema nodosum
 - Pyoderma gangrenosum
 - Mouth ulcers
 - Episcleritis
 - Uveitis
 - Thromboembolic disease
 - Vasculitis
 - Renal stones
 - Amyloidosis
 - Sclerosing cholangitis
 - Pancreatitis
- Other history could include the following:
 - Enteric infection (including *Clostridium difficile*)

PHYSICAL EXAM

- Growth delay and weight loss, delayed puberty
- Abdominal examination:

- Hyperactive bowel sounds
- Right lower quadrant (RLQ) mass and tenderness
- Palpable thickened loop of intestine
- Rectal and perianal examination: skin tag, fissure, fistula, and abscess

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- CBC; common to see microcytic anemia (due to iron deficiency); can also see a normocytic anemia due to chronic disease or a macrocytosis (suggesting nutrient deficiency, especially iron, B₁₂, folate, zinc)
- Elevated ESR, C-reactive protein, stool calprotectin (disease activity)
- Electrolytes (reflect hydration, renal function)
- Transaminases, alkaline phosphatase, γ -glutamyl transpeptidase (hepatobiliary disease)
- Stool for occult blood and presence of white cells
- Stool cultures, Clostridium difficile toxin A and B
- Serologic profiles, including perinuclear antineutrophil cytoplasmic antibody (pANCA) and anti Saccharomyces cerevisiae antibody (ASCA), may be helpful in differentiating among types of IBD.
- Genetic screening among healthy, asymptomatic patients is not recommended.

Imaging

- Consider plain abdominal x-ray in acute presentation to rule out obstruction or perforation.
- MRI enterography to assess disease extent and activity is radiation-sparing and provides information about small bowel and colonic disease, including abscesses and fistula.
- Barium upper GI and small bowel follow-through may also be used to evaluate extent of disease in small bowel not accessible to endoscopy—involves exposure to radiation.
- CT scan and ultrasound may be necessary to evaluate complications (abscess, phlegmon).
- Colonoscopy and upper endoscopy with multiple biopsies are the gold standard tests for initial evaluation and diagnosis of CD.
- Video capsule endoscopy can be used to access small bowel not

visualized at the time of endoscopy.

- Balloon-assisted enteroscopy is useful in the evaluation of small intestinal lesions and has the advantage of providing biopsies for diagnostic purposes.

DIFFERENTIAL DIAGNOSIS

- Ulcerative colitis
- Appendicitis
- Infection:
 - Mycobacterium tuberculosis
 - Salmonella, Shigella dysenteriae
 - Campylobacter jejuni, Aeromonas spp.
 - Yersinia enterocolitica, Clostridium difficile
 - Escherichia coli, Giardia lamblia, Cryptosporidium, Strongyloides
- Hemolytic uremic syndrome
- Henoch-Schönlein purpura
- Irritable bowel syndrome
- Peptic ulcer disease
- Autoimmune enteropathy, immunodeficiency
- Cow's milk protein allergy
- Small intestinal lymphoma
- Functional disorders

TREATMENT

MEDICATION

- The goal of therapy is resolution of all symptoms in the acute phase (induction), microscopic healing of the intestinal mucosa, steroid-free long-term remission, appropriate growth, and good quality of life. The therapy is used in a stepwise fashion.
- Several 5-aminosalicylic acid (5-ASA) preparations can be trialed according to their intestinal site of activation. These medications can be used for both induction and maintenance of remission of mild to moderate disease but have modest efficacy:
 - Mesalamine (Asacol; terminal ileum, colon): 50–100 mg/kg/24 h

- (max 4.8 g/24 h for active disease and 3.2 g/24 h to maintain remission)
- Mesalamine (Pentasa; duodenum, jejunum, ileum, colon): 50–100 mg/kg/24 h (max 4 g/24 h for active disease and 3 g/24 h to maintain remission)
 - Sulfasalazine (Azulfidine): 40–60 mg/kg/24 h (max 4 g/24 h) for active disease, and 30 mg/kg/24 h (max 2 g/24 h) for maintenance of remission (liquid preparation available)
 - Balsalazide (Colazal; 6.75 g/24 h; 110–170 mg/kg/24 h): can be given to small children as liquid preparation
 - Mesalamine (Rowasa): 4-g enemas and 500-mg suppositories daily to b.i.d. PR
- Corticosteroids can control intestinal inflammation in the acute setting; however, they should not be used long-term for maintenance of remission due to their side-effect profile. An effective starting dose to treat CD is 1–2 mg/kg/24 h IV methylprednisolone or oral prednisone (max 60 mg). Initially, patient is treated for 10 days to 2 weeks and tapered off within several weeks. Topical hydrocortisone is useful in localized left-sided colonic disease and is available in liquid and foam enemas. Corticosteroid with controlled ileal release, budesonide (9 mg/24 h) is available.
 - Exclusive enteral nutrition (EEN): This approach is frequently used in Europe and Canada as a 1st-line therapy to induce remission in lieu of steroids. With EEN, an exclusive elemental or polymeric diet has been reported to be effective in inducing remission, especially in active small bowel disease. Nutritional supplementation in addition to other treatment is also used to correct growth failure. In this setting, it can be given as overnight nasogastric feeding if not tolerated orally. EEN has the appeal of being drug-free but does involve a large commitment from the patient and may be difficult to maintain long-term.
 - Azathioprine, 2–3 mg/kg/24 h PO, and its metabolite 6-mercaptopurine, 1–1.5 mg/kg/24 h, PO are immunomodulators used as maintenance treatment to prevent exacerbations in patients who have been placed in remission with steroids, or biologics and other agents. Adverse events include liver toxicity, leukopenia, and slightly

increased risk of malignancy, specifically lymphoma.

- Methotrexate, another immunomodulator is also used for the maintenance of remission, at the dose of 10–25 mg IM or PO once a week. Adverse effects are similar to azathioprine and 6-mercaptopurine, with the addition of nausea and vomiting, and pulmonary fibrosis.
- Frequent laboratory follow-up is necessary when immunomodulators are used. WBC and platelet count should be monitored carefully. In the case of azathioprine and 6-mercaptopurine, thiopurine methyltransferase (TPMT)—an enzyme catabolizing these drugs—activity or genotype should be determined prior to its use. If TPMT activity is absent (homozygous), these immunomodulators should not be used due to severe risk of myelosuppression via reduced drug clearance. If TPMT activity is intermediate (heterozygous), they should be used in adjusted doses with close monitoring of WBC count.
- Other immunomodulatory therapy used infrequently: cyclosporine, tacrolimus (FK-506), thalidomide, etc.
- Antibiotics can be used for induction of remission, fistulizing disease, or postoperative maintenance of remission; however, their efficacy is modest, and side effects frequently preclude their long-term use.
 - Metronidazole: 15 mg/kg/24 h
 - Ciprofloxacin: 20 mg/kg/24 h
 - Rifaximin: 200 mg t.i.d.–800 mg b.i.d.
- Infliximab, a biologic, chimeric anti-tumor necrosis factor- α antibody (5 mg/kg IV infusion, given every 2–3 months, after initial 3-dose induction therapy at 0, 2, and 6 weeks) for severe and fistulizing disease unresponsive to other therapy. Adalimumab, a humanized anti-TNF- α antibody, was recently approved for use in children with moderate to severe CD (80–160 mg SC at week 0, 40–80 mg at week 2, and 20–40 mg at week 4, and bimonthly thereafter). Both agents can be used for both induction and maintenance of remission. Their side effects include serious infections, anaphylactic reactions, and slightly increased risk of malignancy (lymphoma).
- Other biologic therapies including anti-TNF- α antibody certolizumab and the antiadhesion molecule natalizumab are available but not yet

approved for use in pediatric CD.

- Complementary therapy (probiotics, prebiotics)

SURGERY/OTHER PROCEDURES

- Surgery is reserved for patients with localized CD that is unresponsive to other therapy and that is causing intractable bleeding.
- Surgery may be necessary in stricturing disease, especially in case of proximal intestinal dilatation, and perforation.
- Several types of procedures are available: strictureplasty, abscess drainage, and intestinal resection (side-to-side anastomosis is widely accepted).
- Surgery for CD is not curative, and postoperative recurrence at the site of anastomosis is common.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- The morbidity of CD is high. The majority of patients experience recurring disease.
- Most patients have good general health in between episodes and go on to lead productive lives.
- Carcinoma surveillance is necessary on a regular basis.
- After 5 and 20 years of disease, the probability of survival is 98% and 89% of expected survival, respectively.
- Death is a rare complication (2.4% in a large series).

COMPLICATIONS

- Intestinal obstruction due to strictures, or adhesions
- Abscess or phlegmon formation
- Enteroenteric, enterovesical, enterovaginal, and enterocutaneous fistulas
- Perforation
- Gallstones, kidney stones
- Intestinal lymphoma, colon cancer
- Malabsorption resulting in deficiency (e.g., vitamin B₁₂ and bile salt

deficiency, iron deficiency)

- Short bowel syndrome due to repeated bowel resections
- Massive hemorrhage is rare (1%).
- Growth failure is frequent; final height is reduced, and puberty is delayed in CD affecting prepubertal children.
- Future infertility due to inflammation involving the fallopian tubes and ovaries
- Osteopenia and osteoporosis secondary to inflammation, nutritional deficiency, and therapeutic side effects (corticosteroids)
- Toxic megacolon is a rare but serious complication.

CODES

ICD10

- K50.90 Crohn's disease, unspecified, without complications
- K50.913 Crohn's disease, unspecified, with fistula
- K50.911 Crohn's disease, unspecified, with rectal bleeding

FAQ

- Q: Should the diet of patients with CD be restricted?
- A: One approach to inducing remission in active disease can be to use EEN. However, this approach can be difficult to maintain long-term and should be reserved for those patients who are committed to excluding all other foods. In general, a careful, balanced approach to nutrition in children with CD is required to assure appropriate growth and development. The only foods not recommended are "high-residue foods," including poorly digestible vegetables (if eaten raw), nuts, and popcorn, which can cause obstruction in the narrowed, inflamed intestine. Patients with secondary lactose intolerance should use lactase supplements or avoid milk products while ensuring adequate calories and calcium intake.

CROUP (LARYNGOTRACHEOBRONCHITIS)

Daniel Walmsley

BASICS

DESCRIPTION

- Croup (laryngotracheobronchitis) is a common respiratory illness in children that presents with hoarseness, a characteristic barking cough, rhinorrhea, and fever.
- Spasmodic croup (subglottic allergic edema) refers to an illness characterized by sudden inspiratory stridor at night followed by sudden resolution. Mild cold symptoms may be present but are often absent. The child can have frequent attacks on the same night or for multiple, successive nights.

EPIDEMIOLOGY

- Accounts for 15% of the respiratory illnesses seen in children
- Most commonly occurs in children between 6 and 36 months of age
 - Although cases can be seen up to 6 years of age, it is uncommon in children older than 6 years.
 - Mean age at presentation is 18 months.
- Most prevalent in the fall to early winter
 - October is the most common for parainfluenza viruses.
- More common in males (ratio 1.4:1)
- ER visits for croup are most frequent between the hours of 10 p.m. and 4 a.m.

RISK FACTORS

- Anatomic narrowing of the airway such as in subglottic stenosis or Down syndrome
- Prior history of croup
- Hyperactive airway common in atopic children
- Preexisting airway swelling

ETIOLOGY

In children, the cricoid ring of the trachea, located in the immediate subglottic area, is the narrowest part of their upper airway. A small amount of edema in this region can lead to significant airway obstruction, which is what makes children especially susceptible to this illness.

Caused mainly by respiratory viruses including the following:

- Parainfluenza virus types 1–3, most commonly; accounting for 65% of cases
- Adenovirus
- RSV—in some cases, patients may also have wheezing present
- Influenza virus A, B
- Rhinoviruses
- Enteroviruses
- Metapneumovirus
- Enteric cytopathogenic human orphan virus (echovirus)
- Human coronavirus NL63
- Measles—in areas where measles is prevalent
- Mycoplasma pneumonia—associated with mild cases of croup
- Bacterial infection may occur secondarily by *Staphylococcus aureus*, *Streptococcus pyogenes*, and *Streptococcus pneumoniae*.

DIAGNOSIS

HISTORY

- Croup typically starts with rhinorrhea, cough, coryza, and congestion.
- After a short period (12–48 hours), upper airway obstruction occurs resulting in hoarseness, “barky cough,” and inspiratory stridor.
- Fever is often present.
- Symptoms persist for 3–7 days.
- Usually presents as hoarseness in children older than 6 years of age or adults.

ALERT

The sudden development of inspiratory stridor without other upper respiratory tract infection (URI) symptoms or fever should prompt the consideration of a foreign body aspiration or upper airway mass.

- Recurrent episodes of stridor should lead to the consideration of spasmodic croup, an anatomic abnormality, or an underlying condition such as atopy.
- In a child with truncal or multiple strawberry hemangiomas, a sudden episode of stridor without fever or URI symptoms should raise the concern for a hemangioma in the child's airway.
- Bacterial tracheitis should be suspected in a child who develops marked worsening of symptoms with a high fever after having 5–7 days of mild croup symptoms.

PHYSICAL EXAM

- Examine the child in a comfortable position and make every effort to minimize anxiety, as this can often worsen their symptoms.
- Observe for stridor at rest, irritability, and fatigue. Assess respiratory status and level of consciousness.
- Vital signs:
 - Fever and tachypnea may be present.
 - A child with croup is usually not hypoxic because croup affects the upper airway.
 - Hypoxia is seen only when complete airway obstruction is imminent.
- A child with croup will likely have a hoarse voice, coryza, inflamed pharynx, and varying degrees of respiratory distress.
- The degree of respiratory distress should be observed by assessing for tachypnea, nasal flaring, retractions, grunting, and use of accessory muscles.
- Children with significant upper airway obstruction may sit in a “sniffing” position with their neck mildly flexed and head mildly extended.
 - This position is in contrast to the “tripod” position noted in epiglottitis where the child is in a sitting position with the chin pushed forward and refusing to lie down.
- The presence of inspiratory stridor should be determined.
 - Stridor may be present at rest or only with agitation, and this difference will affect the patient's management.
 - Stridor at rest is a sign of significant upper airway obstruction and

- needs urgent treatment with racemic epinephrine.
- The hydration status of the child should be assessed.
 - Drooling should not be present with croup.
 - Drooling may indicate a different diagnosis such as epiglottitis or peritonsillar abscess.
- The severity of croup can be determined by a clinical scoring system known as the modified Westley Croup Score (see [Table 1](#)).

Table 1. Croup (Laryngotracheobronchitis)—Severity Score for Croup Patients (Westley Croup Score)

Indicator of Severity of Illness	Score
<u>Inspiratory stridor</u>	
None	0
At rest, with stethoscope	1
At rest, w/o stethoscope	2
<u>Retractions</u>	
None	0
Mild	1
Moderate	2
Severe	3
<u>Air entry</u>	
Normal	0
Decreased	1
Severely decreased	2
<u>Cyanosis</u>	
None	0
With agitation	4
At rest	5
<u>Level of consciousness</u>	
Normal	0
Altered mental status	5

- Score <3: mild disease
- Score of 3–6: moderate disease
- Score >6: severe disease

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Croup is a clinical diagnosis, and laboratory tests are not needed.
- The anxiety associated with blood draws may actually worsen the child's condition.
- Rapid antigen tests to determine the viral agent responsible for the illness may be helpful if the child has an atypical presentation or for infection control if the child requires admission.

Imaging

- Radiographs may be helpful to rule out other causes of stridor; they should be considered in children with atypical courses, recurrent episodes, failure to respond to treatment, or if a foreign body is suspected (although of note, most foreign bodies are not radio-opaque).
- Classically, an anteroposterior view demonstrates the “steeple” sign, which is a narrowed air column in the subglottic area.

Diagnosis Procedures/Surgery

- Pulse oximetry
- Visual inspection of the airway via bronchoscopy and direct or fiberoptic laryngoscopy may be helpful in cases of recurrent croup to rule out an anatomic abnormality. In spasmodic croup, noninflammatory edema may be seen of the airway suggesting atopy.

Pathologic Findings

- Gross pathology: edema and erythema of the subglottic trachea; occasionally, pseudomembranes or exudate are noted.
- Microscopic: edema of airway lining with infiltration of neutrophils, histiocytes, plasma cells, and lymphocytes

DIFFERENTIAL DIAGNOSIS

ALERT

Cases of epiglottitis still occur in unimmunized and underimmunized children; therefore, it is important to check the child's immunization

status.

Other important diseases to consider in the differential include the following:

- Infectious
 - Acute epiglottitis
 - Bacterial tracheitis
 - Retropharyngeal abscess
 - Adenotonsillitis
 - Diphtheria
 - Pneumonia
 - Ulcerative laryngitis
- Allergic/inflammatory
 - Asthma
 - Anaphylaxis
 - Angioedema
 - Microaspiration secondary to gastroesophageal reflux or hypotonia
- Environmental
 - Foreign body aspiration
 - Caustic ingestion or burn
 - Smoke inhalation
 - Paraquat poisoning
- Traumatic
 - Subglottic edema/stenosis postintubation
 - Laryngeal or subglottic hematoma
 - Laryngeal fracture
- Obstruction/masses
 - Papillomatosis
 - Hemangioma
 - Cystic hygroma
 - Lymphoma
 - Rhabdomyosarcoma
 - Thymoma
 - Teratoma
 - Thyroglossal duct cyst
 - Branchial cleft cyst

- Congenital anomalies of the upper airway
 - Tracheomalacia/laryngomalacia
 - Vascular ring
 - Laryngeal web
- Genetic/metabolic
 - Hypocalcemia

TREATMENT

INITIAL STABILIZATION

- Racemic epinephrine
- Corticosteroids
- Oxygen (if needed)
- Endotracheal intubation is very rarely required, noted to occur about 1% of the time in studies.

General Measures

- Children with mild symptoms can be treated with humidity, antipyretics, and oral hydration at home. However, randomized controlled trials (RCTs) have not demonstrated a benefit for the use of humidity.
- Short, acute episodes of stridor can be treated with cool mist, a bathroom filled with steam from a shower or cold night air. If the stridor persists, worsens, or occurs at rest, the child should be seen in the emergency room.
- It is important to try to keep the child calm, as agitation or anxiety can worsen symptoms and increase work of breathing.

ALERT

In the child with impending respiratory failure, prompt intubation and direct visualization of the airway in the operating room is imperative. Do not wait for x-rays to confirm a diagnosis.

MEDICATION

- Corticosteroids and nebulized racemic epinephrine, which are the main treatments for croup, have resulted in a dramatic reduction in the

number of admissions and length of hospital stays in patients with croup.

- Dexamethasone (PO or IM; half-life 36–54 hours) 0.6 mg/kg single dose (max 10 mg) has been shown to reduce symptoms in patients with moderate to severe croup.
 - Oral dexamethasone is the most cost-effective steroid treatment available.
 - It has been shown to start having an effect within 30 minutes.
- Alternatively, prednisolone 1–2 mg/kg for 1–3 daily doses can be used to treat a patient with croup, although there is no RCT evidence for this method. A recent double-blinded randomized trial demonstrated that a single dose of 1 mg/kg of prednisolone was NOT as effective at keeping children from emergency medical care as 0.15 mg/kg of dexamethasone.
- Budesonide given via nebulizer at a dose of 2 mg administered q12h—shown in recent studies to be as effective as dexamethasone in reducing symptoms; less systemic absorption compared with dexamethasone, with maximum deposition of drug in the upper airway. Although widely accepted, budesonide is not as readily used as dexamethasone because it is not as cost-effective.
- Racemic epinephrine: A nebulized racemic epinephrine treatment offers immediate reduction in swelling of the laryngeal airway in children who present in extreme respiratory distress. Dose: 0.5 mL of 2.25% solution (D- and L-isomers) in 2.5 mL normal saline delivered via nebulizer as needed.
- L-epinephrine: If racemic epinephrine is not available, 5 mL of L-epinephrine 1:1,000 delivered via nebulizer is effective.

INPATIENT CONSIDERATIONS

Admission Criteria

- Severe respiratory distress on presentation (Croup score of >3)
- Persistent hypoxia despite treatment with steroids and racemic epinephrine
- Requirement of treatment of racemic epinephrine more than once over a 3- to 4-hour period
- Dehydration or risk for dehydration

- Admission should be strongly considered for children who present symptomatically to an ER more than once and have significant stridor on day 1 of illness as croup is usually worse on days 2–3.

Discharge Criteria

- Croup score of ≤ 3 over a 1- to 3-hour period of observation
- Does not require racemic epinephrine in the 3–4 hours prior to discharge
- Able to take adequate PO fluids

ISSUES FOR REFERRAL

- The vast majority of children with croup do well. However, transfer to a facility where trained individuals can address pediatric airway problems should be considered if the patient is inadequately responding to treatment or has increasing respiratory distress.
- A recent study showed heliox during transport for children with severe croup provided added benefit to their prognosis.

PROGNOSIS

- The vast majority of patients do not require hospitalization.
- Almost all patients go on to complete recovery.

COMPLICATIONS

- Poor oral intake/dehydration
- Hypoxia
- Upper airway obstruction
- Respiratory failure (rare)

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- In most cases, the illness is self-limited, lasting 3–5 days.
- A “rebound phenomenon” with worsening of stridor and respiratory distress after initial relief with the racemic epinephrine treatment may be seen up to 2 hours post treatment in some patients.
- Dexamethasone has a half-life of 36–54 hours so parents should be

warned that some children may have worsening in 2 days after treatment with this medication.

- Several studies have shown that children can be safely discharged 3–4 hours after racemic epinephrine treatment.

ALERT

Recurrent croup may signal an underlying anatomic problem and needs evaluation for other causes.

CODES

ICD10

- J05.0 Acute obstructive laryngitis [croup]
- J40 Bronchitis, not specified as acute or chronic

CRYING

Mark F. Ditmar

BASICS

DESCRIPTION

- Crying is usually a normal physiologic response to stress, discomfort, unfulfilled needs such as hunger, pain, over- or understimulation, or temperature change.
- Crying is felt to be potentially pathologic if it is interpreted by caregivers as differing in quality and duration without apparent explanation and/or persists without consolability beyond a reasonable time (generally 1–2 hours).

EPIDEMIOLOGY

- Excessive crying in the first months of life, per parental reports, occurs in about 1 in 5 infants.

ETIOLOGY

- The most likely cause of inconsolable crying in the first few months of life is infantile colic.
 - However, colic is a diagnosis of exclusion.
 - Practitioners must be familiar with the clinical pattern of infantile colic so that deviations are readily recognized.
- Organic problems are identified in 5% or less of afebrile excessively crying infants.

DIAGNOSIS

HISTORY

- **Question:** Colic?
- **Significance:**
 - Colic less likely as a cause if onset after 1 month of age or persistent in infants >4 months of age
 - Recurrent episodes, particularly with a diurnal or evening pattern,

are more likely due to colic.

- Crying shortly after feeding suggests aerophagia or gastroesophageal reflux; 1 hour after feeding suggests formula intolerance. A rare cause of postprandial crying is anomalous coronary arteries.
- Overfeeding or underfeeding, excessive air swallowing, inadequate burping, and improper formula preparation may contribute to excessive crying.
- **Question:** Fever?
- Significance: Indicates potential need for evaluation of meningitis, other infections
- **Question:** Paradoxically increased crying (attempts at consolation make the crying worse, especially with lifting, rocking)?
- Significance: Can be seen in meningitis, peritonitis, long bone fractures, arthritis
- **Question:** Stridor?
- Significance: Implies possible upper airway obstruction (mechanical, functional)
- **Question:** Expiratory grunting?
- Significance: Indicates higher likelihood of significant pathologic cause of crying (especially cardiac, respiratory, and/or infectious disease)
- **Question:** Cold symptoms and/or day care attendance?
- Significance: Increase likelihood of otitis media
- **Question:** Vomiting?
- Significance: Increases likelihood of pathologic GI cause (e.g., obstruction, gastroesophageal reflux with possible esophagitis), particularly in infant <3 months of age, or CNS disease
- **Question:** Recent fall or trauma?
- Significance: May indicate possible fracture, increased intracranial pressure, abuse
- **Question:** Documented weight loss outside of the 2-week neonatal period?
- Significance: Suggests an organic cause

PHYSICAL EXAM

- **Finding:** Infant appears ill (e.g., pallor, grunting, poor arousability, poor response to social overtures)?
- Significance: Implies much higher likelihood of an organic cause
- **Finding:** Tenderness on palpation of extremities, clavicle, or scalp or painful or decreased range of motion of joints?
- Significance: Suggests fracture, subluxation, osteomyelitis, septic arthritis
- **Finding:** Conjunctival redness, eye tearing, scratches near the eye?
- Significance: Suggest corneal abrasion (fluorescein testing of eye warranted) or foreign body in eye (eversion of lid recommended). Cessation of crying with ophthalmic anesthetic drops while doing fluorescein staining suggests corneal injury as a cause.
- **Finding:** Impacted or bloody stool on rectal exam, abdominal mass?
- Significance: Suggest constipation or intussusception
- **Finding:** Geographic scars, frenulum tears, retinal hemorrhages, suspicious bruises, burns, decreased weight/height ratio?
- Significance: Suggest neglect/abuse (physical, emotional). Bruises are rare in preambulatory children (particularly <6 months of age); if present, consider inflicted injuries.
- **Finding:** Bulging or full fontanel (especially in upright, quiet infant)?
- Significance: Indicates possible increased intracranial pressure (meningitis, subdural hematoma, vitamin A toxicity)
- **Finding:** Edema of individual toes, fingers, or penis?
- Significance: Suggest hair tourniquet syndrome
- **Finding:** Tender swelling in inguinal or scrotal area?
- Significance: May indicate incarcerated hernia, testicular torsion
- **Finding:** Heart rate >200 bpm with minimal variability?
- Significance: Indicates possible supraventricular tachycardia
- **Finding:** Hypothermia?
- Significance: Suggests infections or hypothyroidism

DIAGNOSTIC TESTS & INTERPRETATION

- **Test:** Stool for occult blood
- Significance: Possible intussusception, anal fissure
- **Test:** Fluorescein testing of eye
- Significance: Corneal abrasion (may occur without significant

conjunctival redness)

- **Test:** Urinalysis/urine culture
- Significance: UTI
- **Test:** Urine toxicology screen
- Significance: Drug withdrawal (neonatal), ingestions, passive exposures (e.g., cocaine)
- **Test:** Pulse oximetry
- Significance: Hypoxia (from cardiac causes) may cause increased irritability.
- **Test:** Electrolyte panel/blood glucose
- Significance: Endocrine or metabolic disturbance, especially if abnormal sodium, hypoglycemia, significant acidosis, or elevated anion gap
- **Test:** Skeletal survey
- Significance: Suspected abuse; also consider MRI or head CT scan for those <1 year of age with suspicious injuries

DIFFERENTIAL DIAGNOSIS

- Congenital/anatomic
 - Intussusception
 - Gastroesophageal reflux/esophagitis
 - Volvulus
 - Gaseous distention (secondary to improper feeding or burping)
 - Incarcerated inguinal hernia
 - Peritonitis (acute abdomen)
 - Testicular/ovarian torsion
 - Constipation
 - Anal fissure
 - Meatal ulceration
 - Glaucoma
 - Urinary retention (secondary to posterior urethral valves)
 - Cardiac—anomalous coronary artery, hypoxia, congestive heart failure (CHF)
 - Increased intracranial pressure (hydrocephalus, tumor, pseudotumor cerebri)
- Infectious

- Otitis media/externa
- UTI/pyelonephritis
- Stomatitis/gingivitis
- Meningitis/encephalitis
- Diskitis
- Gastroenteritis
- Mastitis
- Arthritis, septic
- Osteomyelitis
- Perianal cellulitis
- Balanitis
- Dermatitis (especially pruritic as in scabies or painful as in staphylococcal scalded skin syndrome)
- Toxic, environmental, drugs
 - Neonatal drug withdrawal
 - Prenatal/perinatal cocaine exposure
 - Immunization reactions (especially DTP)
 - Isolated fructose intolerance
 - Drug reactions (especially antihistamines, pseudoephedrine, phenylpropanolamine), including maternal medications in breast milk
 - Vitamin A toxicity
 - Carbon monoxide exposure
 - Emotional/physical neglect
 - Foreign body ingestion (coin, pin)
 - Ear foreign body (e.g., cockroach)
- Trauma
 - Corneal abrasion
 - Foreign body (hypopharynx, eye, ear, nose)
 - Skull fracture/subdural hematoma
 - Intracranial hemorrhage
 - Retinal hemorrhage (e.g., shaken baby syndrome)
 - Other fractures (especially extremities)
 - Hair tourniquet syndrome (encircling finger, toe, penis, clitoris)
 - Open diaper pin

- Bite (human, animal, insect)
- Genetic/metabolic
 - Sickle cell crisis
 - Phenylketonuria
 - Hypothyroidism
 - Electrolyte abnormalities (especially sodium)
 - Hypoglycemia
 - Hypocalcemia
 - Hypercalcemia
 - Inborn error of metabolism
- Allergic/inflammatory
 - Cow milk allergy
 - Celiac disease (gluten enteropathy)
 - Hemolytic uremic syndrome
 - Henoch-Schönlein purpura
 - Kawasaki disease
- Functional
 - Parental expectations/responses
- Miscellaneous
 - Overstimulation
 - Persistent night awakening
 - Night terrors
 - Caffey disease (infantile cortical hyperostosis)
 - Dysrhythmia (especially supraventricular tachycardia)
 - IV infiltration
 - Autism
 - Teething
 - Headache/migraine
 - Temperament
 - Colic
 - Discomfort (cold, heat, itching, hunger)

ALERT

Factors that make this an emergency include the following:

- Suspicion of meningitis: stiff neck, bulging fontanel, fever (especially infants <2–3 months of age)

- Suspicion of intestinal obstruction: vomiting (especially bilious or projectile), mass on abdominal palpation, and/or bloody stools
- Suspicion of incarcerated hernia or testicular/ovarian torsion
- Evidence of cardiac compromise (CHF, supraventricular tachycardia): tachycardia, poor perfusion (capillary refill >3 seconds, poor distal pulses), rales
- Evidence of acute dehydration: weight loss, decreased urine output, orthostatic changes, poor perfusion
- Evidence of child abuse or neglect

TREATMENT

APPROACH TO THE PATIENT

General goal is to decide if the crying represents a normal physiologic response, a protracted multifactorial physiologic/developmental response (colic), or a potentially pathologic problem.

- **Phase 1:** How urgent is the need for evaluation? A classic and difficult triage issue. One must identify the periodicity of the problem, associated symptoms, impression of wellness, and parental anxiety/reliability.
- **Phase 2:** When in doubt, particularly if colic seems unlikely, see the patient as soon as possible. Treatment is then based on the most likely diagnosis following evaluation. Be wary of the infant who, despite a period of observation, is not noted at any point to be awake and calm.

CODES

ICD10

- R68.11 Excessive crying of infant (baby)
- R10.83 Colic
- K21.9 Gastro-esophageal reflux disease without esophagitis

FAQ

- Q: How important is lab testing in the evaluation of the crying infant?
- A: History and physical exam, rather than extensive lab testing, are the keys to the diagnosis. In Freedman's emergency department (ED) study of 237 excessively crying infants, less than 1% had testing contribute to the diagnosis in the absence of a suggestive clinical picture.
- Q: How might the quality of cry be helpful in the diagnosis?
- A: Subjective interpretation can be helpful.
 - High-pitched (shrill, piercing) crying in short bursts: associated with CNS pathology, especially with increased intracranial pressure
 - High-pitched crying in longer bursts: seen in small-for-gestational age infants, neonatal drug withdrawal
 - Hoarse crying: seen in hypothyroidism, laryngeal diseases, hypocalcemic tetany
 - Weak crying: may be seen in neuromuscular disorders, infant botulism, and/or the very ill infant
 - Catlike cry: can be associated with cri du chat syndrome (5p-syndrome or absence of short arm of chromosome 5)

- Q: How common is teething as a cause of excessive crying?
- A: Patients' families often suggest teething as a cause of excessive crying (as well as fever, diarrhea, rashes, etc.). Objective data do not support a strong association. Be careful in ascribing symptoms and signs to teething.

CRYPTOCOCCAL INFECTIONS

Eric S. Kirkendall • Samir S. Shah

BASICS

DESCRIPTION

Cryptococcosis is an opportunistic fungal infection caused by *Cryptococcus neoformans* that may involve several organ systems, including the CNS, lungs, bones, visceral organs, and skin. *Cryptococcus gattii* is a less common cause.

EPIDEMIOLOGY

- Most pediatric infections occur in immunocompromised hosts, including those with malignancy, HIV, and solid organ or bone marrow transplantation.
- 20% of infections requiring hospitalization occur in normal hosts.
- There is no person-to-person spread.
- Occurs in 5–15% of HIV-infected adults, usually with CD4+ lymphocyte counts <50 cells/mm³; occurs in 0.8–2.3% of HIV-infected children. The lower infection rate in children reflects lower exposure to sources of *C. neoformans*. Seroprevalence varies by age: neonates, 0%; school-aged children, 4.1%; and adults, 69%.
- 1–3% of solid organ transplant recipients develop *C. neoformans* infections, typically >1 year after transplantation.

GENERAL PREVENTION

- Use of highly active antiretroviral therapy (HAART) prevents most cases of cryptococcosis in HIV-infected patients.
- Primary prophylaxis with fluconazole prevents new-onset cryptococcal disease in HIV-infected patients but is not routinely recommended except for those with limited access to HAART and with high levels of antiretroviral drug resistance.
- Maintenance (suppressive) therapy after completion of therapy for cryptococcal infection is recommended for HIV-infected patients. In those with low CD4+ lymphocyte counts, relapse is 100% without

maintenance antifungal therapy, 18–25% with amphotericin B or itraconazole, and 2–3% with fluconazole.

- Prophylaxis may be discontinued in patients receiving HAART with CD4+ lymphocytes $>100/\text{mm}^3$ and undetectable viral loads.
- There is no consensus on the duration of fluconazole suppressive therapy after treatment of cryptococcosis in HIV-negative immunocompromised patients. Most experts provide maintenance (suppressive) antifungal therapy with fluconazole PO (6 mg/kg/day) for at least 1 year after the completion of acute treatment and then reassess ongoing use based on the level of immunosuppression.

PATHOPHYSIOLOGY

- Primary infection occurs through the inhalation of aerosolized soil particles containing the yeast forms. The skin and GI tract are also portals of entry.
- Protective immune response requires specific T cell-mediated immunity.
- CNS infection with *C. neoformans* results from hematogenous dissemination.

COMMONLY ASSOCIATED CONDITIONS

- *C. neoformans* is the most common cause of fungal meningitis in the United States.
- Dissemination is rare in immunocompetent patients.
- Concurrent *Pneumocystis jirovecii* pneumonia was detected in 13% of adults with cryptococcal meningitis.
- Pulmonary involvement is asymptomatic in up to 50% of cases, and disease may be either focal or widespread.
- Bone involvement occurs in 10% of cases of disseminated cryptococcal infection.
- Cutaneous involvement mimics acne-type eruptions that ulcerate and results from hematogenous spread of the organism or from direct extension of bone infection.

DIAGNOSIS

HISTORY

- Cryptococcal meningitis may present as either an indolent infection or acute illness.
- Symptoms of cryptococcal meningitis include headache, malaise, and low-grade fever. Nausea, vomiting, altered mentation (including behavioral changes), and photophobia are less common. Stiff neck, focal neurologic symptoms (e.g., decreased hearing, facial nerve palsy, or diplopia), and seizures are rare.
- Primary pulmonary cryptococcal disease is not well described in children because most cases are disseminated at the time of diagnosis. 50% of adults have cough or chest pain, and fewer have sputum production, weight loss, fever, and hemoptysis.
- In immunocompromised hosts, the onset of infection is more rapid and the course more severe. Pulmonary involvement is minimal when dissemination occurs quickly.

PHYSICAL EXAM

- None of the presenting signs of cryptococcal infection are sufficiently characteristic to distinguish it from other infections, particularly in immunocompromised patients.
- CNS involvement: nuchal rigidity, photophobia, and focal neurologic deficits
- Respiratory tract involvement: cough, tachypnea, grunting, and subcostal or intercostal retractions. Decreased breath sounds or dullness to percussion may be present, or the lung exam may be normal.
- Cutaneous manifestations: erythematous or verrucous papules, nodules, pustules, acneiform lesions, ulcers, abscesses, or granulomas. Lesions can occur anywhere but are found most often on the face and neck.
 - Mucocutaneous findings are present in 10–15% of cases of disseminated disease.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Lumbar puncture: diagnose cryptococcal meningitis
 - CSF should be sent for cell count and differential; protein; glucose;

cultures for bacterial, fungal, and viral pathogens; and cryptococcal antigen. A large quantity of CSF may be needed to recover the organism.

- Examination of the CSF reveals <500 WBC/mm³ (usually <100 WBC/mm³), mostly mononuclear leukocytes, with minimal changes in protein. CSF glucose is <50 mg/dL in ~65% of patients.
- India ink stain (less commonly performed) shows budding yeast in 50% of cases.
- CSF cultures are positive in ~90% of cases.
- The latex agglutination test for cryptococcal polysaccharide antigen is specific, sensitive, and rapid. Titers $\geq 1:4$ suggest the diagnosis of cryptococcal infection if appropriate controls are negative.
- HIV-infected patients with pneumonia and CD4+ T-lymphocyte counts <200 cells/mm³ should be evaluated with sputum fungal culture, blood fungal culture, and a serum cryptococcal antigen test. A lumbar puncture to exclude the possibility of occult meningitis should be considered. If any test is positive for *C. neoformans*, then a lumbar puncture should be performed to exclude cryptococcal meningitis.
- Blood culture and serum cryptococcal antigen titers: diagnose disseminated cryptococcal infection. Serum cryptococcal antigen tests are positive in $>90\%$ of patients with cryptococcal meningitis.
- Sputum culture: diagnose cryptococcal pneumonia
- Skin or bone biopsy: diagnose cutaneous or osteoarticular cryptococcal infection
- HIV testing: Evaluation for immunodeficiencies, including HIV, is warranted in any patient with cryptococcosis.
- CBC with differential: may reveal hypereosinophilia (absolute eosinophil count $>1,500$ /mm³)
- Serum electrolytes: detect hyponatremia, a complication of cryptococcal meningitis

Imaging

- Chest x-rays: Focal or solitary nodules, diffuse infiltrates, and pleural effusions may be seen in cryptococcal pneumonia.
- Head CT or MRI: may demonstrate granulomatous lesions

(cryptococcomas; ~15% of patients with meningitis) or elevated intracranial pressure. MRI reveals dilation of perivascular spaces in almost half the cases.

DIFFERENTIAL DIAGNOSIS

- Although cryptococcosis occurs most commonly in HIV-infected patients with low CD4⁺ lymphocyte counts, the diagnosis warrants consideration in all febrile immunocompromised children (e.g., solid organ transplant, leukemia)
- Meningitis: viruses, *Mycobacterium tuberculosis*, and other fungal causes
- Pneumonia: other pulmonary mycoses, including aspergillosis, histoplasmosis, and blastomycosis; also consider *Mycoplasma pneumoniae* and *M. tuberculosis*
- Bone: osteogenic sarcoma
- Cutaneous: molluscum contagiosum, herpes simplex virus infection, pyoderma gangrenosum, and cellulitis

TREATMENT

- Clinical management depends on extent of disease and immune status of the host.
- Pulmonary and extrapulmonary disease (HIV-negative, nontransplant)
 - Normal hosts with isolated pulmonary nodules may not need treatment if the serum cryptococcal antigen is negative and the patient is asymptomatic.
 - Patients with symptoms, extensive pulmonary disease, or evidence of extrapulmonary disease require treatment.
 - Fluconazole 6–12 mg/kg/24 h PO (max 400 mg) for 6–12 months for mild/moderate disease. Alternate regimen: itraconazole 5–10 mg/kg/24 h PO (max 400 mg) for 6–12 months (steady-state trough level >1 mcg/mL and ≤10 mcg/mL) or amphotericin B 0.7–1 mg/kg/24 h IV for 3–6 months
 - Severe disease: same as CNS (see below)
 - Maintenance therapy with fluconazole should be considered for

immunocompromised patients (see “[General Prevention](#)”).

- Pulmonary and extrapulmonary disease (HIV-infected or transplant)
 - Fluconazole (PO) 6–12 months for mild/moderate disease; same as CNS infection for severe disease
 - Consider surgical debridement for patients with persistent or refractory pulmonary or bone lesions.
- CNS disease (HIV-negative, nontransplant)
 - Induction/consolidation: amphotericin B (0.7–1 mg/kg/24 h) plus flucytosine (100–150 mg/kg/24 h PO, divided q6h; therapeutic levels: 25–100 mg/L) for 4 weeks, then fluconazole PO (10–12 mg/kg/day) for a minimum of 8 weeks followed by maintenance therapy with fluconazole PO (6 mg/kg/24 h) for 6–12 months. Alternate induction/consolidation regimen: amphotericin B plus flucytosine for 6–10 weeks
- CNS disease (HIV-infected or transplant)
 - Induction/consolidation: amphotericin B (IV) plus flucytosine (PO) for at least 2 weeks, followed by fluconazole PO (10–12 mg/kg/day) for at least 8 weeks; consider subsequent suppressive therapy with fluconazole PO (6 mg/kg/24 h).
 - Intrathecal amphotericin B is very toxic but may be used in refractory cases.
 - HIV-infected patients require continuation of antifungal drugs indefinitely because of the high recurrence rate of cryptococcosis.
 - Liposomal amphotericin (5 mg/kg/24 h) or amphotericin B lipid complex (5 mg/kg/24 h) IV may be substituted for amphotericin B, especially in patients with renal dysfunction and those receiving calcineurin inhibitors.
 - Flucytosine is used only in combination with amphotericin B and not as a single agent because of the rapid emergence of drug resistance.
- Voriconazole, a triazole antifungal agent, demonstrates excellent in vitro activity against *C. neoformans* but requires clinical study. Caspofungin, an echinocandin antifungal agent, is not active against *C. neoformans*.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Because of the risk of relapse, patients should be seen at 3-month intervals for 12–18 months following treatment. Immunocompromised patients should be evaluated every 2–3 months, even while on suppressive therapy, to monitor clinically for relapse.
- Repeat lumbar punctures documenting a decrease in CSF cryptococcal antigen and sterility of culture are useful in evaluating response to treatment. During therapy for acute meningitis, an unchanged or increased titer of CSF antigen correlates with clinical and microbiologic failure to respond to treatment. Serum antigen titers are not helpful for this purpose.
- Evaluate patients with cryptococcal meningitis for neurologic sequelae.
- HIV-infected patients require suppressive antifungal therapy (see “[General Prevention](#)”).

PROGNOSIS

- Mortality is rare in patients with isolated pulmonary or cutaneous disease.
- In-hospital mortality is ~20% for cryptococcal meningitis and ~8% for non-CNS cryptococcal infections.
 - In normal hosts with meningitis, poor prognostic factors include serum or CSF cryptococcal titers $>1:32$ or CSF WBC $<20/\text{mm}^3$.
 - In HIV-infected patients with meningitis, poor prognostic factors include hyponatremia, concomitant growth of *C. neoformans* from another site, increased intracranial pressure, and any alteration of mental status.
- Up to 40% of patients with cryptococcal meningitis have residual neurologic deficits.
- Relapse rates are high in HIV-infected patients (see “[General Prevention](#)”).

COMPLICATIONS

- Elevated intracranial pressure with meningitis

- Pulmonary, cutaneous, and bone involvement may occur (see “[Commonly Associated Conditions](#)”).
- In solid organ transplant patients, tacrolimus recipients are less likely to have CNS involvement and more likely to have skin, soft tissue, or osteoarticular involvement.
- Cryptococcal immune reconstitution inflammatory syndrome (C-IRIS) may lead to a new presentation of the disease and/or a clinical deterioration after reversal of a host immune deficiency state.

CODES

ICD10

- B45.9 Cryptococcosis, unspecified
- B45.0 Pulmonary cryptococcosis
- B45.1 Cerebral cryptococcosis

FAQ

- Q: What are the sources of *Cryptococcus* in nature?
- A: Pigeon droppings and soil. Naturally acquired infections occur in

lower mammals, especially cats. However, neither animal-to-human nor human-to-human infections have been reported.

- Q: Should all children with *Cryptococcus* infection be evaluated for immunodeficiency?
- A: Yes.

CRYPTORCHIDISM

Hsi-Yang Wu

BASICS

DESCRIPTION

Cryptorchidism is a condition characterized by one or both testes being undescended. An undescended testis does not remain at the bottom of the scrotum after the cremaster muscle has been fatigued by overstretching. Cryptorchidism is commonly confused with a retractile testis. A retractile testis may not always lie in the scrotum but will stay at the bottom of the scrotum after overstretching the cremaster.

EPIDEMIOLOGY

- 3% of full-term newborn boys have cryptorchidism.
- This percentage falls to 1% by 3 months of age.
- There are 2 peaks for detection of undescended testes: at birth and at 5–7 years of age. The latter group probably represents those patients with low undescended testes that become apparent with linear growth.
- Bilateral undescended testes occur in 10% of patients with undescended testicles.
- Unilateral anorchia is found in 5% of patients with cryptorchidism.

Genetics

- Of boys with undescended testes, 4% of their fathers and 6–10% of their brothers also had undescended testes. There is a 23% prevalence of cryptorchidism in family members of cases compared to 7.5% of relatives of controls.
- Androgen receptor gene mutations are not linked to isolated cryptorchidism. Abnormalities in HOXA10, HOXA11, HOXD13, ESR1, INSL3, and the LGR8/GREAT receptor genes are being investigated in patients with cryptorchidism.

PATHOPHYSIOLOGY

- Normal testicular descent occurs during the 7th month of gestation.
- The majority of testes that are undescended at birth but will descend

spontaneously do so by 3 months of age, possibly due to the gonadotropin surge that is responsible for germ cell maturation.

- The undescended testis fails to show normal maturation at both 3 months and 5 years of age.
 - At 3 months of age, the fetal gonocytes are transformed into adult dark spermatogonia.
 - At 5 years of age, the adult dark spermatogonia become primary spermatocytes.
 - Both of these steps are abnormal in the undescended testis and, to a lesser extent, the contralateral descended testis.
 - Previous beliefs that the undescended testis was normal between birth and 1 year of age are incorrect because they were derived from counts of all germ cells without taking into account whether maturation was occurring.
 - After 5 years of age, thermal effects on the testis left out of position are seen independent of the endocrinologic effects.

ETIOLOGY

- A multifactorial mechanism involving 2 theories have been postulated:
 - Hypogonadotropic hypogonadism
 - Abnormal mechanical factors (gubernaculum, epididymis, genitofemoral nerve innervation, intra-abdominal pressure)
- Although boys with undescended testes do have abnormal attachment of the gubernaculum, the mechanical theories do not consistently explain the testis histology found in cryptorchidism.
- Many boys with cryptorchidism have lower morning urinary luteinizing hormone and a decreased luteinizing hormone/follicle-stimulating hormone response to gonadotropin-releasing hormone, corresponding to the abnormal germ cell development in both the undescended and contralateral descended testis.
- The normal initial postnatal gonadotropin surge at 60–90 days of age is absent or blunted in some boys with cryptorchidism. Without this surge, Leydig cells do not proliferate, testosterone does not increase, germ cells do not mature, and infertility may develop. This indicates that a mild endocrinopathy is responsible, and cryptorchidism may be a variant of hypogonadotropic hypogonadism.

- Secondary undescended testes can occur after inguinal surgery, either due to scar tissue or difficulty in diagnosing an undescended testis in a young boy with a hernia.

COMMONLY ASSOCIATED CONDITIONS

- Patients with prune belly, Klinefelter, Noonan, and Prader-Willi syndromes have a higher likelihood of undescended testes.
- Cryptorchidism associated with hypospadias should also raise the possibility of a disorder of sex development (DSD), which occurs in 30–40% of patients, mainly consisting of defects in gonadotropin or testosterone synthesis.

DIAGNOSIS

HISTORY

- Exogenous maternal hormones (used in infertility treatments)
- Maternal oral contraceptive use
- Consanguinity
- Family history of urologic abnormalities or neonatal deaths
- Prematurity
- CNS lesions
- Previous inguinal surgery
- Precocious puberty
- Infertility

PHYSICAL EXAM

- The undescended testis may be found at the upper scrotum, in the superficial inguinal pouch, or in the inguinal canal. For treatment purposes, the main distinction that needs to be made is whether or not the testis is palpable.
- The patient should be examined sitting in the frog-leg position.
 - With warmed hands, check the size, location, and texture of the contralateral descended testis.
 - Begin the examination of the undescended testis at the anterior superior iliac spine.
 - Sweep the groin from lateral to medial with the nondominant hand.

- Once the testis is palpated, grasp it with the dominant hand and continue to sweep the testis toward the scrotum with the other hand.
- With a combination of sweeping and pulling, it is sometimes possible to bring the testis to the scrotum.
- Maintain the position of the testis in the scrotum for a minute so that the cremaster muscle is fatigued.
- Release the testis, and if it remains in place, it is a retractile testis.
- If it immediately pops back, it is an undescended testis.
- For difficult-to-examine patients (chubby 6-month-olds or obese youth), having them sit with heels together and knees abducted can help relax the cremaster. Wetting the fingers of the nondominant hand with lubricating jelly or soap can increase the sensitivity of the fingers in palpating the small, mobile testis.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- For the typical patient with a unilateral palpable or nonpalpable undescended testis, no further laboratory evaluation is necessary.
- For the patient with bilateral undescended testis, with 1 testis palpable, no further workup is necessary.
- The patient with bilateral nonpalpable testes should have a chromosomal and endocrinologic evaluation, as should the patient with 1 or 2 undescended testes and hypospadias.
- If the patient has bilateral nonpalpable testes and is <3 months of age, serum luteinizing hormone, follicle-stimulating hormone, testosterone, and anti-müllerian hormone levels will determine whether testes are present.
- After that age, human chorionic gonadotropin stimulation will result in a measurable serum testosterone if testes are present. A failure to respond to human chorionic gonadotropin stimulation in combination with elevated luteinizing hormone/follicle-stimulating hormone levels is consistent with anorchia.

Imaging

Ultrasound, CT, and MRI can detect testes in the inguinal region, but this is also the region where they are most easily palpable. They are only 50%

accurate in showing intra-abdominal testes. Imaging is not necessary preoperatively because, for nonpalpable testes, surgical planning is based on the exam performed in the clinic and under anesthesia.

DIFFERENTIAL DIAGNOSIS

- Retractable testes are commonly confused with undescended testes. The key to distinguishing them from undescended testes is the physical exam.
 - All retractile and many undescended testes can be delivered into the scrotum.
 - The retractile testis will stay in the scrotum after the cremaster muscle has been overstretched.
 - The low undescended testis will immediately pop back to its undescended position after being released.
- Atrophic or “vanishing” testes are found anywhere along the normal path to the scrotum.
 - They are believed to be due to neonatal vascular ischemia.
 - The contralateral testis can be hypertrophied in these boys, but this is not a reliable diagnostic sign.
- Anorchia or DSD
 - On evaluation, 80% of nonpalpable testes are present in either the abdomen or in the inguinal canal.
 - A child with bilateral nonpalpable testes should have an endocrine evaluation to rule out anorchia or DSD.

TREATMENT

ADDITIONAL TREATMENT

General Measures

- Patients with undescended testes should be referred for surgical evaluation no later than 3 months of age.
- Hormonal therapy
 - Hormonal therapy was widely used in Europe for inducing descent of undescended testes. Both gonadotropin-releasing hormone and human chorionic gonadotropin were used, with long-term success

rates of 20%.

- Treatment is most successful for low undescended testes, but there is a 25% relapse rate.
- More recent recommendations from European pediatric endocrinologists indicate that surgery is the preferred therapy.
- For these reasons, as well as that gonadotropin-releasing hormone and human chorionic gonadotropin are not approved for this indication in the United States, most therapy in the United States to bring the testis down to the scrotum is surgical (orchiopexy).
- The use of hormonal therapy after orchiopexy to improve semen analyses in high-risk patients is in its preliminary stages of investigation in Europe and the United States.

SURGERY/OTHER PROCEDURES

Goals in bringing the testis into the scrotum:

- Prevent ongoing thermal damage to the testis.
- Treat the associated hernia sac.
- Prevent testis torsion/injury against the pubic bone.
- Achieve a good cosmetic result/avoid psychological effects of empty scrotum.
- Allow the older child to perform testicular self-exam for cancer.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

After successful orchiopexy, patients are examined at 6–12 months to check on testicular size and position. They are rechecked at puberty to explain the technique and need for monthly testis self-exam concerning early recognition of testis cancer. Patients with retractile testes should be examined annually until age 7 years because ~5% will be found to have a testis out of the scrotum.

PROGNOSIS

- Surgery cannot reverse the maturational failure of the undescended testis, but it can prevent ongoing thermal injury.

- Parents are often concerned about future fertility:
 - In patients who have undergone orchiopexy at an early age, it appears that 90% of boys with unilateral cryptorchidism and 65% with bilateral cryptorchidism will achieve paternity.
 - Patients who are interested in their risk for infertility may have a semen analysis performed at age 18 years.
- Surgery decreases the relative risk of testicular cancer if the surgery is performed before 13 years of age.
 - All patients should be taught proper monthly testicular self-exam at the time of puberty. Some patients with cryptorchidism are at a higher risk of cancer (prune belly syndrome, ambiguous genitalia, karyotypic abnormalities, or the postpubertal boy).

CODES

ICD10

- Q53.9 Undescended testicle, unspecified
- Q53.10 Unspecified undescended testicle, unilateral
- Q53.20 Undescended testicle, unspecified, bilateral

FAQ

- Q: If there is only 1 testicle in the scrotum, will fertility be affected?
- A: In general, the outlook for paternity is good in a patient with only 1 descended testicle. Paternity is more significantly affected with a history of 2 undescended testicles.
- Q: Why do patients with retractile testes require follow-up?
- A: The ability to distinguish between retractile and undescended testes can be difficult in some patients. Some of the patients will be found to have true undescended testes as they grow. Boys should be taught how to perform a monthly testicular self-exam at puberty.

CRYPTOSPORIDIOSIS

Michelle W. Parker

BASICS

DESCRIPTION

Cryptosporidiosis is protozoal infection causing a self-limited acute gastroenteritis characterized by nonbloody watery diarrhea.

- Symptoms, when present, can also include abdominal pain, fever, fatigue, weight loss, vomiting, headache, and joint pain and typically last 1–2 weeks.
- In an immunocompromised patient, gastrointestinal symptoms can be chronic, relapsing, and severe, causing profound and life-threatening wasting and malabsorption.
- Extraintestinal: Pulmonary, biliary tract (sclerosing cholangitis, acalculous cholecystitis, pancreatitis), or disseminated infection rarely occurs among immunocompromised individuals.

EPIDEMIOLOGY

- Oocysts of *Cryptosporidium* are shed in stool of infected hosts (humans, cattle, and other mammals) and are transmitted by fecal–oral contamination.
- Disease is most commonly associated with contamination of water sources, both drinking and recreational, and transmission is also seen in association with child care centers or livestock.
- *Cryptosporidium* has been found in all parts of the world and is a cause of traveler's diarrhea.
- Because of summer recreational water use, the incidence of cryptosporidiosis is highest in children and typically peaks in summer through early fall.

Incidence

In 2010, nearly 9,000 new cases were reported in the United States. The incidence began increasing in 2005, with a peak in 2007 at just over 11,500 cases.

RISK FACTORS

- Those most at risk of infection are children who attend day care centers, people who take care of others with cryptosporidiosis (including child care workers, parents of infected children, and health care workers), those who swim in or drink from contaminated water sources such as streams or unprotected wells, and people who handle livestock including those visiting petting zoos.
- Because *Cryptosporidium* are chlorine tolerant, swimming in chlorinated pools does not decrease the risk of infection.

GENERAL PREVENTION

- Drinking water should be adequately filtered to a particle size of 1 μm or smaller in order to ensure oocyst removal.
- If a recreational water supply becomes contaminated, it should be closed and proper decontamination measures should be implemented.
- Those diagnosed with cryptosporidiosis should not swim for at least 2 weeks after diarrhea stops to help protect others.
- Good hand hygiene, washing with soap and water vigorously for at least 20 seconds, is key after contact with animals or stool.
- Children with diarrhea should not attend day care settings until diarrhea is resolved.
- In day care settings, disinfection of diapering areas after each use and frequent disinfection of toys, tabletops, and highchairs during outbreaks is recommended.
- Oocysts can survive for long periods and are resistant to many disinfectants including chlorine, iodine, and dilute bleach. Boiling water or full-strength bleach disinfectant is most effective.
- Contact precautions are recommended for the length of the hospital stay for hospitalized patients.
- Immunocompromised persons should avoid contact with any person or animal with cryptosporidiosis.

PATHOPHYSIOLOGY

- Transmission occurs via fecal–oral passage of oocysts from food, water, or poor hand hygiene.
- The incubation period is typically 3–14 days with a median of 7 days,

and oocyst shedding may occur for weeks to months after symptoms resolve. In the majority of people, shedding stops after 2 weeks. Immunocompromised patients can shed for several months.

- Invasion of intestinal epithelial cells in the small intestine and proximal colon leads to a secretory diarrhea.
- Intestinal destruction occurs with villous atrophy and subsequent malabsorption and increased intestinal permeability.

DIAGNOSIS

HISTORY

- Acute onset of symptoms combined with exposure to any of the transmission sources discussed above should prompt consideration. Fever and vomiting are symptoms more commonly found in children and can lead to the misdiagnosis of viral gastroenteritis.
- Immunocompromised patients such as those with AIDS may have chronic severe symptoms with significant wasting.

PHYSICAL EXAM

- Acute weight loss
- Fever
- Tenderness to palpation of abdomen
- Dehydration
- Immunocompromised patients may rarely exhibit respiratory symptoms (dyspnea) or biliary tract symptoms (colicky right upper quadrant pain).

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Detection of organisms in stool specimens is diagnostic. Oocysts are small and may be missed on routine light microscopic examination of stool; modified acid-fast staining may aid in diagnosis.
 - Fluorescent stains such as auramine O are rapid but have high false-positive rates.
 - Immunofluorescent assays and enzyme-linked immunosorbent assays for antigen detection are also available.

- The direct immunofluorescent stain is the diagnostic test of choice.
- Tests for *Cryptosporidium* are not routinely performed and should be specifically requested.

DIFFERENTIAL DIAGNOSIS

- Other infectious etiology of diarrheal illness:
 - Viral gastroenteritis including rotavirus, adenovirus, astrovirus; caliciviruses including norovirus, cytomegalovirus
 - Bacterial gastroenteritis including *Salmonella*, *Shigella*, *Yersinia*, *Campylobacter*, enterotoxigenic *Escherichia coli*, *Vibrio cholerae*
 - *Clostridium difficile* enterocolitis
 - Parasitic gastroenteritis including *Giardia*, *Entamoeba*, *Cyclospora*, *Isospora*, *Microsporidia*
- Noninfectious etiology of diarrheal illness:
 - Allergic colitis, inflammatory bowel disease, irritable bowel syndrome, appendicitis, intussusception, malrotation/volvulus, celiac disease, or other malabsorption

TREATMENT

MEDICATION

- In immunocompetent patients, disease is typically self-limited, and no treatment is necessary.
- For those who are malnourished where treatment is preferred, oral nitazoxanide may be given for 3 days.
- Dosage for children 1–3 years of age is 100 mg b.i.d.; for children 4–11 years of age, 200 mg b.i.d.; and for adults, 500 mg b.i.d.
- For immunosuppressed patients, antiretroviral therapy to improve CD4+ count has been associated with decreasing duration of illness. Nitazoxanide, paromomycin, and bovine immunoglobulin have also been tried without strong data to support efficacy.

ADDITIONAL TREATMENT

General Measures

Fluids and electrolytes should be replaced by oral or intravenous route.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Education

- Because the oocysts can be shed in the stool for weeks after clinical resolution, it is important to realize that asymptomatic patients can still transmit the infection to household and day care contacts.
- Requiring patients whose diarrhea has resolved to have a negative stool test for *Cryptosporidium* before reentry to day care has not been evaluated as an outbreak control measure. Repeated testing is expensive.

PROGNOSIS

- For immunocompetent hosts, gastrointestinal disease is self-limited, usually lasting approximately 10 days. Supportive therapy is usually all that is necessary.
- For immunocompromised patients, diarrhea can be severe, debilitating, and often life threatening. Aggressive supportive therapy is usually required, along with antimicrobial therapy and immune reconstitution.

CODES

ICD10

A07.2 Cryptosporidiosis

FAQ

- Q: For whom should cryptosporidiosis be considered as a differential diagnosis?
- A: For anyone with acute onset of watery diarrhea with any of the mentioned risk factors
- Q: When is it safe for a child with cryptosporidiosis to return to day care?
- A: When the diarrhea has resolved
- Q: For how long is an immunocompetent patient with cryptosporidiosis contagious?
- A: A healthy person may continue to shed for weeks to months after diarrhea has resolved.

CUSHING SYNDROME

Maya B. Lodish • Constantine A. Stratakis

BASICS

DESCRIPTION

Cushing syndrome is a multisystem disorder resulting from prolonged exposure to excess glucocorticoids.

- Characterized by growth deceleration, truncal obesity, characteristic skin changes, muscle weakness, and hypertension
- Most common cause in childhood is exogenous administration of glucocorticoids.
- Endogenous Cushing syndrome may be caused by ACTH-secreting tumor of the pituitary gland (Cushing disease), ectopic secretion of ACTH, or ACTH-independent secretion of glucocorticoids by the adrenal glands.
- Accurate diagnosis and classification of Cushing syndrome in children is crucial to guide appropriate therapeutic intervention.
- In endogenous Cushing syndrome, the hypothalamic-pituitary-adrenal axis has lost its ability for self-regulation due to excessive secretion of either ACTH or cortisol and loss of the negative feedback function.
- Diagnostic tests help to distinguish the cause of this disorder.
- Key differences in the diagnosis and management of Cushing syndrome exist between children and adults.

EPIDEMIOLOGY

- The overall incidence of Cushing syndrome is approximately 2–5 new cases per million people per year. Only approximately 10% of the new cases each year occur in children.
- In older children with Cushing syndrome, there is a female-to-male predominance, whereas in younger children there may be a male predominance.
- Exogenous Cushing syndrome caused by chronic administration of glucocorticoids (by any route) or, more rarely, by administration of ACTH (for example, for infantile seizures) is the most common cause

of this syndrome in children.

- The pituitary-dependent form (Cushing disease) accounts for more than 80% of all cases of Cushing syndrome in children older than 7 years of age.

ETIOLOGY

- Adrenal sources of Cushing syndrome:
 - In very young children, adrenal sources of Cushing syndrome are the most common causes of the condition.
 - 10–15% of all the cases of Cushing syndrome in childhood are due to ACTH-independent Cushing syndrome from unregulated secretion of cortisol from the adrenal glands.
 - Adrenocortical neoplasms
 - Often malignant in young children.
 - Primary pigmented nodular adrenocortical nodular disease (PPNAD)
 - PPNAD is a genetic disorder often associated with Carney complex and related to mutations of the PRKAR1A gene.
 - Cushing syndrome in PPNAD may be cyclical and difficult to diagnose.
 - Isolated micronodular adrenocortical disease (iMAD)
 - If no PRKAR1A mutations are found or if the patient does not have Carney complex, and Cushing syndrome is due to bilateral adrenal hyperplasia without massive enlargement of the adrenal glands on imaging, then, the most likely diagnosis is iMAD.
 - Like in PPNAD, Cushing syndrome in iMAD can be difficult to diagnose due to an often atypical and/or cyclical clinical course.
 - Massive macronodular adrenal hyperplasia (MMAD)
 - Another form of ACTH-independent bilateral adrenal disease seen (rarely) in children
 - Easier to diagnose due to massive enlargement of the adrenal glands on imaging studies
 - Adrenal hyperplasia and/or adenomas can also be seen in the McCune Albright and Beckwith-Wiedemann syndromes, usually in the infantile period.
- Ectopic ACTH production accounts for less than 1% of the cases of

Cushing syndrome in children and may be due to a variety of neuroendocrine (NE) tumors.

- NE tumors include carcinoid tumors in the lungs, pancreas (and other locations in the gastrointestinal tract), or thymus; medullary carcinomas of the thyroid; and pheochromocytomas, as well as small cell carcinoma of the lungs that may be seen rarely in adolescents.
- Other causes of ectopic ACTH secretion include infantile neuroblastomas (and related tumors) and paraneoplastic syndromes in all ages.
- Corticotropin-releasing hormone (CRH) secretion by an ectopic CRH-producing source, typically an NE tumor such as the ones producing ectopically ACTH, is an extremely rare cause of Cushing syndrome in children.
- Exogenous steroids: Iatrogenic Cushing syndrome is the most common cause in pediatrics. Cushing syndrome can be caused by chronic systemic, topical, or intranasal steroid use, or ACTH use.

DIAGNOSIS

HISTORY

- The most common presenting symptom of the syndrome in childhood is weight gain accompanied by poor linear growth.
- Additional pertinent features in the history of presenting illness often include headaches, hypertension, weakness, hirsutism, irregular menses, and delayed puberty.
- Dermatologic features include facial flushing, striae (in older children and adolescents only), acne, bruising, and acanthosis nigricans.
- Fractures and/or kidney stones related to Cushing syndrome are also relatively frequent manifestations.

PHYSICAL EXAMINATION

- Check growth chart and document height velocity and weight change.
- Note fat distribution (characteristic central obesity, dorsocervical, subclavicular, and bitemporal fat pads).

- Skin examination
 - Document striae (usually wide, violaceous) and acanthosis.
 - Look for characteristic dermatologic features that may be associated with genetic forms of Cushing (café au lait spots for MAS, lentigines for Carney complex).
- Neurologic examination
 - Check for proximal muscular weakness (typically not present in younger children) by having patient rise from a squatting position.
 - Check visual fields and perform funduscopic examination.
- Document Tanner staging and note any discrepancy between pubic hair and gonadal or breast size (which may point to ACTH-dependent or -independent causes of Cushing syndrome).

DIAGNOSTIC TESTS & INTERPRETATION

- Diagnostic tests: The first step in the diagnosis of Cushing syndrome is to document hypercortisolism.
- Screening
 - 24-hour urine free cortisol excretion
 - Low-dose dexamethasone test
 - 1 mg dexamethasone (adjust for pediatric patients 15 mcg × weight [kg]; maximum dose 1 mg) PO at 11 p.m. Measure plasma cortisol at 8 a.m. next day.
 - Circadian cortisol profile
 - Measure serum or salivary cortisol at 8 a.m. and midnight.
- Confirmation: The following results are suspicious for Cushing syndrome:
 - 24-hour urine free cortisol excretion above normal limits for assay (corrected for body surface area)
 - Post low-dose dexamethasone 8 a.m. plasma cortisol >1.8 mcg/dL
 - Blunted circadian rhythm: a single midnight cortisol value of >4.4 mcg/dL highly sensitive and specific for Cushing syndrome
- Differentiate causes:
 - Measure plasma ACTH.
 - If low ACTH (<29 pg/mL) = likely ACTH- independent but need to confirm with dexamethasone testing; only completely undetectable ACTH levels indicate undoubtedly an adrenal source of Cushing

syndrome.

- Proceed with high-dose dexamethasone suppression test (adjust dexamethasone dose for weight $120 \text{ mcg} \times \text{kg}$; max dose 8 mg).
- Lack of suppression in response to high-dose dexamethasone indicates that the likely diagnosis is adrenal tumor.
- If high ACTH ($>29 \text{ pg/mL}$) = likely ACTH-independent
 - Proceed with CRH testing (generally done by an endocrine specialist).
 - CRH given at 1 mcg/kg and serial cortisol and ACTH levels are measured. The criterion for the diagnosis of the pituitary-dependent Cushing disease is a mean increase of 20% above baseline for cortisol values at 30–45 minutes and an increase in the mean corticotropin concentrations of at least 35% over basal value at 15–30 minutes after CRH administration.
 - If CRH testing is negative: Likely diagnosis is ectopic ACTH production.
 - If CRH testing is positive: consistent with Cushing disease

Imaging

- When Cushing disease (ACTH-secreting pituitary tumor) is suspected, pituitary magnetic resonance imaging (MRI) should be done in thin sections with high resolution with gadolinium.
- Computed tomography (CT) of the adrenal glands useful in the distinction between pituitary Cushing disease and adrenal causes of Cushing syndrome. MRI of the adrenal glands is less useful for the detection of PPAD or iMAD, but may be used for the detection of MMAD, single large tumors, and cancer.
- Bilateral inferior petrosal sinus sampling (IPSS) is a catheterization study used to confirm the source of ACTH secretion in ACTH-dependent Cushing syndrome. IPSS needed only when the pituitary MRI is negative or tests are contradictory, but may be performed only if ACTH-dependent disease is confirmed and cortisol levels are consistently high.

TREATMENT

- The treatment of choice for Cushing disease is transsphenoidal surgery (TSS).
- In most specialized centers with experienced neurosurgeons, the success rate of the first TSS is close to, or even higher than, 85%.
- The treatment of choice for adrenal tumors is surgical resection, and if metastatic carcinoma, chemotherapy and radiation may be employed.
- Bilateral total adrenalectomy is usually the treatment of choice in PPNAD, iMAD, and MMAD.
- Adrenalectomy may also be used in patients with refractory Cushing disease or with difficult-to-treat ectopic ACTH-dependent Cushing syndrome.

COMPLICATIONS

- After TSS, patients may have persistent disease or recurrence.
- Postoperative complications may include transient diabetes insipidus and syndrome of inappropriate antidiuretic hormone secretion, central hypothyroidism, growth hormone deficiency, hypogonadism, bleeding, infection (meningitis), and pituitary apoplexy.
- Patients who undergo bilateral adrenalectomy with Cushing disease must be aware of the potential of Nelson syndrome, characterized by increased pigmentation, elevated ACTH levels, and a growing pituitary ACTH-producing pituitary tumor.

ADDITIONAL TREATMENT

- Pituitary irradiation following a failed TSS will lead to remission in approximately 80% of patients, although commonly results in hypopituitarism. Newer forms of stereotactic radiotherapy are now available as options for the treatment of Cushing syndrome, including proton beam and gamma knife.
- A number of medications are available to inhibit corticosteroid biosynthesis, although none of these agents are specifically approved for use in children. These pharmacotherapies include metyrapone and ketoconazole, which may be employed in cases of refractory Cushing or when bridging the patient to definitive therapy. In addition, dopamine receptor agonists such as pasireotide and cortisol receptor antagonists, such as mifepristone, are also under clinical investigation

for use in children.

ONGOING CARE

- Following TSS in Cushing disease, patients will be transiently adrenally insufficient while the hypothalamic-pituitary-adrenal axis is recovering.
- Stress doses of cortisol are necessary in the perioperative period.
- These should be weaned relatively rapidly to a physiologic replacement dose.
- The patient should be followed every few months, and the adrenocortical function should be periodically assessed with a 1-hour 250 mcg ACTH test. Most patients recover HPA function within 1 year after TSS.
- Following bilateral adrenalectomy, lifetime replacement glucocorticoids and mineralocorticoids, (fludrocortisone 0.1–0.3 mg daily) is required.
- All patients status post cure of Cushing need to be taught precautions for adrenal insufficiency, including emergency injection of hydrocortisone and medical alert bracelet.

ALERT

- Falsely high urine free cortisol may be obtained because of stress, obesity, pregnancy, chronic exercise, depression, poor diabetes control, alcoholism, anorexia, narcotic withdrawal, anxiety, malnutrition, and high water intake. A combined dexamethasone–CRH test may help to differentiate pseudo-Cushing syndrome from true Cushing syndrome.
- Falsely low urine free cortisol may be present if inadequate collection or intermittent cortisol hypersecretion.

CODES

ICD10

- E24.9 Cushing's syndrome, unspecified
- E24.0 Pituitary-dependent Cushing's disease
- E24.2 Drug-induced Cushing's syndrome

FAQ

- Q: What clinical clue is most useful to determine which children have obesity alone versus those with Cushing syndrome?
- A: Cushing syndrome is associated with growth failure, whereas obesity is associated with adequate linear growth.
- Q: Are most patients on lifetime glucocorticoid replacement after surgery for Cushing disease?
- A: No. The majority of patients recover their hypothalamic-pituitary-adrenal axis within 1 year of their TSS and can be weaned off glucocorticoids.

CUTANEOUS LARVA MIGRANS

Ross Newman • Jason Newland

BASICS

DESCRIPTION

Infestation of the epidermis by the infectious larvae of certain nematodes, classically manifesting with an intensely pruritic, serpiginous skin lesion

EPIDEMIOLOGY

Worldwide distribution, but most frequent in warmer climates, including the Caribbean, Africa, South America, Southeast Asia, and southeastern United States

RISK FACTORS

- Contracted from soil contaminated with dog and cat feces
- Occupational exposures occur from crawling under buildings, such as among plumbers and pipefitters.

PATHOPHYSIOLOGY

- Route of spread
 - Primary host (dog or cat) passes eggs to ground through feces.
 - Warm, sandy soil acts as an incubator.
 - Eggs mature into rhabditiform larvae (noninfectious), which molt in 5 days to filariform larvae (infectious).
- Humans are accidental hosts.
- Filariform larvae penetrate the epidermis either through hair follicles or fissures or through intact skin with the use of proteases.
- Larvae are unable to penetrate the basement membrane of the dermis; therefore, the infection remains limited to the epidermis.
- Larvae cannot complete their life cycle in the human host and die within weeks to months.
- Symptoms are due to hypersensitivity to the organism or its excreta.

ETIOLOGY

- Most common organism is the dog or cat hookworm, *Ancylostoma*

braziliense.

- Other species include *Ancylostoma caninum*, *Uncinaria stenocephala*, and *Bunostomum phlebotomum*.

DIAGNOSIS

- Diagnosis is usually clinical. Organisms are rarely recovered from biopsy and antibody titers are unreliable.

HISTORY

- Incubation period
 - Usual time from infectious exposure to symptoms is 7–10 days but may last for up to several months.
- Rash
 - Intensely pruritic, raised, serpiginous, and linear
 - Most commonly located on feet, buttocks, and abdomen; also found on face, extremities, and genitalia
- Pruritus
 - Symptoms typically begin with some tingling in the affected area with the development of the typical rash with intense pruritus.
- Speed at which rash spreads
 - Rash typically lengthens by a few millimeters to 2–3 cm daily.
- Source of infection
 - History of contact with beaches in tropical countries where dogs are frequently found
 - In the United States: most frequently contracted from moist soil in southeastern United States contaminated with animal feces

PHYSICAL EXAM

The classic rash is described as an erythematous, raised, serpiginous rash. In addition, it may begin as vesicular and/or form bullae along the track. Tracks under the skin reflect the course of the larvae. The active end is not part of the track.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Biopsy: not indicated because it rarely yields organisms
- Serologic testing: not helpful and unreliable, as immunity does not usually develop
- Diagnosis is based on clinical presentation.

DIFFERENTIAL DIAGNOSIS

- Cutaneous larva migrans should be considered in anyone with an intensely pruritic, raised, serpiginous, linear cutaneous eruption.
- Hookworm infections
 - *Strongyloides stercoralis*
 - *U. stenocephala*
 - *B. phlebotomum*
 - *Gnathostoma spinigerum*
- Free-living nematodes (*Pelodera strongyloides*) and insect larvae
- Other cutaneous eruptions that may mimic cutaneous larva migrans include the following:
 - Scabies
 - Tinea pedis
 - Erythema migrans of Lyme disease
 - Jelly fish stings
 - Contact dermatitis
 - Photosensitivity

TREATMENT

GENERAL MEASURES

- Albendazole
 - First line
 - Administered as 400 mg PO once a day for 3 days
- Ivermectin
 - 200 mcg/kg once a day for 1–2 days
 - Oral ivermectin is contraindicated in children who weigh less than 15 kg or are younger than 5 years old.
- Alternative: topical thiabendazole 10–15% applied three times a day for 5–7 days; not readily available for prescription

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Symptoms persist for 8 weeks but up to 1 year in untreated patients.
- Those with extensive involvement should be seen after treatment to be certain of improvement in symptoms.

PROGNOSIS

- This is a self-limited disease and will resolve without treatment when the larvae die.
- Cure rates with oral ivermectin range from 77 to 100% after one dose, with a second dose usually providing complete resolution. Oral albendazole for 5–7 days has cure rates of 92–100%.

COMPLICATIONS

- Most common complication is secondary bacterial infection of the involved skin.
- Self-limited disease: If untreated, larvae die within 2–8 weeks but may persist for up to 1 year.
- Rarely, the larvae can invade the dermis and, subsequently, the bloodstream, leading to a peripheral eosinophilia and pulmonary infiltrates (Löffler syndrome).

CODES

ICD10

- B76.9 Hookworm disease, unspecified
- B76.8 Other hookworm diseases

FAQ

- Q: Can children spread the infection to each other?
- A: The usual spread of infection is from direct contact with the larvae. Person-to-person spread does not occur.
- Q: What is the role of treatment in cutaneous larva migrans?
- A: Although the infestation is self-limited, as the larvae die with time, antiparasitic therapy helps to control the symptoms and prevent complications such as secondary bacterial infection.
- Q: What are preventive strategies for avoiding cutaneous larva migrans when visiting tropical beaches?
- A: When on tropical beaches frequented by dogs, wear shoes, avoid lying directly on dry sand, and only lie in sand that has been washed by the tide.
- Q: What are other names for cutaneous larva migrans?
- A: Creeping eruption, sandworms, and plumber's itch

CYCLIC VOMITING SYNDROME

Desale Yacob

BASICS

DESCRIPTION

- Cyclic vomiting syndrome (CVS) is an idiopathic disorder characterized by recurrent, stereotypical episodes of vomiting with intervening periods of normal health.
- Essential clinical features of CVS are 3 or more discrete episodes of vomiting; intervals of completely normal health between episodes; stereotypical episodes with regard to timing of onset, symptoms, and duration; as well as the absence of an identifiable organic cause for vomiting.

EPIDEMIOLOGY

- CVS commonly starts in early childhood.
- Prevalence of 1.9–2.3% has been reported.
- The syndrome is more common in Caucasians.

COMMONLY ASSOCIATED CONDITIONS

- 2/3 of CVS patients have symptoms of IBS.
- 11% of CVS patients have migraine headaches and a third of patients later develop migraine headaches.

DIAGNOSIS

- A consensus statement by the North American Society for Pediatric Gastroenterology, Hepatology and Nutrition (NASPGHAN) expert task force suggests the diagnosis can be made if the following criteria are met:
 - A minimum of 3 attacks during a 6-month period or at least 5 attacks in any interval
 - Episodic attacks of intense nausea and vomiting lasting 1 hour to 10 days and occurring at least 1 week apart

- Stereotypical pattern and symptoms in the individual patient
- Vomiting during attacks occurs at least 4 times/h for at least 1 hour.
- Return to baseline health between episodes
- Not attributed to another disorder
- If the above criteria is met, the diagnosis should be considered most likely to be CVS and the workup should consist of the following tests only:
 - Electrolytes, glucose, BUN, and creatinine
 - A UGI series to evaluate for malrotation
- Red flags that CVS is not the correct diagnosis include the following:
 - Episode of vomiting is characterized by the presence of the following:
 - Bilious emesis
 - Severe abdominal pain or tenderness
 - Hematemesis
- If episodes are triggered by intercurrent illness, fasting, or high-protein meal, the following labs should be obtained at the beginning of the attack prior to IV fluid:
 - Glucose, electrolytes for anion gap, urine ketones serum lactate, ammonia and amino acids, urine organic acids. Optional metabolic labs include plasma carnitine and acylcarnitine.
- If episodes occur in the context of an abnormal neurologic exam including severe altered mental status, papilledema, abnormal eye movements, motor asymmetry, and gait abnormality, consultation with a neurologist is indicated and a brain MRI should be obtained.
 - Consider at any given time:
 - US of abdomen and pelvis
 - UGI series
 - Amylase and lipase
 - Esophagogastroduodenoscopy
 - During an attack, obtain LFTs, lipase \pm amylase.

HISTORY

- Children with CVS experience a stereotypical pattern of vomiting characterized by a consistent time of onset, duration, and associated symptoms.

- Vomiting frequency is high, with median of 6 bouts of emesis per hour, often bilious and associated with severe nausea.
- The intense vomiting results in dehydration and need for IV hydration.
- Accompanying symptoms include nausea, retching, headache, abdominal pain, pallor, listlessness, anorexia, and photophobia.
- Physical and psychological stresses are common triggers.
- CVS episodes are most likely to start in the early morning hours.

PHYSICAL EXAM

Physical exam is often consistent with dehydration, and young children may appear listless.

DIAGNOSTIC TESTS & INTERPRETATION

The consideration of established criteria is important when diagnosing CVS, as is a thorough workup to rule out other etiologies that may explain the symptoms. These tests may include blood, urine, and imaging studies depending on the history and physical exam of the individual child.

Lab

- Basic metabolic panel: Na^+ , K^+ , Cl^- , HCO_3^- , glucose, BUN, and creatinine
- Liver and pancreas: ALT, GGT, lipase \pm amylase
- Other: urine ketones, lactate, ammonia, serum amino acids, urine organic acids, plasma carnitine, and acylcarnitine

Imaging

- UGI series
 - A UGI should be performed in all patients who present with bilious emesis and who are suspected to have CVS.
- Abdominal US
 - Helpful in evaluation of the hepatobiliary and urinary systems
- Brain MRI
 - Should be obtained when episodes of emesis are associated with progressive or acute, as well as diffuse or focal, neurologic symptoms or signs
 - MRI, rather than CT or skull x-ray is the preferred modality for visualization of the posterior fossa.

DIAGNOSTIC PROCEDURES/SURGERY

Esophagogastroduodenoscopy

- May be indicated if hematemesis occurs following multiple episodes of emesis in a patient with CVS
- Most likely etiologies of hematemesis in a child with CVS are mild esophagitis, Mallory-Weiss tear, or prolapse gastropathy.
- Endoscopy may also be indicated if patients have persistent symptoms between episodes suggestive of peptic/bacterial, allergic, inflammatory or celiac disease, or hematemesis of large quantity that may require endoscopic hemostasis.

DIFFERENTIAL DIAGNOSIS

- Malrotation
- UPJ obstruction
- Rumination syndrome
- Gastroparesis
- Pseudoobstruction
- CNS lesion
- Increased intracranial pressure
- Infectious illness
- Pancreatitis
- Mitochondrial disorder
- Cannabinoid hyperemesis syndrome

TREATMENT

- The treatment strategy should be tailored to an individual taking into account the following:
 - The frequency and severity of attacks as well as how badly it impacts the patient
 - Potential side effects of the treatment have to also be taken into consideration.
- Treatment of children with CVS can be as follows:
 - Prophylactic or preventive measures
 - Abortive and supportive interventions

GENERAL MEASURES

There are a number of lifestyle changes that can be implemented that may prevent recurrence of CVS attacks without resorting to daily medications. Targeted lifestyle changes that can be effective are best found by reviewing a detailed vomiting diary to identify triggers for episodes.

Generally speaking, the following are effective measures:

- Reassurance and education of patients and their families about CVS to decrease stress
- Avoidance of triggers and precipitating factors, including prolonged fasting, poor sleep hygiene, chocolate, cheese, monosodium glutamate, antigenic foods, and excessive exercise
- If episodes are induced by fasting, the child should have supplemental carbohydrate by having snacks between meals, before exertion, or at bedtime.
- Considering CVS to be in the migraine spectrum, migraine headache lifestyle interventions by doing regular aerobic exercise, regular meal times, and regulated consumption of caffeine

MEDICATIONS

- Children >5 years of age
 - Amitriptyline, a tricyclic antidepressant (TCA), has been shown to be very effective.
 - ▢ It is recommended to initially prescribe a dose of 0.25–0.5 mg/kg PO at bed time.
 - ▢ Doses should be increased by 5–10 mg weekly to a maximum dose of 1–1.5 mg/kg if symptoms continue to occur.
 - ▢ Patients should be evaluated prior to starting amitriptyline with an EKG for QT_c abnormality and 10 days after achieving peak dose.
 - ▢ Side effects of this drug consist of arrhythmia (prolongation of the QT interval), sedation, behavioral changes, and constipation.
 - ▢ Nortriptyline is another TCA that can be used as an alternative.
 - Propranolol, a β -blocker, is considered a 2nd-line therapy.
 - ▢ This should be dosed at 0.25–1 mg/kg/day PO, with a typical maximum dose of 10 mg b.i.d. or t.i.d.
 - ▢ Heart rate should be monitored and maintained ≥ 60 bpm.

- Side effects include lethargy and reduced exercise intolerance.
 - Propranolol is contraindicated in children with asthma, diabetes, heart disease, and depression. Propranolol must be tapered for 1–2 weeks when it is discontinued.
- Children 5 years of age or younger can be treated by the following:
 - Cyproheptadine, which is an antihistamine, is first choice.
 - Dosed at 0.25–0.5 mg/kg/day PO divided b.i.d. or t.i.d., the β -blocker propranolol can be used as a second choice as discussed above.
 - Nutritional supplements including the following:
 - L-carnitine 50–100 mg/kg/day PO divided b.i.d. or t.i.d. (Side effects reported include diarrhea and fishy body odor.)
 - Coenzyme Q₁₀ 10 mg/kg/day PO divided b.i.d. or t.i.d. (max 100 mg t.i.d.)
 - Other medications and supplements that have been used in treating CVS in a prophylactic measure include the following and are generally only prescribed by neurologists: phenobarbital or alternative anticonvulsants; topiramate, valproic acid, gabapentin, levetiracetam.
- A plan that combines lifestyle changes and medications with careful attention to dosing, side effects, and specialist referrals should be put in place and clearly communicated with the patients and parents.

ADDITIONAL THERAPIES

When children with CVS have an acute episode, they will require both supportive and abortive interventions.

- Decreasing stimulation by situating the patient in a quiet and dark area
- Providing fluid replacements with electrolytes and calories along with antiemetics and analgesics
- Identifying possible metabolic decompensation by paying attention to the following:
 - Anion gap, lactic acidosis, and hyperglycemia
 - Using fluids with higher dextrose concentration such as 10% may also be very helpful.
- Abortive intervention
 - Sumatriptan, an antimigraine drug, can be given at the time of onset

at a dose of 20 mg intranasally.

- Possible side effects: neck pain or burning and coronary vasospasm
- A contraindication for its use is comorbidity with basilar artery migraines.
- Supportive care
 - Fluids: D10 1/2 NS with or without KCl at 1 1/2 times maintenance
 - Peripheral parenteral nutrition may be necessary if the patient had no enteral intake for 3–5 days.
 - Antiemetic
 - Ondansetron at a dose of 0.15 mg/kg/dose (max dose: 16 mg) IV given every 4–6 hours
 - Sedatives
 - Diphenhydramine 1–1.25 mg/kg/dose (max dose: 50 mg) IV every 6 hours
 - Lorazepam 0.05–0.1 mg/kg/dose (max dose: 2 mg) IV every 6 hours
 - Analgesics
 - Ketorolac 0.4–1 mg/kg IV every 6 hours with a max dose of 30 mg and total daily max of 120 mg. Do not exceed 3–5 days of continuous use.
 - It is also important to treat any abdominal pain, diarrhea, hypertension, and complications that may result from the persistent emesis such as dehydration, weight loss, hematemesis, metabolic acidosis, and syndrome of inappropriate antidiuretic syndrome (SIADH).
 - Once the episode of emesis is over, the child can be fed ad libitum.

FOLLOW-UP RECOMMENDATIONS

Referral to either pediatric gastroenterologists or neurologists with special interest in CVS should be made.

CODES

ICD10

- G43.A0 Cyclical vomiting, not intractable
- G43.A1 Cyclical vomiting, intractable

FAQ

- Q: How should I evaluate a child with presumed CVS who presents with progressive or focal neurologic findings?
- A: The child should be evaluated for increased intracranial pressure, as well as a metabolic disorder.
- Q: How can one distinguish true encephalopathy from CVS-associated listlessness in child presenting to the ED?

- A: The child with CVS will respond to commands appropriately and is oriented despite the desire to remain low key due to the severe nausea. In contrast, a child with metabolic encephalopathy is most likely to be confused, disoriented, and difficult to arouse.

CYCLOSPORA

Jessica Newman • Jason Newland

BASICS

DESCRIPTION

Cyclospora cayetanensis, a coccidian protozoan, causes a diarrheal illness first described in humans in 1979.

GENERAL PREVENTION

Fresh produce, especially raspberries, cilantro, and salad mixes, should be washed thoroughly before being eaten, although this still may not entirely eliminate the risk of transmission.

EPIDEMIOLOGY

- Worldwide distribution, with areas of endemic infection (Nepal, Peru, Haiti, Guatemala, Indonesia)
- People living in endemic areas have a shorter illness or may be asymptomatic carriers.
- *Cyclospora* can be an opportunistic infection in human immunodeficiency virus patients.
- In the United States, infection occurs primarily in spring and summer.
- In the United States and Canada, cases are associated with consumption of imported fresh produce.

PATHOPHYSIOLOGY

- Infected patients excrete noninfectious unsporulated oocysts in their stool.
- Sporulation then occurs days to weeks after release into the environment.
- Ingestion of sporulated oocysts occurs and sporozoites are released that invade the intestinal epithelial cells.
- Sporozoites develop into trophozoites, which undergo schizogony and form merozoites.
- Merozoites may develop into macro- or microgametes, which become

fertilized, resulting in oocysts.

- Entire life cycle is completed in the host.
- Incubation period is between 2 and 14 days, with an average of 7 days.

ETIOLOGY

- Outbreaks have been associated with the consumption of raspberries, mesclun (young salad greens), salad mixes, cilantro, and basil.
- Infection occurs through the consumption of contaminated food and water.
- Transmission does not occur through person-to-person spread.

DIAGNOSIS

HISTORY

- Fever
 - Low-grade fever is common.
- Clinical prodrome
 - Acute onset of diarrhea is typical, but a flulike prodrome may occur.
- Nature of the diarrhea
 - Profuse, nonbloody, watery diarrhea that may be foul smelling
 - Can alternate with constipation
- Other symptoms experienced:
 - Abdominal cramping
 - Fatigue
 - Anorexia
 - Flatulence
 - Vomiting
- Foods that have been consumed in the past 2 weeks
 - Illness has been attributed to contaminated raspberries, water, mesclun, salad mix, cilantro, and basil.

PHYSICAL EXAM

Dehydration

- Due to profuse diarrhea, signs of dehydration (tachycardia, dry mucous membranes, sunken eyes, poor skin turgor, and weight loss) may be present.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Ova and parasites with modified acid-fast staining
 - Identification of Cyclospora, Isospora, and Cryptosporidium
 - Three samples are preferable due to intermittent shedding.
- PCR testing is available from the CDC.
- Ova and parasites: identify common protozoans including Giardia
- Cryptosporidium and Giardia antigen test: immunoassay with high sensitivity and specificity
- Electron microscopy of stool: gold standard for diagnosing microsporidia
- Bacterial stool cultures: identify common bacterial pathogens
- Stool for Clostridium difficile PCR: identify a common cause of diarrhea
- Electrolytes, blood urea nitrogen, creatinine: determine extent of dehydration

DIFFERENTIAL DIAGNOSIS

- Cryptosporidium
 - Outbreaks are associated with contaminated water sources (municipal pools).
 - Person-to-person transmission may occur.
 - Clinically indistinguishable from Cyclospora
- Isospora belli
 - Outbreaks are associated with food and water.
 - Clinically indistinguishable from Cyclospora, although fever may be more common
- Microsporidia
 - Outbreaks are associated with contaminated water sources.
 - Chronic diarrhea occurs in immunocompromised patients, especially HIV patients.
 - Fever is uncommon.
- Giardia lamblia
 - Community epidemics are associated primarily with contaminated water sources.
 - Person-to-person transmission may occur and has led to outbreaks

in day care centers.

- Clinical presentation may vary from occasional acute watery diarrhea to a severe, protracted diarrheal illness.
- Viral gastroenteritis
 - Rotavirus
 - Adenovirus
- Bacterial gastroenteritis
 - *C. difficile*
 - *Vibrio cholerae* and non-*cholerae* *Vibrio* species
 - *Escherichia coli* (especially toxin-producing strains)
 - *Shigella* species
 - *Salmonella* species
 - *Yersinia enterocolitica*
 - *Campylobacter* species

TREATMENT

MEDICATIONS

- Immunocompetent patient: trimethoprim (5 mg/kg)-sulfamethoxazole IV/PO twice a day for 7–10 days
- HIV patient: trimethoprim-sulfamethoxazole 3 times a day for 10 days and then prophylactic dosing 3 times per week to prevent relapse
- Ciprofloxacin or nitazoxanide for 7 days may be alternatives in patients with sulfa allergy.
- Based on severity of dehydration, treatment with IV fluids may be indicated.

INPATIENT CONSIDERATIONS

Admission Criteria

Moderate to severe dehydration

ONGOING CARE

PROGNOSIS

- Most cases are self-limited.

- Diarrhea may last up to 3 months in untreated patients who acquired the parasite in a foreign country where *Cyclospora* is endemic.
- In U.S. outbreaks, the average duration of diarrhea ranged from 10 to 24 days.
- Relapses may occur in untreated patients.
- Patients with HIV have more severe and prolonged diarrhea, which may recur.

COMPLICATIONS

- Dehydration and weight loss are the most common complications.
 - Severe, prolonged diarrhea may lead to dehydration.
 - Malabsorption of D-xylose and excretion of fecal fat occurs, leading to weight loss.
- May cause ascending biliary tract disease in AIDS patients
- Rare associated complications
 - Guillain-Barré syndrome
 - Reactive arthritis

PATIENT MONITORING

- Infected patients need to be observed closely for dehydration.
- Relapse may occur in HIV patients, so close follow-up is essential.

CODES

ICD10

A07.4 Cyclosporiasis

FAQ

- Q: Does routine ova and parasites testing detect Cyclospora?
- A: Rarely. Therefore, modified acid-fast staining must be done to improve the laboratory's ability to detect the oocysts.
- Q: Can person-to-person transmission occur in Cyclospora illness?
- A: No. It takes days to weeks for oocysts to sporulate and become infectious.

CYSTIC FIBROSIS

Samuel B. Goldfarb • Bruce A. Ong

BASICS

DESCRIPTION

Cystic fibrosis (CF) is an inherited autosomal recessive disorder, characterized by chronic obstructive lung disease, pancreatic exocrine insufficiency, and elevated sweat chloride concentration.

ALERT

- Most common pitfall is failure to diagnose. Neonatal screening is not performed in all states.
- Not uncommon to delay making the diagnosis in patients with mild symptoms

EPIDEMIOLOGY

- Most common lethal inherited disease in the Caucasian population
- Carrier frequency of mutations in the CF transmembrane conductance regulator (CFTR) gene:
 - 1:29 in Caucasians
 - 1:49 in Hispanics
 - 1:53 in Native Americans
 - 1:62 in African Americans
 - 1:90 in Asians

Prevalence

- 1:3,300 in Caucasians
- 1:9,500 in Hispanics
- 1:11,200 in Native Americans
- 1:15,300 in African Americans
- 1:32,100 in Asians

RISK FACTORS

Genetics

CFTR gene

- Located on the long arm of chromosome 7
- Most common mutation results in deletion of phenylalanine at position 508 in the CFTR glycoprotein.
- The $\Delta 508$ mutation occurs in ~70% of CF patients.
- >1,500 mutations have been reported in the CFTR gene.
- Presence of gene modifiers may cause incomplete phenotypic presentations.

GENERAL PREVENTION

Prepregnancy carrier detection

PATHOPHYSIOLOGY

- CFTR
 - Membrane glycoprotein, which functions as a cyclic AMP–activated chloride channel at the apical surface of epithelial cells
 - An abnormality in CFTR results in defective chloride conductance.
 - May have other roles in the regulation of membrane channels and the pH of intracellular organelles; may affect cell apical sodium channel regulation
 - CFTR abnormalities may act as binding sites for *Pseudomonas aeruginosa*, promoting proinflammatory responses in the lung.
- In the respiratory system
 - Increased mucus viscosity
 - Early bacterial colonization despite a robust neutrophilic inflammatory response
 - Mucous plugging and atelectasis
 - Bronchiectasis and emphysema develop.
 - Abnormal nasal sinus development
- In the GI tract
 - Progressive pancreatic damage leads to exocrine pancreatic insufficiency.
 - Endocrine pancreatic dysfunction
 - Focal biliary cirrhosis of the liver
 - Hypoplasia of the gallbladder and impaired bile flow

DIAGNOSIS

HISTORY

- Most common presenting respiratory symptoms: chronic cough, recurrent pneumonia, nasal polyps, chronic pansinusitis
- Most common presenting GI symptoms:
 - Meconium ileus (15–20% of patients present with this symptom); pancreatic insufficiency occurs in 85% of patients. In infants, fat malabsorption may lead to chronic diarrhea and failure to thrive.
 - In older patients, pancreatitis, rectal prolapse (occurs in 2% of the patients; must consider CF until proven otherwise)
 - Distal obstruction of the small intestine (meconium ileus equivalent, seen in older children and adults)
- Evidence of heat intolerance: In summer, increased sweating may lead to dehydration with hyponatremia or hypochloremic metabolic alkalosis.

PHYSICAL EXAM

- Respiratory findings:
 - Frequent cough, often productive of mucopurulent sputum
 - Rhonchi, crackles, wheezing, hyperresonance to percussion
 - Nasal polyposis
- Other common findings:
 - Digital clubbing
 - Hepatosplenomegaly in patients with cirrhosis
 - Growth retardation
 - Delayed puberty
 - Osteoporosis

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Sweat test: keystone for the diagnosis of CF
 - Sweat chloride >60 mEq/L is abnormal.
 - <40 mmol/L: negative
 - 40–60 mmol/L: borderline
 - >60 mmol/L: consistent with CF
 - In infants up to 6 months of age

- 30–60 mmol/L: borderline
 - 60 mmol/L: consistent with CF
- Diagnostic criteria include the following:
 - One or more phenotypic features of CF or a sibling with CF or a positive newborn screening test
- PLUS**
 - 2 positive sweat tests or 2 CF mutations on genetic screening or nasal potential difference (NPD) consistent with CF
- Other causes of elevated sweat chloride:
 - Malnutrition
 - Adrenal insufficiency
 - Nephrogenic diabetes insipidus
 - Ectodermal dysplasia
 - Fucosidosis
 - Hypogammaglobulinemia
 - False negatives seen in CF patients with edema
- Mutation analysis: can detect >90% of CF patients. Failure to identify 2 mutations reduces but does not eliminate CF diagnosis.
- Immunoreactive trypsinogen test (IRT) is used for newborn screening. Blood drawn 2–3 days after birth is analyzed for trypsinogen.
 - Positive IRT tests must be confirmed by sweat test and/or genetic testing.
 - IRT testing may be normal in the presence of meconium ileus
- Frequently recovered organisms in sputum cultures:
 - *Haemophilus influenzae*
 - *Staphylococcus aureus*
 - Methicillin-resistant *Staphylococcus aureus* (MRSA)
 - *P. aeruginosa* (nonmucoid and mucoid)
 - *Burkholderia cepacia*
 - *Stenotrophomonas maltophilia*
 - *Aspergillus* and other fungal species
 - Nontuberculous mycobacterial species
- Pulmonary function test: usually reveals obstructive lung disease, although some patients may have a restrictive pattern
- Analysis of stimulated pancreatic secretions: degree of pancreatic

exocrine deficiency

- Fecal elastase measurements can detect pancreatic insufficiency.
- 72-hour fecal fat measurement: fat malabsorption

Imaging

- Chest radiography
 - Typical features include hyperinflation, peribronchial thickening, atelectasis, and bronchiectasis.
- CT scan
 - Bronchiectasis
 - Cystic and interstitial changes
 - Focal consolidation or scarring

DIFFERENTIAL DIAGNOSIS

- Pulmonary
 - Recurrent pneumonia or bronchitis
 - Asthma
 - Aspiration pneumonia
 - Ciliary dyskinesia
 - Airway anomalies
 - Chronic sinusitis
 - Chronic aspiration
 - Non-CF bronchiectasis
 - Allergic bronchopulmonary aspergillosis
 - α_1 -Antitrypsin disease
- GI
 - Celiac disease
 - Protein-losing enteropathy
 - GERD
 - Chronic pancreatitis
- Other:
 - Metabolic alkalosis
 - Immune deficiency
 - Shwachman-Diamond syndrome

TREATMENT

MEDICATION

First Line

- Antibiotic therapy based on sputum culture results and clinical improvement:
 - Oral antibiotics:
 - Cephalexin
 - Linezolid
 - Trimethoprim-sulfamethoxazole
 - Ciprofloxacin, inhaled tobramycin, colistin, or aztreonam in selected patients
 - IV antibiotics:
 - To treat *S. aureus*, consider oxacillin, ticarcillin with clavulanic acid, linezolid, or vancomycin.
 - To treat *P. aeruginosa* and *B. cepacia*, consider aminoglycoside plus ticarcillin, ceftazidime, or piperacillin.
 - Severe cases with resistant strains may benefit from aztreonam, imipenem, or meropenem.
 - Two or more antibiotics may be used during treatment of pulmonary exacerbations.
 - The use of regular azithromycin is controversial due to emerging mycobacterial resistance.
 - Indwelling catheters may be needed for frequent antibiotic therapy
- Clearance of pulmonary secretions
 - Chest physical therapy or with high-frequency oscillatory vest device. Adjunct therapy such as flutter valve, Acapella, or PEP mask may also be used.
 - Bronchodilator: aerosol or metered-dose inhaler (β_2 -agonist)
 - Mucolytics: RhDNase
 - Anti-inflammatory: short-term oral steroid course. Inhaled corticosteroids may benefit patients with asthma and/or those demonstrating an oral steroid response.
 - Hypertonic saline
- GI disease
 - Pancreatic enzyme replacement therapy: used in CF patients who are pancreatic insufficient; dosage adjusted for frequency and

character of the stools and for growth pattern; generic substitutes are not bioequivalent to name brands. The maximum recommended dose is 2,500 U of lipase/kg per meal and 10,000 U of lipase/kg/24 h.

- Vitamin supplements: multivitamin, fat-soluble vitamins A, D, E, and K
- Salt supplementation
- Patients with cholestasis may benefit from therapy with ursodeoxycholic acid.

Other Medications

- CFTR potentiators
 - G551D mutations treated with ivacaftor will improve lung function, decrease exacerbations, and, in some cases, normalize sweat test.
 - Ongoing research is underway to determine if other CF genotypes may benefit from this targeted therapy or other therapies.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Specialized care should be at a CF center.
- Frequency of visits depends on age and severity of illness:
 - Infants should be seen at least monthly for the first 12 months, then every 2–3 months.

DIET

- High-calorie diet with added salt
- Lifelong nutritional support usually required
- Gastrostomy tube placement may be necessary to increase caloric intake and maintain growth.

Respiratory

- Throat and sputum cultures for fungi, acid-fast bacteria, and aerobic organisms are used to direct antimicrobial therapy.
- Duration of antibiotic therapy is controversial; more frequent use is required as pulmonary function deteriorates.

PROGNOSIS

- Current median survival is ~38 years.
- Variable course of the disease
- The median survival has been increasing for the past 4 decades, although the rate of increase in age has slowed in the past decade.

COMPLICATIONS

- Respiratory complications:
 - Recurrent bronchitis and pneumonia
 - Atelectasis
 - Bronchiectasis
 - Pneumothorax
 - Hemoptysis
 - Chronic sinusitis and nasal polyps
- CV complications:
 - Pulmonary hypertension in older patients
- GI complications:
 - Pancreatic insufficiency in 85–90% of CF patients
 - Patients usually have steatorrhea and poor growth and nutritional status.
 - Decreased levels of vitamins A, E, D, and K
 - Rectal prolapse
 - 10–15% of patients have meconium ileus.
 - Distal intestinal obstruction syndrome
 - Clinically significant focal biliary cirrhosis; hepatobiliary disease in 5% of CF patients
 - Esophageal varices
 - Splenomegaly
 - Hypersplenism
 - Cholestasis
- Reproductive complications:
 - Sterility in 98% of males due to absence or atresia of the vas deferens
 - Slight decrease in fertility for females secondary to abnormalities of cervical mucus

- Endocrine complications:
 - Glucose intolerance
 - CF-related diabetes occurs with increasing frequency in adolescent and adult patients.
- Skeletal complications:
 - Osteoporosis

- E84.0 Cystic fibrosis with pulmonary manifestations
- E84.11 Meconium ileus in cystic fibrosis

FAQ

- Q: Should relatives be tested?
- A: All siblings should have a sweat test.
- Q: How well will a child with CF do?
- A: The course of the illness is variable. It is difficult to predict the course of disease in an individual.
- Q: How should a borderline sweat test be interpreted?
- A: Borderline sweat tests should always be correlated with other findings such as physical exam, sputum cultures, pulmonary function, radiographic findings, nutritional evaluation, and/or mutation analysis.

CYTOMEGALOVIRUS INFECTION

Swathi Gowtham • Ravit Arav-Boger

BASICS

DESCRIPTION

Cytomegalovirus (CMV) is a ubiquitous double-stranded DNA virus that is a member of the herpesvirus family. It establishes latency in peripheral blood mononuclear cells and endothelial cells.

EPIDEMIOLOGY

- Primary infection occurs from early childhood into adolescence and childbearing years.
- Transmission occurs by contact with infected body fluids such as saliva, urine, blood, or breast milk through sexual contact or solid organ transplantation. Intrauterine transmission is the most common route of acquiring congenital infection.

Prevalence

Seroprevalence increases with age and varies with socioeconomic status; 50% of middle- and 80% of lower socioeconomic status adults are seropositive.

GENERAL PREVENTION

- Pregnant women should receive education about CMV transmission. Precautions should be instituted for hospitalized patients known to be shedding CMV.
- Seriously ill neonates should receive blood products from CMV-negative donors.
- CMV-seronegative solid organ transplantation recipients should receive organs (and all blood products) from CMV-negative donors whenever possible.
- Hyperimmunoglobulin has been used in high-risk CMV-negative recipients of CMV-positive donors to prevent severe CMV disease.

PATHOPHYSIOLOGY

Infection leads to intranuclear inclusions with massive enlargement of cells. Almost any organ may become infected with CMV in severe disseminated infection.

COMMONLY ASSOCIATED CONDITIONS

- Congenital infection
 - Occurs in about 1% of newborns in United States
 - Intrauterine transmission is more common in pregnant women mothers with primary infection during pregnancy (40–50%) compared to recurrent infection (<1%). Postnatal acquisition of CMV via breast milk: controversy exists over whether this precludes breastfeeding in premature infants (has a lower risk for neurological sequelae than congenital infection).
 - 10% of infected infants are symptomatic at birth, with severe disease characterized by growth retardation, hepatosplenomegaly, thrombocytopenia, and CNS involvement.
 - 10–20% of infants who are asymptotically infected at birth may develop hearing loss.
 - Of symptomatically infected infants, 90% will have some neurologic sequelae. Degree of impairments may be predicted by CT findings and microcephaly at birth.
- Mononucleosis syndrome
 - CMV can cause a mononucleosis-like syndrome similar to that caused by Epstein-Barr virus (EBV) infection in immunocompetent patients.
 - The most common symptoms are malaise (67%) and fever (50%). ~70% of patients have abnormal liver enzymes.
 - Pharyngitis and splenomegaly less common and severe than observed with EBV-induced mononucleosis.
- Interstitial pneumonitis
 - Seen primarily in severely immunosuppressed children and adults
 - Begins with fever and nonproductive cough but may progress to dyspnea and severe hypoxia over 1–2 weeks
 - Mild, self-limited pneumonitis may occur in immunocompetent patients.
- Retinitis

- Observed in infants with symptomatic congenital infection and in patients with advanced AIDS
- Immunosuppressed children should have regular eye exams.
- Hepatitis
 - Occurs in healthy individuals with primary infections and in immunosuppressed patients with either primary or reactivated disease
 - Fever, mild elevation of liver enzymes, and hepatomegaly are typical. Jaundice and severe hepatitis are uncommon.
- GI disease
 - Severely immunosuppressed patients may experience esophagitis, gastritis, colitis, or pancreatitis.
 - Diagnosis requires endoscopy with biopsy.
- CNS disease
 - Commonly seen in infants with symptomatic congenital infection
 - Characterized by microcephaly, periventricular calcifications, seizures, developmental delay, and sensorineural hearing loss
 - Encephalitis or meningoencephalitis may occur in immunocompromised patients and very rarely reported in literature in immunocompetent hosts.
- Hearing loss
 - Congenital CMV is the most common infectious cause of deafness.
 - Onset of deafness often seen after 1st month of life and is progressive. May be missed by newborn hearing screen (if only done in first 2 weeks of life)

DIAGNOSIS

HISTORY

Exposures

- Day care attendance
 - Increased risk of infection
- Recent blood transfusion
 - Transfusion-associated CMV
- Use of immunosuppressive medications

- Increased cause of serious infection

Symptoms

- Prolonged fever
 - Mononucleosis-like syndrome
- Blurred vision
 - CMV retinitis
- Cough, dyspnea, wheezing
 - CMV pneumonitis
- Vomiting, abdominal pain, diarrhea (watery or bloody)
 - CMV colitis

PHYSICAL EXAM

- Microcephaly
 - Congenital infection
- White, perivascular retinal infiltrates and hemorrhage
 - Retinitis
- Hearing loss (may require audiogram, brainstem evoked auditory responses)
 - Congenital infection
- Photophobia, headache, nuchal rigidity
 - Meningitis/encephalitis
- Tachypnea, rales
 - Pneumonitis
- Hepatomegaly and/or splenomegaly
 - Mononucleosis-like syndrome
- Rash
 - Petechiae, purpura, “blueberry muffin” lesions, rubelliform rash
- Adenopathy
 - Mononucleosis-like syndrome

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Shell-vial assay: (staining for immediate early antigen production) allows detection of virus 24–48 hours after inoculation
- Viral culture: Virus may be isolated from nasopharyngeal/oropharyngeal secretions, urine, stool, and WBC.

Isolation may take up to 4 weeks. Urine or saliva samples are most common way to diagnose congenital disease.

- Highly sensitive CMV quantitative polymerase chain reaction (PCR) assay: Measure viral DNA in plasma, whole blood, urine, and CSF. Real-time PCR has replaced most diagnostic tests in monitoring response to therapy or identifying viral quantitation. Recently standardized to be reported as IU/mL.
- Quantitative antigenemia assay: detection of circulating CMV-infected polymorphonuclear cells by indirect immunofluorescence. In an immunocompromised patient, may monitor response to therapy or identify viral reactivation.
- Serology: Enzyme-linked immunosorbent assay or indirect fluorescent antibody assay to detect the presence of CMV IgM, or IgG has a limited role. IgG avidity test can be used in certain circumstances, particularly in pregnant women, to diagnose a recent infection.

ALERT

- Due to frequency of asymptomatic shedding, mere isolation of virus does not necessarily establish an etiologic association.
- Severely immunocompromised patients who are actively infected with CMV may be seronegative. 4-fold rise in CMV IgG is not diagnostic of primary infection. Increased antibody titers may occur with reactivation. DNA quantification by real-time PCR is useful in these circumstances to make a timely diagnosis.

Imaging

- Noncontrast head CT
 - Periventricular calcifications, cystic abnormalities, ventriculomegaly, periventricular leukomalacia
- Brain MRI
 - Has higher sensitivity than ultrasound for brain abnormalities and greater predictor of symptomatic infection

DIFFERENTIAL DIAGNOSIS

- Congenital infection
 - Congenital rubella syndrome
 - Toxoplasmosis

- Syphilis
- Neonatal herpes simplex virus
- Human immunodeficiency virus
- Enteroviral infection
- Mononucleosis syndrome
 - EBV infection
 - Toxoplasmosis
 - Hepatitis A or B infection
- Interstitial pneumonitis
 - Respiratory syncytial virus
 - Adenovirus
 - Measles
 - Varicella
 - Pneumocystis jiroveci (previously carinii)
 - Chlamydia
 - Mycoplasma
 - Fungal
 - Drug/toxin-induced pneumonitis
- Retinitis
 - Ocular toxoplasmosis
 - Candidal retinitis
 - Syphilis
 - Herpes simplex virus
- Hepatitis
 - EBV infection
 - Hepatitis A, B, or C infection
 - Enterovirus
 - Adenovirus
 - Herpes simplex virus
 - Drug/toxin-induced
- GI disease
 - Herpes simplex virus
 - Adenovirus
 - Salmonella
 - Shigella

- Campylobacter
- Yersinia
- Clostridium difficile
- Giardia
- Cryptosporidium
- CNS disease
 - Congenital disease (see [congenital infection](#) earlier)
 - Meningoencephalitis in immunocompetent host: herpes simplex virus, EBV, varicella-zoster virus, enterovirus, arbovirus
- Meningoencephalitis in immunocompromised host: in addition to organisms listed previously, should include HIV encephalitis, fungal meningitis, toxoplasmosis

TREATMENT

Majority of transplant experts prefer prophylaxis over preemptive therapy in high-risk patients (donor CMV positive, recipient negative).

MEDICATION

First Line

- Ganciclovir: suppresses viral replication by inhibiting the viral DNA polymerase
 - Indications: symptomatic congenital CMV in a neonate meeting clinical criteria; CMV chorioretinitis in immunocompromised patients; tissue diagnosis (hepatitis, enteritis, pneumonitis) of CMV infection; and in immunocompromised patients with CMV disease (viremia + symptoms)
 - Side effects: neutropenia (60%), thrombocytopenia (~5%)
- Foscarnet: suppresses viral replication by inhibiting viral DNA polymerase
 - Indications: same as earlier, but in patients who have failed to improve on ganciclovir therapy or who has experienced significant bone marrow toxicity related to ganciclovir use or with resistance to ganciclovir
 - Side effects: renal impairment (12–33%), headache (26%), seizures

(10%)

ONGOING CARE

PROGNOSIS

Varies with nature of infection (see “[Commonly Associated Conditions](#)”)

COMPLICATIONS

Varies with nature of infection (see “[Commonly Associated Conditions](#)”)

CODES

ICD10

- B25.9 Cytomegaloviral disease, unspecified
- P35.1 Congenital cytomegalovirus infection
- B25.0 Cytomegaloviral pneumonitis

FAQ

- Q: Should children with congenital CMV infection be excluded from day care settings?
- A: No. Due to the high frequency of shedding of CMV in the urine and saliva of asymptomatic children, especially those younger than 2 years of age, exclusion from out-of-home care is not justified for any child known to be infected with CMV. Careful attention to hygienic practices, especially hand washing, is important.

DAYTIME INCONTINENCE

Amanda K. Berry • Michael C. Carr

BASICS

DESCRIPTION

- Daytime wetting in a child ≥ 5 years of age warrants evaluation.
- Causes of functional incontinence include an array of bladder storage and voiding disorders.
- Voiding dysfunction is abnormal behavior of the lower urinary tract without a recognized organic cause, generally in the form of pelvic floor hyperactivity or bladder–sphincter discoordination.
- Dysfunctional elimination syndrome describes the association between abnormal bladder and bowel behavior.

Prevalence

- Studies in children 6–7 years of age have shown that 3.1% of girls and 2.1% of boys had an episode of wetting at least once per week.
- Spontaneous cure rate of 14% per year without treatment
- Of all children who wet, 10% have only daytime wetting, 75% wet only at night, and 15% wet during the day and at night.

RISK FACTORS

- Constipation
- Recurrent urinary tract infections (UTIs)
- Diabetes mellitus/diabetes insipidus
- Attention-deficit disorder/attention-deficit/hyperactivity disorder (ADD/ADHD)
- Developmental delay

Genetics

- Only anecdotal relationships have been seen in functional daytime incontinence, unlike studies showing genetic tendencies in nocturnal enuresis.
- Increased rates of daytime wetting have been reported in urofacial (Ochoa) syndrome, an autosomal recessive condition, and Williams

syndrome, which is the result of a deletion involving the elastin gene in chromosome 7.

ETIOLOGY

- Neurogenic bladder (e.g., myelomeningocele)
- Anatomic anomalies (e.g., ectopic ureter)
- Obstructive uropathy (e.g., posterior urethral valves)
- Bladder irritability caused by UTI
- Constipation
- Increased urinary output—polyuria
- Infrequent or deferred voiding
- Overactive bladder
- Low functional bladder capacity, with detrusor instability during filling
- Vaginal reflux
- Giggle incontinence
- Temperamental factors (e.g., short attention span, inattentiveness to body signals) in children who ignore the urge to void
- Developmental differences in age at which toilet training is achieved

COMMONLY ASSOCIATED CONDITIONS

- Constipation (common)
- Nocturnal enuresis (common)
- UTIs (common)
- Vesicoureteral reflux is more common in children with voiding dysfunction due to elevated detrusor pressures that overcome a marginal vesicoureteral junction.

DIAGNOSIS

SIGNS AND SYMPTOMS

- Urgency
 - Posturing, Vincent curtsy
- Frequent urination
- Deferred voiding
- Weak or intermittent stream
- Large, hard, or infrequently passed bowel movements

- Recurrent UTIs

HISTORY

- Onset (primary vs. secondary)
- Frequency of voiding
- Frequency and degree of wetting
- Presence or absence of any dry interval
- Signs of urgency, use of hold maneuvers, waiting until the last minute to void
- Description of stream (i.e., strong/weak, continuous/interrupted)
- Straining or pushing during voiding
- Frequency and description of bowel movements
- Presence or history of fecal soiling
- Quality and quantity of fluid intake
- History of UTIs, vesicoureteral reflux
- ADD/ADHD, learning disabilities, or developmental delays
- Level of concern on part of child/family
- Medications

PHYSICAL EXAM

- Abdomen: signs of constipation, distended bladder
- Rectal: if constipation is suspected
- Spine: sacral abnormalities
- Genitalia: labial adhesions, labial erythema, phimosis, urethral stenosis, evidence of leakage
- Neurologic: sensation, reflexes, and gait

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- 1st morning urinalysis to check concentrating ability, rule out occult renal disease
- Urine culture to rule out infection

Imaging

- Renal and bladder ultrasound in children who wet with a history of UTIs and in children with persistent wetting despite regular voiding
- Kidneys, ureter, and bladder (KUB) x-ray to assess for constipation

- MRI of lumbosacral spine if sacral abnormality or refractory to treatment

Diagnostic Procedures/Other

- Uroflowmetry and assessment of postvoid residual urine
- Invasive urodynamic testing is not indicated in neurologically normal children unless refractory to treatment.

DIFFERENTIAL DIAGNOSIS

- UTI
- Constipation
- Developmental variations in toilet training
- Neurogenic bladder
- Spinal cord abnormality
- Giggle incontinence
- Stress incontinence
- Genitourinary tract abnormality (posterior urethral valve, ectopic ureter)
- Vaginal reflux
- Benign increased urinary frequency (pollakiuria)
- Sexual abuse

TREATMENT

GENERAL MEASURES

- Aggressive management of bowels so that child is passing at least 1 soft bowel movement daily (see “[Constipation](#)”)
- Elimination schedule, with voids every 2–3 hours and time to defecate at least once a day. A reminder watch may be helpful.
- Voiding diary provides concrete data and focus for child.
- Positive reinforcement for regular voiding
- Avoid acidic/diuretic beverages (caffeine, carbonation, chocolate, citrus).
- Adequate hydration
- Local management of perineal irritation/vulvovaginitis to ensure comfort during voiding

- Girls with postvoid dribbling due to vaginal reflux should void with their legs wide apart, sitting backward on the toilet when possible, to minimize backflow of urine into the vagina. Wipe after standing up.

ALERT

- Failure to recognize and manage constipation before attempting to manage wetting
- Use of anticholinergic medications in children with benign frequency of childhood is generally ineffective.
- Increased risk of UTIs when child is placed on anticholinergic medication due to infrequent voiding/incomplete emptying

MEDICATION

- A trial of an anticholinergic may be indicated if the child wets despite conservative medical/behavioral management.
- Extended-release formulations are available.
- Common side effects include dry mouth, decreased diaphoresis with flushing, and constipation. Blurred vision and dizziness are less common.

First Line (≥ 5 years old)

- Oxybutynin (Ditropan/Ditropan XL): 5–15 mg/24 h
- Tolterodine (Detrol/Detrol LA): 2–4 mg/24 h (adult dose; pediatric dose not established)
- Solifenacin (Vesicare): 5–10 mg/24 h (adult dose; pediatric dose not established)

ADDITIONAL TREATMENT

Pelvic floor muscle retraining through biofeedback can help children learn to identify and relax the pelvic floor muscles to empty the bladder smoothly and completely.

ISSUES FOR REFERRAL

Referral to pediatric urologist

- When wetting is accompanied by recurrent UTIs
- When wetting is refractory to behavioral management, child may benefit from a noninvasive urodynamic evaluation to assess flow pattern, voiding mechanics, and ability to empty the bladder.

ONGOING CARE

PROGNOSIS

- Spontaneous cure rate of 14% per year without treatment
- 72% of patients sustained improvement 1 year after simple behavioral therapy.

COMPLICATIONS

- Local irritation and inflammation of the perineum
- Functional daytime incontinence is primarily a social problem that affects children's self-esteem and interactions with peers.

CODES

ICD10

- R32 Unspecified urinary incontinence
- N39.498 Other specified urinary incontinence

FAQ

- Q: What findings can distinguish functional incontinence from an ectopic ureter?
- A: An ectopic ureter in girls usually empties below the sphincter or elsewhere, such as in the vagina. Therefore, these girls wet all the time, with no dry period. They do not have symptoms such as urgency. Because in most cases the ureter draining the kidney is duplicated, an ultrasound may be obtained but is not always diagnostic. MR urography provides superior imaging of the urinary tract and is useful in diagnosing ectopic ureter.
- Q: What is a normal bladder capacity for a child?
- A: Normal bladder capacity (in ounces) can be estimated as the child's age plus 1 oz. A child's bladder capacity can be determined by measuring voided volumes for 2 consecutive days when the child is well hydrated. The largest voided volume (not including the first morning void) is considered the child's functional capacity.
- Q: How much water should a child drink each day to cycle the bladder well?
- Adequate water drinking is important to keep the urine more dilute and less irritating to the bladder and to help cycle the bladder. In addition to other fluids, children 5–7 years old should drink at least 20–28 oz of water/day, children 8–12 years old should drink 28–32 oz of water/day, and teens should drink 36–48 oz of water/day.

DEHYDRATION

Marc H. Gorelick

BASICS

DESCRIPTION

- Dehydration is a negative balance of body fluid, usually expressed as a percentage of body weight. Mild, moderate, and severe dehydration correspond to deficits of <5%, 5–10%, and >10%, respectively.
- Dehydration is classified into 3 types on the basis of serum sodium concentration: isotonic (Na 130–150 mmol/L), hypotonic (Na <130 mmol/L), and hypertonic (Na >150 mmol/L).

GENERAL PREVENTION

Many cases of frank dehydration may be prevented by early institution of adequate oral maintenance fluid therapy in children with gastroenteritis, with particular attention to replacement of ongoing stool losses and slow administration of fluids to children with vomiting. Use of appropriate solutions is essential to prevent electrolyte disturbance and worsening of diarrhea.

EPIDEMIOLOGY

- ~10% of children in the United States with acute gastroenteritis develop at least mild dehydration.
- Although it accounts for 10% of all nonsurgical hospital admissions for children younger than 5 years of age, up to 90% of cases can be managed on an outpatient basis.
- Incidence of moderate to severe dehydration has declined since the introduction of routine rotavirus immunization

PATHOPHYSIOLOGY

- Dehydration is caused by either excessive fluid losses or inadequate intake of fluids.
- Some conditions leading to dehydration include the following:
 - GI losses: vomiting, diarrhea (most common cause of dehydration)

in pediatric patients)

- Renal losses: diabetes mellitus, diabetes insipidus, diuretic agents
- Insensible losses: sweating, fever, tachypnea, increased ambient temperature, large burns
- Poor oral intake: stomatitis, pharyngitis, anorexia, oral trauma, altered mental status
- Note that infants and debilitated patients are at particular risk due to lack of ability to satisfy their thirst freely.

DIAGNOSIS

HISTORY

- Frequency and duration of emesis and/or diarrhea gives an estimate of risk of dehydration.
- If there were large quantities of water taken, be alert for hypotonic dehydration. If inadequate free water is used for hydration, patient may have hypertonic dehydration.
- Frequency and quantity of urination may be difficult to estimate in infants with diarrhea.
- Decreased urination indicates possibility of dehydration but is nonspecific.
- Fever increases insensible water loss.
- Exertion or heat exposure increases insensible water loss.

PHYSICAL EXAM

- Acute change in weight is the best indicator of fluid deficit. If the child's recent preillness weight is not available for comparison, a reasonable estimate of the degree of dehydration may be made from physical findings (see [Appendix, Table 2](#)).
- General appearance: lethargy, irritability, thirst
- Vital signs: tachycardia, orthostatic increase in heart rate or hypotension, hyperpnea
- Skin: Prolonged capillary refill at fingertip (<2 seconds is normal in warm environment), mottling, poor turgor
- Eyes: decreased or absent tears, sunken eyes

- Mucous membranes: dry or parched
- Anterior fontanelle: sunken

ALERT

Diagnostic pitfalls

- Physical signs generally appear when the deficit is as small as 2%.
- No single finding is pathognomonic of dehydration. A reasonable guideline is that the presence of 3 or more findings indicates at least mild dehydration. The number and severity of physical signs increase with the degree of dehydration.
- Urine output decreases early in the course of dehydration, and a history of decreased urination is a sensitive but nonspecific finding.
- Capillary refill time is a specific but insensitive indicator. It may be falsely prolonged by cool ambient temperature ($<20^{\circ}\text{C}$ [$<68^{\circ}\text{F}$]). It is not affected by fever.
- Children with a deficit $>15\%$ will show signs of cardiovascular instability such as severe tachycardia and hypotension.
- Physical findings may be more significant for a given degree of dehydration in children with hyponatremia, leading to overestimation of the deficit. Conversely, the clinical picture is reported to be somewhat moderated in hypernatremia.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Diagnosis of dehydration is best made on clinical grounds. The following laboratory tests are sometimes helpful adjuncts.
- Serum sodium
 - Classifies type of dehydration
 - Hyponatremia and hypernatremia are uncommon in dehydration due to gastroenteritis ($<5\%$ of cases).
 - Measure sodium levels in cases of clinically severe disease or if risk factors are present (e.g., infant <2 months of age, history of excessive free water intake, children with significant neurologic impairment limiting their ability to regulate their own intake).
- Rapid glucose test or serum glucose: to detect hypoglycemia due to prolonged fasting

- Urine specific gravity: This is elevated early in dehydration but may not become elevated at all in young infants or in children with sickle cell disease.
- Serum bicarbonate: This is frequently low with diarrheal illness, even in the absence of dehydration. Useful to detect significant acidosis when dehydration is clinically severe
- Blood urea nitrogen (BUN): may rise late in dehydration in children

TREATMENT

ADDITIONAL TREATMENT

General Measures

Oral rehydration therapy (ORT):

- Most children can be managed successfully with ORT, either at home or in a health care setting.
- Use rehydration solution containing 2.0–2.5% glucose and 75 mmol/L Na (e.g., WHO solution) or 45–50 mmol/L Na (e.g., Pedialyte [Ross Laboratories, Columbus, OH], Infalyte [Mead Johnson, Evansville, IN]).
- Replace entire deficit in 4–6 hours: For mild dehydration, 50 mL/kg; for moderate to severe dehydration, 80–100 mL/kg. Include ongoing losses, ~5 mL/kg for each diarrheal stool.
- Begin with slow administration, with strict limits when vomiting is present: 5 mL q1–2 min. For infants, use a syringe or spoon rather than a bottle. After 30–60 minutes, if the oral liquids have been tolerated, increase the volume and rate.
- Have the child's caregiver participate in giving the fluids and provide education with regard to fluid replacement and signs of dehydration.
- Monitor weight, intake and output, and clinical signs. Failure of ORT includes intractable vomiting, clinical deterioration, or lack of improvement after 4 hours.

IV Fluids

- IV fluids are required when ORT fails or is contraindicated, such as in severe dehydration or shock, poor gag or suck, depressed mental

status, severe hypernatremia ($\text{Na} > 160 \text{ mmol/L}$), severe hyponatremia ($\text{Na} < 125 \text{ mmol/L}$), and suspected surgical abdomen.

- Administer IV bolus of normal saline or Ringer lactate, 20 mL/kg, over 10–30 minutes. Repeat as needed to restore cardiovascular stability. Avoid dextrose-containing solutions for boluses except to correct documented hypoglycemia.
- Calculate maintenance fluid requirements: 100 mL/kg/day for the first 10 kg, plus 50 mL/kg/day for the next 10 kg, plus 20 mL/kg/day over 20 kg.
- Calculate fluid deficit based on clinical estimate or known weight loss. For isotonic or hypotonic dehydration, give 1/3–1/2 normal saline with 5% dextrose at a rate adequate to provide maintenance and replace deficit over 24 hours. For hypertonic dehydration, replace deficit over 48 hours using 1/5–1/4 normal saline with 5% dextrose.
- Monitor weight, intake and output, and clinical signs. With hypernatremia, measure serum sodium q4–6h; do not exceed rate of fall of 1 mmol/L/h.
- For mild to moderate isonatremic dehydration, rapid replacement of deficit over 2–6 hours may be possible. Give normal saline at a rate to replace the estimated deficit at a rate of 25–50 mL/kg/h.

Alternative routes of fluid administration

- Enteral fluids may be given via nasogastric (NG) tube when oral fluids are refused.
- Recent studies suggest subcutaneous administration of fluids, facilitated by use of recombinant human hyaluronidase, may be an alternative to the IV route.

MEDICATION

First Line

Most children with dehydration do not require specific medication therapy. For children with significant vomiting, several studies indicate that ondansetron 0.15 mg/kg PO decreases vomiting and facilitates oral rehydration.

INPATIENT CONSIDERATIONS

Admission Criteria

- Failure of oral or IV rehydration within 4 hours
- Severe hypernatremia or hyponatremia
- Substantial ongoing losses indicating a high likelihood of recurrence of dehydration

Discharge Criteria

After initiating ORT, children who are tolerating oral fluids at an acceptable rate to replace their deficit over 4–6 hours may be discharged with a willing and reliable caregiver and complete the ORT at home.

ONGOING CARE

PROGNOSIS

Excellent with appropriate rehydration therapy

COMPLICATIONS

- Severe dehydration may lead to hypovolemic shock and acute renal failure.
- Hyponatremia is associated with hypotonia, hypothermia, and seizures.
- Overly rapid correction of chronic (>36–48 hours) severe hypernatremia or hyponatremia can produce cerebral edema.

PATIENT MONITORING

- After rehydration, children with ongoing losses, as in gastroenteritis, should receive a maintenance solution in addition to regular feedings to maintain a positive fluid balance.
- Recommend 5–10 mL/kg for each diarrheal stool.
- Avoid clear liquids with excessive glucose, such as fruit juices, punches, and soft drinks, as these can promote osmotic fluid losses in the stool.
- In infants <6 months old, do not give large amounts of plain water, which can lead to hyponatremia.

22Q11.2 DELETION SYNDROME (DIGEORGE SYNDROME, VELOCARDIOFACIAL SYNDROME)

Anne S. Bassett • Donna M. McDonald-McGinn

BASICS

DESCRIPTION

22q11.2 deletion syndrome, formerly known as DiGeorge or velocardiofacial syndrome, is a multisystem disorder with variable severity and number of associated features classically including developmental delay, learning difficulties, congenital cardiac anomalies, palatal abnormalities, especially velopharyngeal insufficiency, hypocalcemia, and subtle facial dysmorphism.

- Rarely ($\leq 1\%$), neonates have a severe T-cell immunodeficiency.
- Learning disabilities are usually borderline; rarely severe
- Treatable psychiatric illness is common.

EPIDEMIOLOGY

Prevalence is estimated at up to 1 in 2,000 live births.

RISK FACTORS

Genetics

- Associated hemizygous microdeletion of 22q11.2
- Up to 10% of newly diagnosed cases are inherited.
- 50% recurrence risk at each pregnancy for affected individuals

PATHOPHYSIOLOGY

A developmental defect of the 3rd and 4th pharyngeal arches may be part of the mechanism.

DIAGNOSIS

HISTORY

- The syndrome is underrecognized at all ages; thus, an index of suspicion is needed for any child with multisystem features.
- Neonatal and late-onset hypocalcemia may be present secondary to hypoparathyroidism in up to 60% of cases.
- Congenital anomalies of any organ system, classically cardiac defects, particularly interrupted aortic arch type B, septal defects, tetralogy of Fallot \pm pulmonary atresia, truncus arteriosus, and vascular ring
- Failure to thrive/dysphagia/gastroesophageal reflux disease (GERD), occasional growth hormone deficiency
- Recurrent infections/autoimmune disease
- Developmental delays, especially speech
- Seizures
- Anxiety, OCD and attention-deficit disorder, schizophrenia

PHYSICAL EXAM

Subtle facial dysmorphism (e.g., malar flatness, hooded eyelids, auricular anomalies, small mouth, micrognathia; tubular nose, bulbous nasal tip with hypoplastic alae nasi), not as recognizable in non-Caucasians

- Cognitive/behavioral disorders
- Hypernasal speech
- Heart murmur
- Hypothyroidism; hyperthyroidism
- Renal/urogenital abnormalities
- Scoliosis; other skeletal abnormalities, for example, polydactyly and butterfly vertebrae
- Recurrent otitis media; hearing deficits
- Thrombocytopenia; splenomegaly
- Juvenile rheumatoid arthritis
- Enamel hypoplasia; chronic caries

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Genome-wide microarray, MLPA, or fluorescence in situ hybridization (FISH) using specific probe (may miss smaller deletions)
 - Most common microdeletion in humans
 - Parents also require testing for the deletion.

- CBC with differential
- Calcium and parathyroid hormone (PTH)
- TSH
- Newborns
 - Flow cytometry
- Age 9–12 months (before live vaccines)
 - Flow cytometry
 - Immunoglobulins
 - T-cell function

Imaging

- Echocardiogram
- Renal ultrasound
- Cervical spine radiographs
- Other, as indicated by history and signs

Other

- Audiology assessment
- Ophthalmology assesment

TREATMENT

ADDITIONAL TREATMENT

General Measures

- Cardiac monitoring for aortic root dilation
- Vitamin D supplements (those with hypocalcemia will likely need 1,25-D supplementation and calcium supplements)
- Standard treatments are generally effective for each associated feature.
- Depending on the features, the child manifests, issues may need consultation and/or follow-up:
 - Neurology
 - Cardiology to define aortic arch anatomy (side and branching pattern)
 - Palate team, otolaryngology
 - Gastroenterology/feeding team
 - Endocrinology

- Infant stimulation; educational consultant
- Speech and cognitive intervention for speech and language delays
- Child psychiatry
- Dentistry
- Immunology to monitor T-cell disorder, recurrent infections, allergy, autoimmune disease
- Severe immunodeficiency may require matched sibling bone marrow transplant or thymic transplant.
- Special consideration with surgery/obstetrics/acute injury
 - Risk of hypocalcemia with biologic stress
- Special consideration for infants:
 - Initially withhold live vaccines.
 - Cytomegalovirus-negative irradiated blood products
 - Influenza vaccinations
 - Respiratory syncytial virus prophylaxis.
 - Avoid live viral vaccines in cases of severe T-cell dysfunction. These patients may need immunoglobulin replacement therapy to protect from infections.
 - Most patients with CD4+ cell counts >500 cells/mm³ can be safely and effectively vaccinated with live viral vaccines.
 - Consider varicella immune globulin in a patient with either unknown humoral immunity status or definitive humoral abnormalities and a history of exposure. IV acyclovir may be necessary if varicella develops and patient has severe T-cell defect.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Cardiac monitoring for aortic root dilation
- Monitor growth and development.
- Monitor hearing.
- Monitor for emerging endocrine, psychiatric, autoimmune, skeletal, and other disorders.
- Genetic and reproductive counseling for adolescents and at transition to

adult care

PROGNOSIS

- Most patients survive childhood. Exceptions include those with severe congenital cardiac anomalies or severe immunodeficiency.
- Associated conditions that arise through development and into adulthood include an increased risk for treatable psychiatric illness (e.g., about 1 in 4 develop schizophrenia), autoimmune phenomena, and neurologic sequelae.
- Functioning in adults is correlated most highly with the degree of intellectual deficit and to a lesser degree with severe psychiatric illness. Mortality in adults is elevated compared to unaffected siblings.

COMPLICATIONS

- In the newborn period, patients may present with hypocalcemic tetany/seizures, manifestation of cardiac abnormality, nasal regurgitation, GERD, dysphagia, and recurrent infections.
- Later on, patients present more commonly with speech, neurologic, developmental, and/or behavioral issues.
- Patients are at increased risk for developing multiple later onset conditions, including autoimmune disease, obesity, and psychiatric illness.

CODES

ICD10

- Q93.81 Velo-cardio-facial syndrome
- D82.1 Di George's syndrome

FAQ

- Q: Can patients have severe intellectual impairments?
- A: Most patients with 22q11.2 deletion syndrome have IQs in the borderline range, about 30% fall in the mild intellectual deficit range; a minority are in the average range, and a small minority fall in the moderate to severe intellectual deficit range. Many children have a >10 point split between their verbal and performance IQ; and thus, the full-scale IQ may not reflect the true functional potential; cognitive remediation should be tailored to the individual's relative strengths and weaknesses.

DENTAL CARIES

Ray J. Jurado

BASICS

DESCRIPTION

Dental caries is the process of tooth structure demineralization, ultimately leading to cavitation (cavities). Bacterial metabolism of carbohydrates produces acid, leading to tooth demineralization over time. The presence of 1 or more decayed, missing, or filled primary tooth surfaces in children younger than 6 years old constitutes “early childhood caries” (ECC).

EPIDEMIOLOGY

- 28% of 2–5-year-olds suffer from ECC, which is most prevalent in disadvantaged populations, with those younger than 3 years old largely untreated.
- ECC may lead to increased emergency room visits and admissions, delayed growth and development, and diminished ability to learn.

RISK FACTORS

Dental caries is multifactorial:

- Factors increasing duration of sugar on teeth: frequent consumption of sugars (including prolonged bottlefeeding), sugary beverages, sticky sugars, medications sweetened with sucrose, inconsistent brushing/flossing after meals, pouching of food, tightly spaced teeth that are difficult to clean
- Factors leading to dry mouth (less saliva, less acid buffering): mouth breathing, albuterol inhalers, psychiatric medications
- Factors leading to weaker tooth enamel: lack of systemic or topical fluoride, developmental enamel defects
- Epidemiologic factors (e.g., low socioeconomic status, previous caries experience)

PATHOPHYSIOLOGY

Dental caries develops when oral bacteria, primarily mutans streptococci

(MS), ferment carbohydrates into organic acids, over time demineralizing tooth enamel. Continuous demineralization of tooth enamel leads to enamel cavitation.

ALERT

MS has been shown to be vertically transmitted from caregiver to child, leading to the concept of ECC as an infectious disease.

DIAGNOSIS

HISTORY

- Reactive tooth pain to cold or hot foods, sweets, or biting. Spontaneous pain may be a sign of advanced caries and infection.
- Frequent carbohydrate challenge (bottle, juice, snacks, sweets, meds, etc.)
- Inconsistent brushing and flossing after meals

ALERT

Spontaneous or nocturnal pain (waking up at night) may be a sign of advanced caries and dental infection. See chapter on “[Dental Infections](#).”

PHYSICAL EXAM

- Tooth discoloration: chalky white (initial caries demineralization), yellow, or brown (advanced cavitation)
- Locations on teeth: in-between (interproximal) front incisors, biting surfaces (occlusal) of molars, at gum line (cervical)
- Soft tissue swelling (advanced caries with infection)
- Dental instrument exploration necessary to help confirm diagnosis
- To document and communicate the location of the lesion, a Universal Numbering System is used to identify the specific tooth/teeth involved (Appendix; Figure 2). Each tooth has a unique letter or number.
- Primary teeth are identified by uppercase letters (A–T).
- Permanent teeth are identified by numbers (1–32).

DIAGNOSTIC TESTS & INTERPRETATION

Lab

None

Imaging

Intraoral radiographs (bitewing and periapical views) help to identify radiolucent/carious tooth structure.

Other

Tooth percussion testing and hot and cold testing (inconsistent diagnostic potential) help to identify extent of caries and/or infection.

Diagnostic Procedures/Other

None

DIFFERENTIAL DIAGNOSIS

Developmental tooth hard tissue defects such as

- Hypoplastic or hypomineralized enamel
- Dental fluorosis

TREATMENT

MEDICATION

Acetaminophen or ibuprofen for symptomatic pain management. See antibiotic therapy in the chapter “[Dental Infections](#).”

ADDITIONAL TREATMENT

- Timely restorative care (fillings, crowns) by a pediatric dentist
- Supplemental topical fluoride (high concentration, prescription only, dentifrice, mouthwash, gel, varnish) with the goal of temporarily arresting caries
- Tooth extraction or root canal of infected teeth

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Dental caries essentially results from sugar in addition to time. Prevention of dental caries should focus on minimizing frequency of sugary beverages/ snacks and brushing (with fluoridated toothpaste) and flossing after as many meals/medication administrations as

possible.

- Children should have their first dental visit 6 months after the eruption of their first tooth, or around 1 year of age. This first visit is to assess for dental caries risk factors and give appropriate anticipatory guidance to the parent with the goal of preventing ECC.
- Dental caries can advance quickly, therefore periodic preventive visits (at least every 6 months) are recommended throughout childhood.

PROGNOSIS

- Timely caries risk assessment as well as restoration of tooth structure and function will minimize the child's caries experience and its consequences.
- Initial signs of caries (chalky white demineralization) may be remineralized with excellent oral hygiene and fluoride supplementation. Untreated advanced dental caries leads to irreversible pulpitis, dental infection, and tooth extraction.

CODES

ICD10

- K02.9 Dental caries, unspecified
- K04.0 Pulpitis
- K04.7 Periapical abscess without sinus

FAQ

- Q: When should I refer my patient for his/her first dental visit?
- A: Children should have their first dental visit 6 months after the eruption of their first tooth, or around 1 year of age. This first visit is to assess for dental caries risk factors and give appropriate anticipatory guidance to the parent, with the goal of preventing ECC.
- Q: Why do baby teeth need to be treated if they are just going to fall out?
- A: Dental pain can affect a child's daily activities, leading to delayed growth and development and diminished ability to learn. Premature primary tooth loss due to infection and extraction can lead to eruption and crowding issues in the permanent dentition.

DENTAL HEALTH AND PREVENTION

Johnny I. Kuttab

BASICS

DESCRIPTION

- Dental health and prevention is the practice of maintaining proper oral health to prevent the initiation or progression of oral disease. It is composed of effective oral hygiene, appropriate dietary practices, fluoride exposure, and the establishment of a dental home.
- Dental caries is a disease that generally is preventable. Early risk assessment allows for identification of parent–infant groups who are at risk for early childhood caries (ECC) and would benefit from early preventive intervention. The ultimate goal of early assessment is the timely delivery of educational information to populations at high risk for developing caries in order to prevent the need for later surgical intervention.

EPIDEMIOLOGY

- 42% of children 2–11 years old have had dental caries in their primary teeth.
- 23% of children 2–11 years old have untreated dental caries.
- Children 2–11 years old have an average of 1.6 decayed primary teeth and 3.6 decayed primary surfaces.
- 21% of children 6–11 years old have had dental caries in their permanent teeth.
- Tooth decay is five times more common than asthma and seven times more common than hay fever.
- More than 51 million school hours are lost due to dental-related illness each year.

RISK FACTORS

- Poor oral hygiene
- Poor dietary practices
 - Frequent nighttime bottlefeeding with milk or juice

- Breastfeeding >7 times daily after 12 months of age
- Ad libitum breastfeeding after introduction of other dietary carbohydrates
- A diet high in natural or added sugars
- Frequent sugar-containing snacking between meals
- Delayed establishment of dental home
- Previous caries
- Lack of exposure to fluoride
- Low socioeconomic status
- Immigrant status
- Poor salivary flow
- Special health care needs or chronic conditions

GENERAL PREVENTION

Establishment of a dental home no later than the child's 1st birthday allows the dental practitioner to educate and promote the use of caries-preventing strategies such as dietary recommendations and appropriate oral hygiene.

- The American Academy of Pediatrics (AAP) recommends children 1–6 years of age consume no more than 4–6 oz of fruit juice per day from a cup (i.e., not a bottle or covered cup) and as part of a meal or snack.
- Dietary guidelines include the following:
 - Eating a variety of nutrient-dense foods and beverages
 - Balancing foods eaten with physical activity to maintain a healthy body mass index
 - Maintaining a caloric intake adequate to support normal growth and development
 - Choosing a diet with plenty of vegetables, fruits, and whole grains and low in fat
 - Using sugars and salt (sodium) in moderation

ALERT

- 54% of U.S. preschool children were given some form of over-the-counter medications, most commonly as analgesics, antipyretics, and cough and cold medications. Numerous oral liquid medications contain a high sugar content to increase palatability and acceptance by

children. Frequent ingestion of sugar-sweetened medications has demonstrated a higher incidence of caries in chronically ill children.

- To motivate children to consume vitamins, numerous companies have made “gummy” vitamin supplements. Cases of vitamin A toxicity have been reported as a result of excessive consumption. The AAP recommends that the optimal way to obtain adequate amounts of vitamins is to consume a healthy and well-balanced diet.
- Oral hygiene measures should be implemented no later than the time of eruption of the first primary tooth.
 - Brushing the infant’s teeth after eruption with a toothbrush will help reduce bacterial concentrations. Brushing should be performed for children by a parent twice daily.
 - Flossing should be initiated when adjacent tooth surfaces touch. Parents and caregivers should help or watch over their kids’ tooth brushing abilities until they’re at least 8 years old.
- Optimal exposure to fluoride is an important preventive measure for children. The use of fluoride for the prevention and control of caries is documented to be both safe and effective.
 - When determining the risk–benefit of fluoride, the key issue is mild fluorosis versus preventing devastating dental disease. In children considered at moderate or high caries risk younger than the age of 2 years, a “smear” of fluoridated toothpaste should be used. In all children ages 2–5 years, a “pea-size” amount should be used.
 - Professionally applied topical fluoride, such as fluoride varnish, should be considered for children at risk for caries. Systemically administered fluoride should be considered for all children at caries risk who drink fluoride-deficient water (<0.6 ppm) after determining all other dietary sources of fluoride exposure.

ALERT

Dental caries is a common chronic infectious and transmissible disease resulting from primarily mutans streptococci (MS) that metabolize sugars to produce acid which, over time, demineralizes and cavitates tooth structure (enamel). MS colonization of an infant may occur from the time of birth by “vertical transmission” from mother to infant. The higher the

levels of maternal salivary MS, the greater the risk of the infant being colonized, the greater risk for caries. Along with salivary levels of MS, mother's oral hygiene, periodontal disease, snack frequency, and socioeconomic status also are associated with infant colonization. The initial acquisition of MS occurs at the median age of 26 months during the "window of infectivity." Mothers are recommended to minimize or eliminate saliva-sharing habits such as sharing spoons.

PATHOPHYSIOLOGY

The oral cavity contains a diverse microbiota that is essential for maintaining normal physiology in the oral cavity. Oral bacteria metabolize sugar and produce lactic acid. Lactic acid is responsible for the demineralization of tooth structure and may lead to cavitation and the advancement of caries through the various dental structures. Furthermore, lactic acid alters the oral environment to a more acidic one and thus disrupts the balance of the oral microbiota, causing the appearance of more pathogenic organisms, thereby enhancing the process.

DIAGNOSIS

HISTORY

- Poor oral hygiene
- Poor dietary practices
 - Frequent nighttime bottlefeeding with milk or juice
 - Breastfeeding >7 times daily after 12 months of age
 - Ad libitum breastfeeding after introduction of other dietary carbohydrates
 - A diet high in natural or added sugars
 - Frequent sugar-containing snacking between meals
- Delayed establishment of dental home
- Previous caries
- Lack of exposure to fluoride
- Low socioeconomic status
- Immigrant status
- Poor salivary flow

- Special health care needs or chronic conditions
- Maternal caries
- Dental pain

PHYSICAL EXAM

- Visible plaque buildup
- “Chalky” teeth
- Cavitated teeth
- Gingivitis
 - Red, swollen gingival
 - Spontaneous bleeding
- Abscessed teeth
- Lymphadenopathy
- Pain

ALERT

- Caries risk assessment is a key element of preventive care. Its goal is to prevent disease by identifying and minimizing causative factors and optimizing protective factors.
- Causative factors include maternal caries, low socioeconomic status, frequent sugar snacking, nighttime bottle use, special health care needs.
- Protective factors include brushing twice daily with fluoride toothpaste, proper diet, and having a regular dental home. However, the best predictor of future caries is previous caries.

DIAGNOSTIC TESTS & INTERPRETATION

- Oral swabbing to assess MS bacterial load
- Plaque index
 - Use of disclosing tablets to highlight plaque and score teeth
- Caries risk assessment

Imaging

- Dental x-rays
 - As needed at discretion of the pediatric dentist

DIFFERENTIAL DIAGNOSIS

- Viral infections such as primary herpetic gingivostomatitis, hand-foot-

and-mouth disease, herpangina

- Gingivitis
- Periodontal disease

TREATMENT

MEDICATION

Treatment of dental caries does not involve medication but rather the restoration of decayed teeth along with the establishment of a dental home. Proper oral hygiene and dietary measures need to be introduced to the patient and the parent.

ADDITIONAL THERAPIES

- Probiotics
 - Probiotics are living microbes that beneficially influence the health of the host when used in adequate numbers. Dental probiotics have been shown to act as antagonists toward pathogenic bacteria by a variety of different mechanism. Restoring the oral health to a more balanced one creates a more suitable environment for the prevention of dental caries and proper oral health.
- Increased fluoride exposure
 - When used appropriately, fluoride is both safe and effective in preventing and controlling dental caries.
 - Topically, low levels of fluoride in plaque and saliva inhibit the demineralization of sound enamel and enhance the remineralization of demineralized enamel.
- Sealant application
 - Sealants reduce the risk of pit and fissure caries in susceptible teeth and are cost-effective when maintained. They are indicated for primary and permanent teeth with pits and fissures that are predisposed to plaque retention. At-risk pits and fissures should be sealed as soon as possible.
- Xylitol chewing gum
 - Xylitol is a five-carbon sugar alcohol derived primarily from forest and agricultural materials. Xylitol reduces plaque formation and

bacterial adherence (i.e., is antimicrobial), inhibits enamel demineralization (i.e., reduces acid production), and has a direct inhibitory effect on MS.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

The most common interval of examination is 6 months; however, some patients may require examination and preventive services at more or less frequent intervals based on historical, clinical, and radiographic findings.

PROGNOSIS

The practice of pediatric dentistry is based on prevention. If a dental home is established early, a pediatric dentist can guide the parent and the child on proper oral hygiene and diet, minimizing the risk for the development of caries.

CODES

ICD10

- K02.9 Dental caries, unspecified
- K05.10 Chronic gingivitis, plaque induced
- K05.6 Periodontal disease, unspecified

FAQ

- Q: It's just a baby tooth. Isn't it going to fall out?
- A: Untreated dental caries in children can lead to pain and infection and affect speech and communication, eating and dietary nutrition, sleeping, learning, playing, and quality of life, even into adulthood.
- Q: My child cannot spit yet and swallows the toothpaste. Can I use a fluoride-free "safe-to-swallow" toothpaste?
- A: Latest research has strongly and unequivocally supported the safety and efficacy of fluoride toothpaste in children. The benefit of fluoride far outweighs any potential risks of toxicity. However, use of fluoride should be based on individual risk factors. In children considered at moderate or high caries risk younger than the age of 2 years, a smear of fluoridated toothpaste should be used. In all children ages 2–5 years, a pea-size amount should be used.

DENTAL INFECTIONS

Johnny I. Kuttub

BASICS

DESCRIPTION

A dental infection is an acute or chronic inflammatory response of the dental pulp (pulpitis) tissue caused by the invasion of bacteria secondary to caries or trauma. Pulpal infection can lead to necrosis of the pulp tissue and cause an abscess (localized collection of pus) to form.

- Reversible pulpitis is a condition when pulpitis can be reversed such as the placement of a filling in a tooth.
- Irreversible pulpitis is a condition that cannot be reversed and rather leads to necrosis of the nerve and eventual abscess deposition.

EPIDEMIOLOGY

- Periapical abscesses account for 47% of all dental-related attendances at pediatric emergency rooms in the United States.

RISK FACTORS

- Poor diet (high in sugar)
- Poor hygiene (visible plaque on teeth)
- Dental caries
- Low socioeconomic status
- Lack of dental home due to access to care

PATHOPHYSIOLOGY

- Most dental infections are a result of the advancement of dental caries from the enamel, into the dentin, and finally, into the pulp tissue of the tooth.
 - Advancement occurs due to the production of acid by a group of bacteria that metabolize sugar from diet.
 - As more acid is created, the pH of the oral cavity is lowered, which further enhances the cycle.
 - Demineralization of the tooth layers occurs. As the caries process

progresses, the bacteria then invade the pulp where an inflammatory response is initiated.

- Necrosis of the pulp tissue occurs and forms an abscess at the apex of the root, resulting in bone destruction.
- Depending on host factors, infection may remain localized and drain through a sinus tract or may spread into the marrow, perforate the cortical plate, and invade surrounding tissues and facial planes.
- Typically, once full necrosis of the nerve has occurred, the pain subsides, and abscess formation is present.
 - This is particularly dangerous because the abscess can remain localized at the apex of the tooth or proceed between muscles, arteries, and veins into fascial spaces and cause significant and potentially life-threatening problems.
 - However, most are self-limiting and establish intraoral localized drainage.

DIAGNOSIS

HISTORY

- Nocturnal pain
 - Waking up due to pain
- Inability to eat due to pain
- Sensitivity to cold
- Fever
- Swelling
- Typically, symptoms of reversible pulpitis include sensitivity to hot/cold/sugary foods or sensitivity to air/brushing. Pain is acute in nature. When the stimulus is removed, the spontaneous pain subsides. When the tooth is restored, the pain disappears.
- Irreversible pulpitis symptoms include a dull achy pain that is constant, whether a stimulus is present or not. Most patients present to the dentist or the emergency room with irreversible pulpitis or abscess/infection.

PHYSICAL EXAM

- Lymphadenopathy
- Extraoral asymmetry due to swelling
- Intraoral swelling
 - Sublingual, submandibular, vestibular, palatal swelling adjacent to tooth
- Sinus tract or fistula adjacent tooth
- Limited oral opening
- Tenderness to palpation
- Low-grade fever
- Dehydration

DIAGNOSTIC TESTS & INTERPRETATION

Imaging

- Periapical or panoramic radiograph
 - Localized bone destruction or widened periodontal ligament (PDL) space
- CT scan in cases of serious extraoral swelling

Diagnostic Procedures/Other

Dentists perform pulp vitality tests to assess the health of the nerve, which can dictate treatment. Depending on the response of the nerve to cold, electricity, or percussion, a proper diagnosis can be reached.

- Percussion test (tapping on tooth elicits pain)
- Vitality test
 - Cold test
 - Electric pulp test (EPT)
- Mobility of tooth

DIFFERENTIAL DIAGNOSIS

- Reversible pulpitis
- Gingival abscess due to foreign body
- Ulceration (herpetic or aphthous)
- Eruption of permanent tooth

TREATMENT

MEDICATION

Antibiotic use should be considered when symptoms include nocturnal pain, fever, lymphadenopathy, and extraoral swelling.

First Line

- Amoxicillin 20–40 mg/kg/day in divided doses
- Augmentin 25–45 mg/kg/day in divided doses
- Tylenol 10–15 mg/kg/dose every 4–6 hours
- Ibuprofen 4–10 mg/kg/dose every 6–8 hours

Second Line

- Clindamycin 8–20 mg/kg/day in divided doses
- Azithromycin 5–12 mg/kg/day in one dose

ADDITIONAL THERAPIES

- Treatment of irreversible pulpitis or dental infection in primary teeth includes extraction of offending primary tooth or pulpectomy (primary tooth root canal). Extraction is preferred, as the goal is to create the most ideal environment for the permanent tooth to continue to develop. It is not uncommon for the permanent tooth to undergo damage in the presence of a long-term chronic infection.
- Treatment of irreversible pulpitis in permanent teeth includes root canal therapy (removal of the nerve and replacing the nerve with a synthetic filling material) followed by crown.

GENERAL MEASURES

- Space maintenance
 - Space maintenance is important to allow proper growth and development of the permanent teeth.
 - The primary tooth is the best space maintainer.
 - Without opposing or adjacent primary teeth, others may drift or tip into the space left by the extracted tooth, causing the development of malocclusions.
 - Spacers are used for space maintenance.

INPATIENT CONSIDERATIONS

Admission Criteria/Initial Stabilization

- Significant extra- or intraoral swelling due to abscess

- Unusual drowsiness, headache, or a stiff neck; weakness or fainting
- Difficulty swallowing or breathing
- Significant eyelid swelling (e.g., eye swollen shut)
- A rising fever, dehydration, and inability to eat
- Although rare, a dental infection or abscess may spread to fascial planes and cause facial cellulitis.
 - An infection in the buccal space can cause extraoral swelling in the infraorbital, zygomatic, and buccal regions. This most often involves maxillary molars.
 - An infection in the submental space can cause extraoral swelling secondary to infection the mandibular incisors.
 - An infection in the submandibular space can cause extraoral swelling unilaterally in the submandibular region secondary to infection in the mandibular molars.
 - The spread of dental infection through the fascial planes can end at the parapharyngeal or retropharyngeal spaces.
- Dental infections can also spread via lymphatics, veins, and arteries. The cavernous sinus is involved in most fatal spread of dental infection due to the lack of retrograde valves in the veins leading into the sinus. The result may be a cavernous sinus thrombosis.

ALERT

An infection in the submental, sublingual, and bilateral submandibular spaces is referred to as Ludwig angina. Infection may spread down the anterior cervical triangle to the clavicles. Speaking, swallowing, and breathing are severely compromised. This is a medical emergency and requires establishment of a safe airway (intubation).

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Referral to pediatric dentist for treatment
 - Extraction, root canal therapy, restorative treatment
- Thorough dental workup for other caries
- Resolution of abscess/swelling

- Management of space issues caused by extraction
- Establish proper dental home with proper dietary and hygiene intervention and guidance.

PROGNOSIS

The prognosis for a dental infection or abscess is good with proper medical and dental treatment.

FAQ

- Q: It's just a baby tooth. Isn't it going to fall out?
- A: Dental pain can affect a child's daily activities, leading to delayed growth and development and diminished ability to learn. Delayed treatment for a dental infection may cause damage to the permanent teeth or may proceed to a facial cellulitis. Premature primary tooth loss due to infection and extraction can lead to eruption and crowding issues in the permanent dentition.
- Q: I had horrible teeth growing up. Is this genetic?
- A: Genetic variation of the host factors may contribute to increased risks for dental caries; however, research suggests that other risk factors contribute greater such as diet and hygiene.
- Q: I see a pimple on my child's gums, but he does not complain of pain and is sleeping fine. Does this require treatment?
- A: All dental infections involving primary or permanent teeth require some form of treatment. If the body's host factors have localized the infection, drainage may occur with the absence of pain; however, the source of the infection remains. This may lead to damage to succedaneous (permanent) teeth or spread of the infection into a cellulitis.
- Q: I started the course of antibiotics and my child is feeling better. Is it necessary to complete the antibiotic?
- A: It is necessary to complete the entire course of the antibiotic unless an allergic reaction is occurring. Resolution of pain or swelling does not ensure the infection has fully responded to the antibiotic. Follow-up studies suggest that antibiotic use should continue at least 5 days beyond the point of improvement of symptoms.

DENTAL TRAUMA

Ray J. Jurado

BASICS

DESCRIPTION

Dental trauma is defined as fractured, displaced, or lost primary or permanent teeth.

EPIDEMIOLOGY

- 30% of children suffer from traumatic dental injuries to the primary dentition, with the highest incidence at 2–3 years of age.
- 22% of children suffer from traumatic dental injuries to the permanent dentition occurring secondary to falls, traffic accidents or bicycles, violence, sports, and physical abuse.
- 70% of cases involve maxillary incisors, with displacement injuries being the most common.

RISK FACTORS

- Sex: In the primary dentition, the prevalence of injuries ranges from 31 to 40% in boys and from 16 to 30% in girls. In the permanent dentition, the prevalence of dental trauma in boys ranges from 12 to 33% as opposed to 4–19% in girls.
- Age: The most common age for trauma in the primary dentition is from 1.5 to 2.5 years of age when the child is learning to walk. In the permanent dentition, the peak age ranges from 8 to 10 years of age.
- Season: Injuries occur more in summer months than in winter, depending on the population and demographics being studied.
- Occlusion: Increased “overjet” (protrusion of upper incisors) and insufficient lip closure are predisposing factors to traumatic injuries.

PATHOPHYSIOLOGY

- Basic tooth structures: enamel (white outer layer), dentin (yellow inner layer), pulp (nerves, blood vessels, connective tissue), cementum (layer covering roots), periodontal ligament (PDL; supports tooth in socket)

- Types of injuries ([Figure 3](#))
 - Infraction: fracture of the enamel without loss of tooth structure. A “crack” in the enamel
 - Uncomplicated crown fracture: fracture with loss of tooth substance confined to enamel or dentin and not involving the pulp
 - Complicated crown fracture: fracture involving enamel and dentin with a pulp exposure
 - Crown/root fracture: fracture involving enamel, dentin, and cementum
 - Root fracture: dentin and cementum fracture involving the pulp
 - Concussion: injury to tooth-supporting structures, no abnormal loosening or displacement
 - Subluxation: injury to tooth-supporting structures with abnormal loosening, no displacement
 - Lateral luxation: lateral displacement of the tooth in its socket with fracture of alveolar bone plate
 - Intrusion: tooth forced into the socket and locked into position in the bone
 - Extrusion: tooth displacement partially out of the socket
 - Avulsion: complete displacement totally out of the socket
 - Alveolar process fracture: fracture of alveolar bone containing tooth

DIAGNOSIS

HISTORY

- Medical history: allergies, bleeding disorders
- Where did the injury occur: possible contamination, tetanus prophylaxis
- How did the injury occur: Mechanism of impact should be consistent with injury.
- When did the injury occur: affects treatment and prognosis (e.g., avulsions)
- Loss of consciousness: may indicate need to assess for other injuries
- Bite discrepancy: may indicate luxation injury or jaw fracture
- Sensitivity to cold or hot: may indicate crown fracture

ALERT

- Missing teeth should be located. If not, consider aspiration, swallowing, or even displacement to a sinus.
- The history of injury should correlate with the trauma to rule out physical abuse.

PHYSICAL EXAM

- Pediatric advanced life support if life-threatening emergency (ABCD, cervical assessment, etc.)
- Clean face and oral cavity with water or saline.
- Extraoral exam: Assess face and lips for soft tissue injuries and palpate mandible and maxilla for possible fractures.
- Intraoral exam: Assess for intraoral soft tissue injuries, tooth fractures, abnormal tooth position, and tooth mobility.

ALERT

To help determine whether the tooth is primary or permanent, classify the dentition according to age: primary dentition (younger than 6 years of age), mixed dentition (6–12 years of age), permanent dentition (12 years of age and older). Upper primary incisors begin to loosen and exfoliate around 6 years of age.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

None

Imaging

- A soft tissue radiograph helps to identify foreign bodies. A dental film is placed in the vestibule between the lips and a radiograph is taken at 25% normal exposure time.
- Intraoral radiographs (periapical and occlusal views) help to identify root fractures and/or extent of displacements.
- Panoramic radiograph helps to identify jaw fractures.
- CT helps to identify tooth fractures in relation to surrounding bone as well as accurately determine alveolar fracture location and morphology.

Other

- Tooth percussion testing helps to identify severity of tooth concussions.
- Hot and cold testing assess tooth vitality.

Diagnostic Procedures/Other

None

DIFFERENTIAL DIAGNOSIS

Soft tissue lesions must correlate with history and mechanism of trauma to rule out physical abuse.

TREATMENT

MEDICATION

- Acetaminophen for pain management
- Consider antibiotic therapy for severe injuries in cases of infection risk (subacute bacterial endocarditis [SBE] risk, immunosuppression, etc.).

ADDITIONAL TREATMENT

General Measures

- Primary dentition
 - Infraction: no treatment necessary
 - Crown fracture: restoration of tooth structure (tooth colored filling); pulp therapy if indicated
 - Root fracture: extraction of crown and root
 - Luxation: soft diet × 1 week if minor; if severe or interfering with bite, extraction is recommended
 - Intrusion: allow to reerupt if not impinging on permanent tooth bud (determined by intraoral radiograph); extract if impinging
 - Extrusion: if minor: allow for spontaneous realignment; if severe: extraction
 - Avulsion: leave out, do not reimplant, to protect permanent tooth bud
 - Alveolar fracture: reposition alveolar segment and tooth-bonded splint
- Permanent dentition

- Infraction: tooth sealant
- Crown fracture: restoration of tooth structure (tooth colored filling); pulp therapy if indicated
- Root fracture: reposition, tooth-bonded splint
- Luxation: reposition, tooth-bonded splint
- Intrusion: immediate repositioning or spontaneous reeruption
- Extrusion: reposition, tooth-bonded splint
- Alveolar fracture: reposition alveolar segment and tooth-bonded splint
- Permanent avulsion
 - Rinse tooth in cold water if dirty and reimplant into socket immediately and stabilize with finger. Refer to dentist immediately for assessment and splint stabilization.
 - If reimplantation is not possible, place tooth in physiologic media—milk, saline, or Hanks balanced storage medium (avoid touching root).
 - Refer to dentist immediately for reimplantation, tooth-bonded splint, and root canal therapy.
 - Treatment options and prognosis depend on stage of tooth development, time out of socket, and storage medium.
- Mandibular fracture
 - Immediate referral to an oral surgeon who will be able to determine management options

ALERT

- Every minute counts! Permanent tooth avulsions require immediate reimplantation. Prognosis worsens the longer the tooth is out of the socket.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- For most dental traumas, the child should be seen by a pediatric dentist as soon as possible for immediate assessment and treatment to optimize prognosis. Regular follow-up is necessary to reassess site of

trauma.

- It is very difficult to prevent the majority of trauma. It is recommended that mouth/tongue piercings be avoided.
- Most sports injuries can be prevented with appropriate use of mouth guards. The American Academy for Sports Dentistry lists 40 sports for which it recommends the use of mouth guards, including acrobatics, baseball, basketball, cycling, discus, shot put, horseback riding, gymnastics, handball, racquetball, squash, judo, karate, rollerblading, rugby, motor cross, parachuting, skiing, soccer, surfing, skateboarding, ice skating, trampoline, tennis, volleyball, wrestling, weight lifting, and water polo.
- The social impact of dental trauma can be emotional (e.g., school, pictures, social) and financial. The total costs for replacing a single knocked-out tooth can be more than 20 times the preventive cost of a professionally, custom-made mouth guard.

PROGNOSIS

- Prognosis depends on severity of trauma. Minor traumas have relatively good outcomes with timely treatment. Severe traumas highly depend on timely, skilled management and the child's healing abilities.
- In the case of any primary tooth trauma, informing parents about possible pulpal complications, appearance of a vestibular sinus tract, or color change of the crown associated with a sinus tract can help assure timely management.
- Primary tooth displacement may also result in complications involving the developing permanent tooth, including enamel hypoplasia, hypocalcification, crown/root dilacerations, or disruptions in eruption patterns or sequence.

- The Dental Trauma Guide. <http://www.dentaltraumaguide.org/>. Accessed November 25, 2014.

CODES

ICD10

- S02.5XXA Fracture of tooth (traumatic), init for clos fx
- S02.5XXB Fracture of tooth (traumatic), init enctr for open fracture
- K08.119 Complete loss of teeth due to trauma, unspecified class

FAQ

- Q: Why not reposition or reimplant primary teeth?
- A: The treatment strategy in primary teeth trauma is dictated by the concern for the safety of the permanent tooth bud. If the displaced primary tooth has invaded the developing permanent tooth bud, extraction is indicated to minimize damage. Reimplantation may encroach on the permanent tooth bud as well.

DEPRESSION

John I. Takayama • Renée Marquardt

BASICS

DESCRIPTION

- General term that includes major depressive disorder (MDD), dysthymic disorder, depression associated with bipolar disorder, and adjustment disorder with depressed mood
- Syndrome of persistent sadness or irritability associated with a variety of symptoms, resulting in functional impairment in the following:
 - Interpersonal (family, friends) relationships
 - Health (somatic complaints, unhealthy habits)
 - Work or school (task completion, grades)
 - Safety (high-risk behaviors including suicide)

EPIDEMIOLOGY

- Point prevalence: 6–11% of adolescents (age 13–18 years), 3–4% in younger children
- Lifetime prevalence: up to 20% will have diagnosable depression by adolescence
- Ratio of females to males: 1:1 in school-aged children, 2–3:1 in adolescents
- Often chronic with high rate of recurrence
- Often unrecognized; up to 80% of affected adolescents do not receive appropriate care.

RISK FACTORS

- Family history of depression, bipolar disorder, suicidal behavior in 1st-degree relative
- Prior depressive episodes
- Personal history of anxiety disorders, ADHD, learning disabilities, and early losses
- Family dysfunction or caregiver–child conflict
- Negative style of interpreting events and coping with stress

- Substance abuse
- Trauma history (e.g., victim of abuse, bullying)
- Chronic illness (including obesity)

COMMONLY ASSOCIATED CONDITIONS

- 40–70% of children and adolescents with depression have comorbid psychiatric disorders:
 - Anxiety disorders
 - Somatization disorders
 - Disruptive behavioral disorders (e.g., ADHD, oppositional defiant and conduct disorders)
 - Eating disorders
 - Substance abuse
 - Physical or sexual abuse

DIAGNOSIS

SCREENING

- U.S. Preventive Services Task Force recommends routine screening of adolescents for depression in clinical settings that can ensure accurate diagnosis and appropriate management and follow-up; and universal surveillance for younger children.
- If screening identifies depression, diagnosis should be established through formal assessment, and risk for suicidal behavior assessed.
- Screening tools include Patient Health Questionnaire for Adolescents (PHQ-A; sensitivity 73%, specificity 94%), Beck Depression Inventory Primary Care (BDI-PC, sensitivity 91%, and specificity 91%), and Strengths and Difficulties Questionnaire (SDQ, sensitivity 33–63%) for identifying depression in adolescents.
- Additional tools: Kutcher Adolescent Depression Scale, Reynolds Adolescent Depression Screen, Mood and Feeling Questionnaire

HISTORY

- Obtain detailed history of child's mood and functioning at home, at school, and with parents, siblings, teachers, and peers.
- Determine onset and duration of depressive symptoms, associated

stressors, and personal impact (distress or impairment).

- Diagnosis of MDD has not changed between DSM-IV-TR (Diagnostic and Statistical Manual of Mental Disorders) and the recently published DSM-5; requires at least 2 weeks of symptoms 1 or 2; and 4 or more of the remaining symptoms:
 1. Depressed or irritable mood: feeling down, sad, or blue most of the time or being “annoyed” or “bothered” by everything and everyone
 2. Diminished interest or pleasure in previously enjoyable activities (events, hobbies, interests)
 3. Change in appetite or weight
 4. Sleep disturbance: not feeling well rested, difficulty in waking up in the morning or in falling asleep at night, waking up in the middle of the night or too early in the morning, daytime napping or sleeping, and nighttime arousal
 5. Psychomotor retardation or agitation: talk or move more slowly than typical, exhibit less speech, and longer response latencies; difficulty sitting still, pacing, hand wringing, tantrums, yelling, shouting, and nonstop talking
 6. Fatigue or loss of energy: feeling chronically tired, exhausted, listless, and without energy or motivation (parents may interpret as laziness)
 7. Feelings of worthlessness or guilt leading to reluctance to do things, excessive self-criticism, difficulty identifying positive self-attributes, “I don’t care” attitude, envy or preoccupation with success of others, marked self-reproach or guilt for events that are not their fault
 8. Impaired concentration or indecisiveness: problems with attention and concentration, slowed thinking and processing of information, indecisiveness and procrastination, helplessness or paralysis in taking action
 9. Running or recurrent thoughts of death or suicide or attempts suicide
- Diagnosis should also include assessment of distress and impairment of functioning.
- Patient should not have manic or hypomanic behavior, and symptoms

should not be attributable to substance use or another medical condition.

- If symptoms do not fulfill criteria of MDD, consider dysthymic disorder or depressive disorder not otherwise specified (DSM IV-TR).
- Dysthymic disorder: symptoms less intense but more persistent; depressed or irritable for at least 1 year with two of the following: appetite disturbance, sleep disturbance, fatigue, low self-esteem, poor concentration, difficulty making decisions, or feelings of hopelessness
- Depressive disorder not otherwise specified: clinically significant depressive symptoms that do not meet criteria for MDD or dysthymic disorder
- In DSM-5, dysthymic disorder and chronic MDD are combined in a new category, persistent depressive disorder.
- Adjustment disorder with depressed mood is diagnosed when depressive symptoms occur only in the context of a specific stressor. Important to assess for the following symptoms:
 - Manic symptoms
 - Ask about episodes of elevated or irritated mood associated with increased energy and activity, decreased need for sleep, grandiose thinking, and impulsive behavior.
 - History of manic symptoms suggests bipolar disorder.
 - Premenstrual timing of symptoms
 - If depressed mood is primarily in the days prior to menses, diagnosis may be premenstrual dysphoric disorder.
 - Psychotic symptoms
 - Ask about auditory or visual hallucination, paranoid ideation, and odd beliefs, which suggest either a more serious depression, or a separate psychotic diagnosis.
 - If family reports patient as withdrawn and less motivated, with no clear evidence for sad or irritable mood, this may also suggest a psychotic disorder.

PHYSICAL EXAM

Weight loss or gain may be associated with depression. Somatic complaints (i.e., headaches, abdominal pain) are common in depression. Physical exam should focus on identifying medical conditions that cause

depressive symptoms (hypothyroidism, neurologic conditions, and underlying chronic illness) and evaluating for signs of comorbid conditions such as eating disorders.

- Vital signs: weight loss or weight gain
- Goiter (hypothyroidism)
- Lymphadenopathy (chronic illness, infection)
- Sexual development (delayed puberty may be related to hypothyroidism, anorexia nervosa)
- Extremities: arthritis (rheumatologic disease)
- Neurologic exam (postconcussive symptoms)
- Skin: pale, cool, dry (hypothyroidism); evidence of self-injurious behavior (i.e., scars from repetitive wrist cutting)
- Mental status exam
 - Appearance, alertness, speech, behavior
 - Awareness of environment (orientation)
 - Assessment of mood and affect
 - Memory, judgment, reasoning
 - Motoric slowing indicates severe depression.
 - Abnormal thought content, such as current suicidal ideation or psychotic thoughts, should prompt immediate referral.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Vitamin B₁₂, free T4, TSH, or other labs based on history and exam to identify contributing or associated medical condition
- Screening for substance abuse as indicated

DIFFERENTIAL DIAGNOSIS

- Medical
 - Mood disorder related to a medical condition
 - Endocrine: hypothyroidism, Addison disease
 - Neurologic: postconcussive syndrome
 - Metabolic: vitamin B₁₂ deficiency
 - Autoimmune: systemic lupus erythematosus
 - Infectious: mononucleosis, HIV/AIDS
- Behavioral

- Substance-induced mood disorder
- Psychiatric
 - Adjustment disorder with depressed mood
 - Bipolar disorder

TREATMENT

- Assessment of severity of depression
 - Determine severity by considering number of symptoms, thought content and process, risk for suicidal behavior, and impact on functioning.
 - Mild depression: 5 or 6 symptoms with mild impairment in functioning
 - Moderate depression: 6–8 symptoms with mild to moderate impairment in functioning
 - Severe depression: all 9 symptoms or 5 or more symptoms and reports specific suicide plan, clear intent, or recent attempt; psychotic symptoms; severe impairment in functioning (i.e., inability to leave home)
- Safety assessment and planning
 - Instruct family to remove lethal means and monitor risk factors for suicidal behavior.
 - Provide patient and family with emergency contacts if risks for suicidal behavior increase.
 - Establish clear follow-up plan.
- Initial management of mild depression
 - Supportive management including education of patient and family about depression and stress reduction, clinical and community support, and management of identified stressors
 - Schedule visits with primary care clinician weekly or biweekly for 6–8 weeks for monitoring.
 - If depression worsens or does not improve in 4–6 weeks, additional intervention is needed.
- Management of moderate or persistent (lasting more than 6–8 weeks) depression

- Education, support, stress reduction
- Psychosocial interventions (counseling, therapy), antidepressant medication, or combination of both
- Among adolescents, psychosocial and medical interventions are equally effective, with slightly increased benefit with combination. Choice of intervention depends on resources, patient/family preference, and individual clinical factors (i.e., age, severity of depression, family history of treatment response).
- Among adolescents, 1st-line antidepressant medication is selective serotonin reuptake inhibitors (SSRIs).
- Among preadolescent children, little evidence for effectiveness of antidepressant medication with elevated risk of serious side effects; refer to child psychiatrist if antidepressants needed
- Antidepressant use in adolescents and young adults are associated with a slight increase in risk of suicidal thoughts and behaviors. These medications, however, have a favorable risk benefit ratio and can be used safely with appropriate patient education and monitoring.
- Omega-3 fatty acids (1,000 mg/day) may be effective in both children and adolescents.
- If patient is referred for therapy, continue frequent monitoring until depression is resolved.
- Several types of therapy can be used for depression. For adolescents, evidence for effectiveness of cognitive behavioral therapy (CBT) and interpersonal psychotherapy (IPT)
- Special diagnostic considerations
 - Premenstrual dysphoric disorder: SSRIs can be used as the 1st-line treatment.
 - Adjustment disorder: When depressed mood is only in context of a specific stressor, psychosocial interventions, rather than medications, are recommended.

ISSUES FOR REFERRAL

Patients with depression can be successfully managed by primary care clinicians. Referral to a mental health provider is recommended for the following:

- Risk for acute suicidal behavior: Refer to emergency services (child crisis).
- History of suicide attempts
- Presence of substance abuse
- Presence of manic or psychotic symptoms
- No improvement after 6–8 weeks of treatment
- Recurrent or chronic depression
- Severe functional impairment
- Psychiatric comorbidities
- Complicated psychosocial factors, such as dysfunctional family dynamics
- After initiating referral to a mental health provider, primary care clinician should continue to follow patient while he or she waits for an appointment and throughout treatment course.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- In the initial phase (6–9 months or longer), the primary care clinician must identify medical conditions associated with depression, provide support and resources, assess patient safety and review safety plan, and monitor response to psychosocial and medical treatments.
- In the continuation phase (6–12 months), patients continue psychosocial or pharmacologic treatments used to achieve remission in the acute phase for at least 6 months, 12 months if difficulties in achieving remission, history of recurrent depression, or presence of ongoing risk factors; patients are typically seen biweekly or monthly by mental health providers depending on clinical status, functioning, support systems, stressors, motivation for treatment, and comorbid psychiatric or medical disorders.
- When asymptomatic for 6–12 months, patients may be recommended for either maintenance phase or discontinuation of treatment.

PROGNOSIS

- Up to 30–40% of patients with MDD can be expected to recover by 6

months and 70–80% by 12 months; 5–10% have protracted episodes lasting longer than 2 years.

- Time to recovery is influenced by age at onset of illness, severity, presence of comorbid disorders, and parental history of depression.
- Shorter duration of symptoms at the time of diagnosis is associated with better outcomes; thus, early identification is recommended.
- Probability of recurrence following recovery of a major depressive episode is approximately 40% by 2 years and 70% by 5 years.

CODES

ICD10

- F32.9 Major depressive disorder, single episode, unspecified
- F33.9 Major depressive disorder, recurrent, unspecified
- F34.1 Dysthymic disorder

FAQ

- Q: What is the PHQ-9?
- A: The PHQ-9 is a self-completed screening survey composed of 9 questions that ask about the frequency of symptoms of depression. If a patient reports 5 or more symptoms more than half the days during the past 2 weeks, the clinician must consider MDD as a diagnosis.
- Q: How should clinicians interpret the “Black Box Warning” about SSRIs?
- In 2004, the Food and Drug Administration issued the Black Box Warning, the most serious type of warning in prescription drug labeling, to inform the public about increased risk of suicidal thoughts or behavior in children and adolescents treated with SSRI. Given evidence for improvement of depression with SSRIs, clinicians should weigh the risks and benefits with the patient and family in deciding treatment; adolescents treated with SSRIs must be closely monitored for any worsening in depression, emergence of suicidal thinking or behavior, or unusual changes in behavior, such as sleeplessness, agitation, or withdrawal from normal social situations.
- Q: What is CBT?
- A: In CBT, the therapist guides and helps a patient to understand and modify dysfunctional thoughts, feelings, and behaviors. If a patient believes that he is worthless, the therapist may encourage him to challenge the negative and irrational belief by understanding patterns in his thinking that relate to such a belief.

DERMATOMYOSITIS/POLYMYOSITIS

Megan L. Curran

BASICS

DESCRIPTION

Juvenile dermatomyositis (JDM) and juvenile polymyositis (JPM) are inflammatory myopathies in which inflammation of capillary endothelium of muscle, skin, and other tissues causes vascular and tissue damage. JDM patients present with characteristic rashes and muscle weakness. JPM patients have inflammatory myopathy but lack skin findings. Both disorders have a wide range of severity and presenting findings.

EPIDEMIOLOGY

- The average age of onset is 7 years, but 25% of cases are diagnosed by 4 years of age.
- Male-to-female ratio in the United States is 1:2.3.
- JDM incidence is 3.2 new cases per 1 million children per year; JPM is extremely rare.

RISK FACTORS

- Underlying genetic susceptibility
- Environmental triggers
 - Ultraviolet light exposure
 - Infectious triggers are inconsistently reported, including group A β -hemolytic streptococci, coxsackievirus B, toxoplasma, enterovirus, and parvovirus.
 - Reports of drug exposure, vaccination, and psychological stress prior to diagnosis, but no causation has been found

Genetics

- Genetic factors, including the following:
 - HLA alleles: B8, DRB1*0301, DQA1*0501, DQA1*0301
 - Cytokine polymorphisms: TNF α -308A promoter, various IL1 genes, interferon regulatory factor 5, and others, all resulting in upregulated inflammation

- Polymorphisms of immunoglobulin constant regions
- Epigenetic factors likely exist: Monozygotic twin studies show low concordance.

PATHOPHYSIOLOGY

- Vasculopathy in patients with underlying inflammatory genetic susceptibility, triggered by environmental factors
- JDM: immune attack on muscle capillary endothelium with infiltration of plasmacytoid dendritic cells causing a type I interferon response and upregulation of myofiber MHC class I expression
 - Immune complex deposition and complement activation drive vasculopathy
 - Upregulation of ICAM-1 and von Willebrand factor antigen indicates endothelial injury.
 - After vasculopathy and MHC class I upregulation, plasmacytoid dendritic and other immune cells infiltrate perivascular and perimysial tissue, resulting in upregulated type I interferon response which perpetuates inflammatory processes including increased production of proinflammatory cytokines
- JPM: CD8 T cell and myeloid dendritic cell-mediated attack on myofibers causing myonecrosis; no increased interferon response
- Myositis-specific and associated autoantibodies directed against vascular and muscle antigens implicated in pathogenesis of JDM and JPM
- Maternal cell chimerism reported in peripheral blood T cells and muscle tissue of JDM patients may be autoreactive toward host cells.

COMMONLY ASSOCIATED CONDITIONS

- Dermatomyositis in children is not associated with presence of malignancy as seen in adults.
- Celiac disease is rarely associated with JDM.

DIAGNOSIS

Bohan and Peter criteria (1975): not validated in children but nonetheless used. Definite JDM requires rash plus three other criteria; probable JDM

requires rash plus two other criteria:

- Characteristic rashes: heliotrope discoloration of eyelids and/or erythematous papules over extensor surfaces of joints (Gottron papules)
- Symmetric proximal muscle weakness
- Elevated serum skeletal muscle enzymes
- Electromyographic (EMG) findings of myopathy and denervation; characteristic MRI findings are often substituted to fulfill EMG criteria in children, although are not specific.
- Muscle biopsy with characteristic abnormalities

HISTORY

- Onset is often insidious but can be rapid.
- Constitutional
 - Fever and adenopathy in some children
 - Anorexia, weight loss
 - Fatigue is a sign of muscle weakness and immune activation.
- Skin: characteristic rashes, ulceration, mouth sores, sun sensitivity, limb edema, calcinosis cutis; Raynaud phenomenon and erythema around fingernails due to vasculopathy
- Weakness (e.g, difficulty rising, climbing stairs, getting out of bed or chair, combing hair)
- Gastrointestinal (GI)
 - Dysphonia, dysphagia, choking, and regurgitation of liquids through nose indicate pharyngeal muscle weakness.
 - Constipation, early satiety from muscle weakness, and gut vasculopathy
 - Abdominal pain and hematochezia from gut vasculopathy
- Musculoskeletal: myalgia, arthralgia, arthritis, joint contractures
- Often strong family history of various autoimmune diseases

PHYSICAL EXAM

- Classic rashes in JDM:
 - Heliotrope rash: violaceous discoloration of upper eyelids; can be accompanied by lid swelling, capillary telangiectasia, discoloration below eyes

- Gottron papules: scaly, erythematous, symmetric, usually hypertrophic but sometimes atrophic papules over extensor surfaces of joints, especially fingers, elbows, knees, and ankles

ALERT

- Findings requiring immediate evaluation: tachycardia, dyspnea, dysphagia, hematochezia, severe abdominal pain, and inability to stand up from the floor or walk
- Other cutaneous findings in JDM:
 - Malar rash
 - V-sign: erythema of upper chest; shawl-sign includes erythema of shoulders
 - Nailfold capillary telangiectasia
 - Overgrown, ragged cuticles
 - Edema of skin overlying inflamed muscles
 - Erythema, dilated vessels, ulcerations of hard palate and buccal mucosa
 - Dermatitis of scalp
 - Ulcerations of skin especially of inner canthi, elbows, or at sites of calcinosis
 - Calcinosis cutis is a late finding:
 - Tumorlike calcium deposits at pressure points: elbows, scapulae, ischia
 - Sheetlike or nodular calcification around joints, axillae
- Musculoskeletal
 - Core weakness: neck, abdominal muscles
 - Proximal weakness: symmetric weakness of shoulder abductors, hip flexors
 - Distal muscle weakness in severe cases
 - Muscle tenderness
 - Waddling (Trendelenburg), wide-based or marching gait due to weak hip flexors
 - Arthritis and joint contractures

ALERT

- Some JDM patients have little to no muscle weakness

(amyopathic/hypomyopathic JDM). Patients seemingly without weakness with facial, hand, and/or other vasculopathic rashes can be misdiagnosed with eczema or psoriasis.

- Rarely, patients may have myositis and vasculopathic skin findings but lack heliotrope changes and Gottron papules.
- GI: diffuse abdominal tenderness, distension, palpable stool
- CV: tachycardia, murmurs, tachypnea
- Physical exam tips
 - Gower sign: inability to rise from floor without using hands
 - Lying supine on flat exam table without a pillow, patients with neck and abdominal weakness will have difficulty lifting head (chin to chest) or shoulders off bed.
 - Objective measure of strength: duration of straight-leg raise (normal = 20 seconds)
 - Use ophthalmoscope or otoscope to examine nailfolds for telangiectasia.
 - Evaluate for dysphonia by asking child to say “Nancy” or “jug”—listen for a nasal quality to voice.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Muscle enzymes: creatine kinase, aldolase, lactate dehydrogenase, aspartate aminotransferase, alanine aminotransferase
 - One or more is elevated in most cases

ALERT

Creatine kinase and/or other muscle enzymes can be normal or low in patients with hypomyopathic JDM or long duration of untreated disease.

- Markers of immune activation
 - ESR and C-reactive protein often normal
 - Inflammatory findings in complete blood count often not present
 - Elevated neopterin: secreted by activated macrophages and dendritic cells
 - Elevated von Willebrand factor antigen: marker of endothelial activation

- Complement generally normal; if low, consider overlap syndrome
- Autoantibodies
 - Antinuclear antibodies with various antigen specificities may be present.
 - ~63% of JDM/JPM patients have a myositis-specific antibody (MSA). Anti-p-155 and MJ antibodies most common; anti-synthetase antibodies (i.e., Jo-1), anti-Mi-2, and anti-signal recognition particle are rare in childhood-onset disease.
 - Myositis-associated antibodies (MAAs) are seen in ~16% of JDM/JPM patients, including anti-Ro, anti-U1RNP, and anti-PM-Scl.
 - MSAs and MAAs should be tested by immunoprecipitation using validated assays.
 - Rheumatoid factor and double-stranded DNA antibodies are usually negative; if positive, consider overlap syndrome.
 - Consider celiac disease testing if with GI symptoms, anemia, and weight loss.
- Occult blood in stool; anemia if blood loss

Imaging

- MRI: Inflamed muscles are identified by signal enhancement on short T1 inversion recovery (STIR) or fat-suppressed T2 sequences; useful to locate site for biopsy
- Video swallow study to identify palatal or proximal esophageal weakness, aspiration
- PFTs to evaluate for respiratory musculature weakness and interstitial lung disease
- EKG and possibly ECHO to evaluate for myocarditis, myocardial dysfunction

Diagnostic Procedures

- Muscle biopsy
- Skin biopsy
- EMG is rarely used in children but can help support diagnosis.

Pathologic Findings

- Skeletal muscle: perifascicular atrophy; variation in fiber size due to

degeneration and regeneration; focal necrosis; lymphocytic and mononuclear infiltrates in the perimysium and perivascular spaces (perifascicular), overexpression of MHC class I

- Skin: epidermal atrophy, dermal and perivascular lymphocytic infiltrates

DIFFERENTIAL DIAGNOSIS

- Infectious/postinfectious: influenza A and B, coxsackievirus B, schistosomiasis, trypanosomiasis; bacterial/pyomyositis if focal
- Trauma (physical, toxic, or drug-induced)
- Myositis with other connective tissue diseases
 - Systemic lupus erythematosus
 - Systemic sclerosis
 - Overlap syndromes including mixed or undifferentiated connective tissue disease
 - Other forms of idiopathic inflammatory myopathy (extremely rare in children): inclusion body myositis, cancer-associated myositis, eosinophilic myositis/fasciitis
- Childhood neuromuscular diseases
 - Muscular dystrophies
 - Congenital myopathies (nemaline rod)
 - Myotonic disorders
 - Metabolic myopathies (glycogen metabolism disorders, mitochondrial myopathies, familial periodic paralysis, lipid myopathies [carnitine deficiencies], myoadenylate deaminase deficiency, myopathy secondary to endocrinopathy)
 - Neurogenic atrophies (spinal muscular atrophy and anterior horn cell dysfunction, peripheral nerve dysfunction, neuromuscular transmission disorders)
- The differential diagnosis for JPM is broader than JDM due to lack of skin findings.

TREATMENT

MEDICATION

- Early aggressive therapy improves overall outcome and reduces frequency of calcinosis.
- Prednisone 1–2 mg/kg/24 h PO (maximum 60 mg) for 1 month, taper over months to years
- IV methylprednisolone 30 mg/kg/24 h (maximum 1,000 mg) for 3 infusions at treatment onset; may also be given weekly
- Methotrexate, usually 15 mg/m² (maximum generally 25 mg) weekly; SC or IV preferred—PO absorption is poor due to gut vasculopathy
- IV gammaglobulin, especially helpful for rash
- Hydroxychloroquine, especially useful for rash
- 2nd-line immunosuppressants: cyclosporine, mycophenolate mofetil
- Biologic agents for refractory disease including rituximab and abatacept under investigation
- Topical calcineurin inhibitors for rash
- Aggressive broad-spectrum photoprotection with physical blockers (i.e., titanium dioxide) and chemical blockers (i.e., avobenzone)
- Calcium and vitamin D supplementation
- Treatment of calcinosis may include sodium thiosulfate, diltiazem, and bisphosphonates.

ISSUES FOR REFERRAL

- Pediatric rheumatologist for diagnosis and management
- Speech therapist for dysphagia
- Gastroenterology, cardiology, or pulmonary referral depending on involved organ system
- Plastic surgery referral may be indicated for excision of severe calcifications, but there is risk of recurrence and infection.

ADDITIONAL THERAPIES

- Physical and occupational therapy
 - Initially to maintain range of movement
 - Strengthening after acute inflammation resolves
 - Depending on disease severity, patients may require extensive, long-term therapy.

INPATIENT CONSIDERATIONS

Respiratory compromise occasionally requires mechanical ventilation.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Serial evaluation of muscle strength and function using validated measures such as the Childhood Myositis Assessment Scale or Manual Muscle Testing
- Muscle enzyme levels to monitor treatment efficacy and flare of inflammation
- Joint range of motion
- Skin exams to check for ulceration, calcinosis
- Steroid-induced myopathy is possible; consider if weakness worsens or does not improve during treatment

PATIENT EDUCATION

- Lifelong sun avoidance and sun protection
- Steroid side effects and warnings about physiologic dependence

PROGNOSIS

- Presence of myositis-specific or associated antibodies can predict disease course.
- Normal to good functional outcome: 65–80%
- Minimal atrophy or joint contractures: 24%
- Calcinosis cutis: 12–40%
- Wheelchair dependent: 5%
- Death: 1–3% (sepsis, GI bleeding or perforation, respiratory failure, myocarditis)

COMPLICATIONS

- Infections, sepsis due to immunosuppression
- Ulcerative rash and scarring
- Calcinosis cutis
- Skin infections at sites of ulceration, calcinosis
- Lipoatrophy, lipodystrophy
- Muscle fibrosis or arthritis causing joint contractures
- Restrictive, interstitial lung disease

- Aspiration pneumonia due to respiratory weakness and swallowing dysfunction
- Myocarditis (rare)
- GI tract vasculitis causing ulcerations, perforation
- Osteoporosis due to inflammation and glucocorticoids

CODES

ICD10

- M33.00 Juvenile dermatopolymyositis, organ involvement unspecified
- M33.02 Juvenile dermatopolymyositis with myopathy

FAQ

- Q: Is it mandatory to perform a muscle biopsy to confirm the diagnosis?
- A: Biopsy is indicated if diagnosis is in any way uncertain. In patients with classic rash, weakness, and elevated muscle enzymes, MRI may suffice. However, biopsy results potentially provide prognostic information.

DEVELOPMENTAL DELAY

Rita Panoscha

BASICS

DESCRIPTION

- Developmental delay is a descriptive term, not a specific diagnosis, comprising many disorders and encompassing a broad category of etiologies.
- The term describes any situation where a child is not meeting age-appropriate milestones as expected in 1 or more streams of development. These streams of development include gross motor, fine motor, receptive and expressive language, adaptive, and social ([Appendix, Table 1](#)).
- The key feature is that the rate of progress has been slow over time in the area(s) of delay.

ALERT

- Children with behavioral problems may also be masking developmental delays.
- Children with delays in 1 stream of development may also have delays in other areas of development. For example, language delay may be an indication of general cognitive delays.
- Hearing impairment may present as a delay in development.

EPIDEMIOLOGY

Found in both sexes and all racial and socioeconomic groups

Prevalence

This is a heterogeneous group of disorders with different prevalence rates.

GENERAL PREVENTION

There is no known prevention of developmental delays, although prevention of some of the underlying causes is possible.

PATHOPHYSIOLOGY

- This is highly variable depending on etiology, which can include

genetic, familial, metabolic, infectious, endocrinologic, traumatic, anatomic brain malformations, environmental toxins, and degenerative disorders as causes. These disorders often result in some neurologic or neuromuscular injury causing the delay. In many cases, the etiology is never determined.

- Prevalence of this group of disorders may vary depending on the inclusiveness of the definition. The milder delays are quite common and can be found in any pediatric practice. Some disorders in this grouping are more prevalent in boys. The long-term outcome depends on the severity and type of delay, with the more involved children usually having lifelong disability.

ETIOLOGY

Specific etiologies are too numerous to list completely, but a partial list of the more common causes includes the following:

- Genetic/familial
 - Fragile X syndrome
 - Trisomy 21 (Down syndrome)
 - Other chromosomal abnormalities
 - Tuberous sclerosis
 - Neurofibromatosis
 - Phenylketonuria
 - Muscular dystrophy
- Nervous system anomalies
 - Hydrocephalus
 - Lissencephaly
 - Spina bifida
 - Seizures
- Infections
 - Prenatal cytomegalovirus
 - Rubella
 - Toxoplasmosis
 - HIV
 - Postnatal bacterial meningitis
 - Neonatal herpes simplex
- Endocrinologic

- Congenital hypothyroidism
- Environment
 - Heavy metal poisoning such as lead
 - In utero drug or alcohol exposure
- Trauma/injury
 - Closed head trauma
 - Asphyxia
 - Stroke
 - Perinatal cerebral hemorrhages

COMMONLY ASSOCIATED CONDITIONS

- There are numerous associated findings including seizures, sensory impairments, feeding disorders, psychiatric disorders (especially depression), and behavioral disorders.
- Having a child with significant developmental delays can also add stress to the family in terms of time, finances, and emotions.

DIAGNOSIS

HISTORY

A complete and detailed history is needed, including the following:

- Pregnancy history
 - Maternal age and parity
 - Maternal complications (including infections and exposures)
 - Medications/drugs used
 - Tobacco or alcohol used, along with quantities
 - Fetal activity
- Birth history
 - Gestational age
 - Birth weight
 - Route of delivery
 - Maternal or fetal complications/distress
 - Apgar scores
- General health
 - Significant illnesses, hospitalizations, or surgeries

- Accidents or injuries
- Hearing and vision status
- Medications used
- Known exposures to toxins
- Any new or unusual symptoms
- Developmental history
 - Current developmental achievement in each stream of development
 - Age when developmental milestones were achieved
 - Any loss of skills
 - Where parents think their child is functioning developmentally
- Educational history
 - Type of schooling and services received, if any
 - Any previous educational/developmental testing
- Behavioral history
 - Any perseverative or stereotypical behaviors
 - Interaction skills
 - Attention and activity level
- Family history
 - Anyone with developmental delays, neurologic disorders, syndromes, consanguinity

PHYSICAL EXAM

- A complete physical exam including growth parameters is needed looking for etiology.
- Key features to include:
 - Observation of interactions and behavior: any atypical behaviors and general impression
 - Head circumference: Assess for macrocephaly or microcephaly.
 - Skin: Examine for neurocutaneous lesions
 - Major or minor dysmorphic features: any indication of a syndrome or anatomic malformation
 - Neurologic examination: Assess for cranial nerve deficits, neuromuscular status, reflexes, balance and coordination, and any soft signs.
 - Developmental testing: Although considerable information will already be available on history and observation, a more formal

developmental screening or testing should be done. Possible office tests include the Ages & Stages Questionnaires, the Parents' Evaluation of Developmental Status, or the Cognitive Adaptive Test/Clinical Linguistic and Auditory Milestone Scale (CAT/CLAMS). Referral to a specialist or a multidisciplinary team for more detailed testing is indicated when delay is suspected.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

Initial lab tests

- There is no specific laboratory test battery for general developmental delays. The testing needs to be tailored to the individual situation based on the history and physical exam. A high index of suspicion should be maintained for any associated findings and delays in the other streams of development.
- Some of the more common studies ordered for developmental delay workup:
 - Genetic testing: warranted for any dysmorphic features, a family history of delays, or genetic disorder. A karyotype and fragile X DNA testing should be considered, particularly for significant cognitive delays. The comparative genomic hybridization (CGH) microarray is now increasingly recommended as a 1st-line test for developmental delays.
 - Metabolic tests: Tests such as quantitative plasma amino acids, quantitative urine organic acids, lactate, pyruvate, or ammonia should be considered if there is any loss of skills or indication of a metabolic disorder.
 - Thyroid function tests: Most infants will have had screening for hypothyroidism shortly after birth. This should be rechecked if symptoms indicate.

Imaging

Head MRI: Consider a head MRI for head abnormalities, significant neurologic findings, loss of skills, or for workup of a specific disorder such as trauma or leukodystrophy.

Diagnostic Procedures/Other

- Audiologic: Hearing should be checked in any child with speech and language and/or cognitive delays.
- EEG: An EEG should be considered if there is any concern about seizures.
- Subspecialists: Referral to other medical specialists may also be indicated. These specialists may include developmental pediatrics, neurology, genetics, orthopedics, or ophthalmology.

DIFFERENTIAL DIAGNOSIS

- The differential can be extensive and may become more evident with further workup.
- Broad diagnoses include the following:
 - Intellectual disability
 - Developmental language disorder
 - Autism
 - Learning disability
 - Cerebral palsy
 - Attention-deficit/hyperactivity disorder
 - Significant visual or hearing impairment
 - Degenerative disorders

TREATMENT

ADDITIONAL TREATMENT

General Measures

- Therapy should include appropriately treating any medical conditions and associated findings, for example, anticonvulsants for seizures or hearing aids when appropriate for hearing impairment. In addition, traditional therapy has included early intervention or special education services specifically addressing the areas of delay.
- Therapy could include physical therapists, occupational therapists, speech/language therapists, special educators, psychologists, and audiologists, depending on the needs of the child.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- General pediatric care for well-child visits and to monitor any underlying medical conditions is indicated.
- These children need ongoing monitoring of their therapy and educational programs to ensure that it is still meeting their individual needs as these needs change over time.
- The families will also need ongoing counseling and support in dealing with a child having special needs.

PROGNOSIS

Variable depending on the type and severity of delay and the etiology

CODES

ICD10

- F89 Unspecified disorder of psychological development
- F82 Specific developmental disorder of motor function
- F80.9 Developmental disorder of speech and language, unspecified

FAQ

- Q: When do you test a child for delays?
- A: A child can have developmental assessments at any age, including infancy. Making a specific diagnosis, for example, for level of intellectual disability, may need to wait until the child is older.
- Q: When can a child start receiving services?
- A: Children who qualify can receive therapy services starting at birth and in some cases extending up to age 21 years.
- Q: The parents are raising a concern about delays, but the general impression in the office is that the child is doing okay. What should be done next?
- A: Parents or grandparents may be the first to express concerns, especially in a child with milder delays. A more detailed developmental history and more formal developmental screening or testing may be indicated as an initial step.

DEVELOPMENTAL DYSPLASIA OF THE HIP

Syed I. Ahmed • John E. Tis

BASICS

DESCRIPTION

Developmental dysplasia of the hip (DDH) is a range of hip pathology including dysplasia (shallow acetabulum), subluxation (partial femoral head–acetabulum contact), and dislocation (no hip joint contact).

Abnormalities can be present at birth or develop over time. A teratologic dislocation is a different condition that occurs during fetal development usually from genetic/syndromic causes. Discussion of teratologic dislocation is beyond the scope of this chapter.

EPIDEMIOLOGY

- Female-to-male ratio is 4:1.
- Incidence varies from 1.5 to 25 in 1,000 births.
- Dislocation incidence is about 1 in 1,000 births.

RISK FACTORS

- Compressive factors:
 - Breech position (newborn DDH risk: male 2.6%, female 12%)
 - Oligohydramnios
 - Firstborn child
 - High birth weight
- Demographic factors:
 - Female gender (newborn DDH risk 1.9%)
 - Family history (newborn DDH risk: male 0.9%, female 4.4%)
 - Ethnicity: Native American, Laplander

Genetics

No defined mode of inheritance; family history, gender, and ethnicity association

GENERAL PREVENTION

Although DDH cannot be prevented, treatment is directed at preventing

early arthritis. Screening programs have reduced the newborn dislocation rate to 1 in 5,000 children by the age of 18 months.

PATHOPHYSIOLOGY

The acetabular depth (growth) is determined by healthy cartilage and development around a concentrically reduced/stable femoral head. Cartilage damage occurs from continued instability. Untreated subluxation/dislocation can result in an everted labrum, hypertrophic cartilage/labrum complex (neolimbus), and false acetabulum (pseudoacetabulum). In early adulthood, this can lead to abnormal wear of the joint, limb length differences, and arthritic pain. Compensatory problems may include spinal malalignment (scoliosis/lordosis) and gait abnormalities.

ETIOLOGY

- Mechanical factors: attributed to a smaller in utero environment from oligohydramnios, breech position, increased birth weight, or an unstretched uterus (first pregnancy)
- Female predominance: attributed to estrogen-induced ligamentous laxity
- Left side predominance: attributed to fetal positioning of left hip adduction against the mother's lumbosacral spine
- Native American predominance: attributed to the hip extension/adduction position of swaddling

COMMONLY ASSOCIATED CONDITIONS

- Neurologic conditions (e.g., myelomeningocele)
- Connective tissue disorders (e.g., Ehlers-Danlos)
- Syndromic conditions (e.g., Larsen syndrome)
- Myopathic disorders (e.g., arthrogryposis)

DIAGNOSIS

HISTORY

Gestational age, gender, birth weight/order, delivery method/position (breech), and family history (DDH or associated conditions [see earlier])

should be asked.

PHYSICAL EXAM

- Ensure that the child is relaxed and calm.
- Screening should be done at all well-child visits until normal ambulatory development.
- Newborn exam
 - Hard signs (<3 months old):
 - Ortolani test: The contralateral hip is flexed, abducted, and held with one hand to stabilize the pelvis. The other hip is held with the thumb in the groin crease and the index/middle finger over the trochanter. With the hip flexed (90 degrees), the trochanter is lifted (anteriorly) as the hip is abducted. An unstable hip will “clunk” as it reduces.
 - Barlow test: similar hand position as the Ortolani test. The hip is flexed (90 degrees), and as the hip is adducted, a posterior stress is applied. An unstable hip will palpably slip out of socket.
 - Galeazzi sign: With bilateral hip and knee flexion, an asymmetry in knee height occurs from apparent femoral shortening on the dislocated side.
 - Soft signs:
 - “Packaging” abnormalities: torticollis, limb deformity (metatarsus adductus), joint contractures, or dislocation of other joints
 - Asymmetric skinfolds (low sensitivity)
 - Sacral dimple
- Ambulatory child exam:
 - Stiffness: limited abduction (normally abduction >75 degrees, adduction >30 degrees)
 - Limb length difference: unilateral toe walking, abnormal Galeazzi sign, scoliosis
 - Gait: lurching to one side (Trendelenburg gait)
 - Bilateral dislocation: may have waddling gait and hyperlordosis. Galeazzi sign will be normal. May be difficult to recognize.

ALERT

- Early diagnosis and referral are paramount.
- Main instability indicators are the Barlow and Ortolani exams. Perform these gently.
- Soft tissue clicks superficial in sound and most asymmetric thigh folds are normal.
- An unreducible hip may have a falsely normal Ortolani/Barlow exam but will be Galeazzi positive.
- Exam and risk factors guide future screening and referral.

DIAGNOSTIC TESTS & INTERPRETATION

Imaging

- If the clinical exam findings are clearly abnormal, then refer the patient. No further imaging is needed for referral.
- Imaging is used to clarify an equivocal examination and to monitor treatment progress.
- Ultrasound
 - Optimal age: 3 weeks to 5 months
 - Static examination: Superior acetabular coverage (α -angle) and femoral head position (β -angle) can be assessed.
 - Dynamic examination: assesses stability
- Plain radiographs (AP pelvis \pm frog lateral)
 - Optimal age: after 3–6 months
- CT scan/MRI
 - Used to assess concentric hip reduction after orthopedic surgical intervention

DIFFERENTIAL DIAGNOSIS

- Septic hip
- Congenital coxa vara
- Proximal femoral focal deficiency

TREATMENT

ADDITIONAL TREATMENT

General Measures

- Treatment principle: Acetabular remodeling potential rarely exists after

4 years of age. When remodeling potential exists, treatment goals are to redirect the femoral head into the acetabulum with minimal force while avoiding complications of avascular necrosis and cartilage damage.

ISSUES FOR REFERRAL

Primary care providers (PCPs) algorithm of care:

- Initial (newborn) exam
 - Abnormal (hard exam findings): orthopedic referral
 - Inconclusive (soft exam findings only): send for ultrasound after 2–3 weeks of age. If abnormal, refer.
 - Normal exam
 - If no risk factors: Reexamine at every well-child visit until normal ambulatory development.
 - If lower risk (female, male with family history):
 - Reexamine during well-child visits until normal ambulatory development.
 - If intermediate risk (female with family history, male born breech):
 - Consider future imaging: ultrasound (~4–6 weeks), radiographs (~6, 12 months)
 - If intermediate risk (female with breech position)
 - Obtain future imaging: ultrasound (~4–6 weeks) and radiographs (~6, 12 months)
- Follow-up (postnewborn) exam: if abnormalities exist after the initial newborn period, then referral with ultrasound (if <5 months of age) or radiographs (if >4–6 months of age)

ADDITIONAL THERAPIES

Pavlik Harness

- Indications: if earlier criteria is met for referral but referral is not possible and child is <6 months of age or the PCP is trained in Pavlik harness use
- NOTE: Abduction brace (more rigid) can be used if treatment extends past 6 months of age when the child becomes more ambulatory.
- For a hip that reduces:

- Place harness full time with joint reduced (may confirm with ultrasound).
- Reexamine hips and readjust harness every 3 weeks.
- Repeat ultrasound ~6–12 weeks.
- Once hip exam is normal, continue full-time Pavlik use for additional 6–12 weeks.
- Radiograph at 6, 12 months
- For hip dislocation (nonteratologic):
 - Follow the earlier protocol except
 - ▢ Initial ultrasound and radiographs for documentation of dislocation
 - ▢ Clinically reassess every 7–10 days until hip reduces.
 - ▢ If hip reduces, document with ultrasound.
 - ▢ Radiographs at 3 months
 - ▢ Refer patient and abandon harness treatment if not reduced by 3 weeks.
- Pavlik harness application:
 - Chest strap: nipple level, snug
 - Shoulder strap: should cross posteriorly, snug
 - Stirrup: should start distal to the popliteal fossa
 - Anterior strap: midaxillary line strap adjusted so hip is flexed at 90–100 degrees
 - Posterior strap: attaches over the scapula, adjusted so hips do not adduct (do not force abduction)

ALERT

- Pavlik harness use is safe when properly placed.
- Never force the hip into position.
- Improper use can lead to cartilage damage, femoral nerve palsy, and avascular necrosis.

SURGERY/OTHER PROCEDURES

- Closed reduction: used when Pavlik harness treatment fails. Spica cast is applied for 2–6 months.
- Open reduction: used when closed reduction fails usually due to soft tissue interposition and/or muscle contracture. Common after 6 months

of age. Adductor tenotomy is usually done. Spica cast is applied after.

- Osteotomy: After about age 2 years, excessive force is needed for a closed/open reduction. Femoral osteotomy reduces this risk along with an open reduction. For residual dysplasia, acetabular osteotomies are performed.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

See “[Issues for Referral](#)” section.

PROGNOSIS

- 95% successful resolution of an abnormal Ortolani exam when Pavlik harness treatment is initiated in a newborn
- 85% success when the same treatment is started after 1 month of age

COMPLICATIONS

- Pavlik harness
 - Tight shoulder strap: brachial plexopathy
 - Hip hyperflexion: femoral nerve palsy, inferior dislocation
 - Forced abduction: femoral head damage resulting in growth arrest or avascular necrosis. Growth arrest can cause trochanteric overgrowth and abductor lurch.
 - Poor hygiene: skin breakdown (groin crease and popliteal fossa)
- Failure or lack of treatment: residual dysplasia/instability/growth arrest resulting in limb length difference, scoliosis/lordosis, arthritis, gait disturbance, and toe walking

CODES

ICD10

Q65.89 Other specified congenital deformities of hip

FAQ

- Q: Are screening protocols unified?
- A: Screening and treatment protocols can vary, but the principles are the same. The earlier screening protocol is adopted from the American Academy of Pediatrics Clinical Practice Guideline and Johns Hopkins Pediatric Orthopaedics.
- Q: Why are ultrasound and radiographs used at different age ranges?

- A: After about 3 months of age, radiographs become easier to assess, as radiographs require ossification and ultrasound waves cannot penetrate ossified bone. The hip is not fully ossified at birth, rendering early radiographic examination difficult.
- Q: Why are the Barlow/Ortolani exams used before 3 months of age but not as useful later?
- A: These exams become less useful as the hip naturally stiffens after 3 months, as stiffness results in asymmetric motion but not instability.

DIABETES INSIPIDUS

Todd D. Nebesio • Sheela N. Magge

BASICS

DESCRIPTION

Polyuria and polydipsia caused by the inability to produce or respond to antidiuretic hormone; also called arginine vasopressin

EPIDEMIOLOGY

Incidence

Because most cases are secondary to another disease, the incidence depends on the primary cause.

RISK FACTORS

Genetics

- Rare genetic causes of central diabetes insipidus (DI) are usually autosomal dominant mutations (neuronal degeneration) and rarely recessive (biologically inactive hormone).
- Nephrogenic DI is usually familial (autosomal recessive or dominant and X-linked).

PATHOPHYSIOLOGY

- Antidiuretic hormone stimulates the formation of cyclic adenosine monophosphate (cAMP) in the renal collecting ducts, thereby increasing water permeability and increasing reabsorption of free water.
- Lack of antidiuretic hormone effect results in urinary loss of free water.
- Patients with an intact thirst mechanism drink copiously (polydipsia) to compensate for free water loss.
- If the thirst mechanism is not present or if access to free water is limited (e.g., infants, developmentally delayed child, or vomiting), severe dehydration can occur.

ETIOLOGY

- Insufficient antidiuretic hormone secretion

- Traumatic or postsurgical
- Nonaccidental injury
- Related to tumor invasion of posterior pituitary
- Extension from anterior pituitary/suprasellar: optic glioma, rarely adenomas
- Hypothalamic: germinoma, craniopharyngioma, meningioma
- Lymphoma
- Granulomas: histiocytosis, sarcoidosis
- Metastatic carcinoma
- Post–severe ischemic or hypoxic injury to the brain
- Familial (autosomal dominant)
- Congenital malformation of CNS
- Infection: viral encephalitis, meningitis, tuberculosis
- Increased metabolic clearance of antidiuretic hormone (gestational DI)
- Drug or toxin related: snake venom, tetrodotoxin
- Autoimmune disorders: hypophysitis (inflammation of the pituitary gland)
- Psychogenic: excessive water drinking
- Idiopathic: must observe for many years to exclude slow-growing tumors
- Unresponsive to antidiuretic hormone
 - Familial or nephrogenic (X-linked dominant and autosomal recessive forms)
 - Tumor related
 - Urinary tract obstruction, especially in utero
 - Renal medullary cystic disease
 - Electrolyte disturbances: hypokalemia, hypercalcemia (hypercalciuria)
 - Drugs: usually reversible (diuretics, diphenylhydantoin, reserpine, cisplatin, rifampin, lithium [may become permanent], demeclocycline, ethanol, chlorpromazine, volatile anesthetics, foscarnet, amphotericin B)
 - Loss of the medullary concentrating gradient due to excessive free water intake relative to solute intake

ALERT

Pitfalls

- Management of patients without an intact thirst mechanism and of newborns is difficult.
- Patients with psychogenic polydipsia may fail a water deprivation test because prolonged excessive water intake can wash out the renal medullary gradient required for concentrating the urine.
- Surreptitious water intake during water deprivation test
- Idiopathic, acquired DI can be caused by slowly growing brain tumors not visible on the initial magnetic resonance image.

DIAGNOSIS

HISTORY

- Abnormal growth can be a sign of DI.
- Waking up during the night to drink or void:
 - True DI is associated with polyuria throughout the day and night. Enuresis may be the first sign in a child who previously acquired bladder control. Patients, including infants, prefer ice-cold water to other liquids.
- Number of hours the patient goes without drinking:
 - Patients with complete DI do not voluntarily stop drinking for >1–2 hours unless the thirst mechanism is also abnormal.
 - Patients with DI have such overwhelming thirst that they will drink anything, including bath and toilet water.
- Volume of urine output in a day (not just frequency of urination):
 - The daily volume of urine can be as high as 4–10 L. Younger or dehydrated children with DI tend to make less urine daily than older or hydrated children with DI.
- Familial history of DI:
 - Nephrogenic DI will typically affect maternal uncles during infancy, and mothers may have a mild form.
- Frequent episodes of dehydration requiring medical attention:
 - Families may disregard the polydipsia as normal behavior. Repeated episodes of severe dehydration can damage the brain.

- Treatment of adrenal insufficiency in a patient with panhypopituitarism can unmask DI (i.e., one needs cortisol in order to excrete free water).

PHYSICAL EXAM

- Signs of dehydration:
 - DI is typically associated with dry, pale skin and mucous membranes. Because this is hyperosmolar dehydration, the patient may not look as severely dehydrated as she or he is.
- Complete neurologic exam:
 - Check for impaired visual fields, which can be the first sign of brain tumor.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Morning urinary osmolality with simultaneous serum sodium and serum osmolality
 - If urine osmolality is at least 2 times higher than serum osmolality, patient does not have complete DI but may still have partial DI.
- Water deprivation test
 - Although definitive, it requires admission to the hospital for controlled testing under the close supervision of a pediatric endocrinologist. Patient fails test if urinary osmolality cannot concentrate more than twice serum osmolality at the same time that serum osmolality exceeds 305 mOsm/kg; serum osmolality exceeds 305 mOsm/kg at any time; or patient loses >5% of body weight and becomes symptomatic from hypovolemia.
 - Once patient fails the water deprivation test, a dose of aqueous vasopressin should be given followed by close monitoring of urinary osmolality to document responsiveness to antidiuretic hormone.
 - Never attempt a water deprivation trial at home. Tell parents to allow free access to water at home in any suspected cases.
- Urinary specific gravity (nonspecific)
 - Insufficient by itself and nondiagnostic during a water deprivation test
- 24-hour urine collection (home testing)

- To obtain accurate urinary volume while patient has free access to water

Imaging

MRI of the brain with and without contrast, with special cuts of the pituitary and hypothalamus: to confirm the bright spot normally seen in the posterior pituitary and to search for tumors. Its absence is not pathognomonic of central DI.

ALERT

Do not restrict water intake unless the patient is in the hospital under close surveillance.

DIFFERENTIAL DIAGNOSIS

- Psychogenic polydipsia
- Abnormal thirst mechanism (dipsogenic DI)
- Hypernatremic dehydration
- Diabetes mellitus
- Polyuric renal failure (e.g., renal tubulopathy)
- Hypercalcemia
- Cerebral salt wasting
- Hyperthyroidism
- Hypokalemia

TREATMENT

MEDICATION

- DDAVP: intranasal spray or oral tablets
- Aqueous vasopressin: subcutaneous (SC):
 - Comes as 4 mcg/mL solution and doses range from 0.05 mcg up to 1 mcg SC b.i.d. daily. Titrate dose as you would with DDAVP.
- Duration of action of DDAVP is variable from patient to patient. Titration and frequency of dosing should be made under supervision of a pediatric endocrinologist.
- Control of DI in infants is more difficult. These patients may increase fluid intake because of hunger or increase caloric intake because of

thirst, thereby causing an imbalance between free water intake and output. Infants can be treated with diluted formula—the volume and frequency of feedings will be increased, but intake of free water will better match urine output. DDAVP should not be used in infants. In some cases, low renal solute load formula (e.g., Similac PM 60/40) and/or thiazide diuretics have been used in infancy. Strict record keeping of intake/output and accurate daily weighing are usually necessary for infants or patients without an intact thirst mechanism. All infants with DI must be treated by experienced providers.

- Nephrogenic DI may be treated with diuretics and solute restriction as these patients are resistant to DDAVP.
- Side effects:
 - Facial flushing
 - Increased blood pressure
 - Headache
 - Nasal congestion
 - Hyponatremia: caused by water overdose (intoxication), not by overdose of drug. Taking a higher dose of DDAVP will generally extend the period of antidiuresis but will not cause hyponatremia. Drinking too much water in the setting of antidiuresis causes hyponatremia. Water intoxication most often occurs in antidiuresed patients who also are on intravenous fluids, lack an intact thirst mechanism, or have psychogenic polydipsia.
- Treatment duration is generally lifelong; some tumors regress with radiation, allowing recovery of antidiuretic hormone secretion.
- Possible conflicts with other treatments:
 - Nasal congestion or gastrointestinal illness can affect the absorption of DDAVP administered.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Depends on the patient and underlying disease causing the DI
- When to expect improvement:

- Effects of DDAVP are immediate.
- Most cases of DI are lifelong; one exception is DI that occurs during the 7–10 days immediately after neurosurgery because this postsurgical DI may resolve spontaneously within 1–2 weeks after surgery (part of the triple-phase response).
- Signs to watch for:
 - Lethargy
 - Somnolence
 - Irritability
 - Hyperpyrexia
 - Any sign of dehydration
 - Seizures

DIET

- Patients with an intact thirst mechanism should drink only when thirsty.
- Patients without an intact thirst mechanism should drink only a carefully calculated fluid volume.

PROGNOSIS

- Generally good but depends on the primary cause
- May cause developmental delay if the hypernatremia is prolonged

COMPLICATIONS

- Without treatment and without access to water:
 - Hypernatremia
 - Dehydration
 - Coma
- When overdosed with water:
 - Hyponatremia
 - Seizures
 - Cerebral edema

- N25.1 Nephrogenic diabetes insipidus

FAQ

- Q: In a patient with an intact thirst mechanism and partial DI, is the use of DDAVP necessary?
- A: No, as long as the patient has constant access to free water.
- Q: How does therapy of DI affect daily life? Is it easily integrated into normal activity and eating patterns?
- A: DDAVP is used in a patient with an intact thirst mechanism to facilitate the daily routine as well as to allow patients to sleep without the need to void frequently during the night.
- Q: Is there a longer acting preparation or an implantable pump for dosing?
- A: The longest acting form of antidiuretic hormone is an injected medication and can have effects for 3 days, increasing the risks of hyponatremia. Home use of the nasal spray or tablets, therefore, is easier and safer than the use of injections.
- Q: In cases of central DI, is it necessary to screen for anterior pituitary

hormone deficiencies?

- A: Yes—at diagnosis of DI and during follow-up as other pituitary hormone deficiencies can occur over time.

DIABETES MELLITUS, TYPE I

R. Paul Wadwa

BASICS

DESCRIPTION

Type 1 diabetes is an autoimmune disorder that causes pancreatic B-cell destruction. This destruction leads to insulin deficiency that results in hyperglycemia and disrupts energy storage and metabolism. Severe insulin deficiency can lead to ketosis, acidosis, dehydration, shock, and death.

EPIDEMIOLOGY

- Most common endocrine disorder of childhood
- More common in whites of Northern European descent

Incidence

- Annual U.S. incidence is ~19/100,000 in children 10–19 years old.
- Incidence of type 1 diabetes is rising by 3% per year but faster in young children.

Prevalence

- Prevalence of type 1 diabetes in youth 0–19 years in United States is ~2/1,000.
- Note: At least 2% of diabetes in children may be due to maturity onset diabetes of youth (MODY) or other genetic forms.

RISK FACTORS

Genetics

- Increased susceptibility to type 1 diabetes associated with HLA region of chromosome 6, 5-fold greater risk with MHC antigen types DR3 and DR4
- MODY is a group of autosomal dominant syndromes of partial insulin deficiency due to monogenic defects of pancreatic development or insulin secretion; they comprise a small fraction of childhood diabetes.

PATHOPHYSIOLOGY

- Loss of pancreatic B cells results in insulin deficiency, leading to

hyperglycemia, and predominance of catabolic processes.

- Hyperglycemia causes hyperosmolality, polyuria, and damage to small blood vessels.
- Catabolic processes produce ketosis, weight loss, and metabolic acidosis.

ETIOLOGY

- Type 1 diabetes
 - An environmental trigger (likely viral) induces expression of antigens on B-cell surface.
 - Recruitment of cytotoxic lymphocytes
 - Production of anti-insulin and anti-islet cell antibodies (including GAD65, ICA512, ZnT8)
 - Progressive inflammatory, autoimmune loss of B-cell mass results in insulin deficiency.
 - The autoimmune destruction of B cells is more likely in genetically susceptible persons.

COMMONLY ASSOCIATED CONDITIONS

- Autoimmune thyroid disease
 - Hashimoto (hypothyroidism) more common than Graves (hyperthyroidism)
- Celiac disease
- More rarely other autoimmune diseases, such as alopecia areata, rheumatoid arthritis
- Depression
- After prolonged hyperglycemia: vascular complications:
 - Microvascular
 - Nephropathy
 - Retinopathy
 - Neuropathy
 - (See “[Patient Monitoring](#)” for screening recommendations)
 - Macrovascular
 - Peripheral vascular disease
 - Cardiovascular disease

DIAGNOSIS

HISTORY

- Duration of symptoms prior to diagnosis varies by age: may be days in toddlers, months in adolescents.
- Polyuria, nocturia, and enuresis are related to hyperglycemia >180 mg/dL.
- Polydipsia: due to polyuria, hyperosmolality
- Polyphagia: appetite amplified by loss of calories from glycosuria; this is often absent.
- Weight loss: dehydration, loss of calories
- Malaise, nausea, vomiting, abdominal pain, hyperventilation, lethargy due to ketosis, acidosis, electrolyte depletion, hyperosmolality
- MODY is usually asymptomatic.

PHYSICAL EXAM

- Weight loss common at presentation of type 1 diabetes.
- Candidal vaginitis and balanitis common in young children with type 1 diabetes
- In ketoacidosis: dehydration, hyperventilation

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Diagnosis based on BG level:
 - Fasting BG ≥ 126 mg/dL, random BG ≥ 200 mg/dL, or 2-hour BG ≥ 200 mg/dL on oral glucose tolerance test (OGTT), and exclusion of stress hyperglycemia
 - Asymptomatic hyperglycemia requires repeat confirmation.
- Glycosuria may be intermittent.
- Ketonuria may occur with both types 1 and 2.
- With presence of ketonuria or ketosis, DKA should be ruled out by checking serum bicarbonate.
- HgbA1c reflects BG levels of previous 2–3 months and is nearly always elevated at diagnosis of both types.
- GAD, islet cell, ZnT8, and/or insulin autoantibodies are positive in most persons with type 1 diabetes at onset (85–90%)

- In some patients presenting with hyperglycemia and ketosis, not possible to distinguish type 1 from type 2 until the course over several months has been followed

DIFFERENTIAL DIAGNOSIS

- MODY
- Type 2 diabetes (in obese pubertal youth)
- UTI (polyuria)
- Renal glycosuria
- Stress-related hyperglycemia
- Drug-induced hyperglycemia (steroids)
- Psychogenic polydipsia
- Pneumonia (in DKA)
- Sepsis (in DKA)
- Acute surgical abdomen (in ketoacidosis)

TREATMENT

MEDICATION

(See insulin regimens under “[General Measures](#).”) Insulin is required to treat type 1 diabetes.

- Insulins:
 - Rapid-acting analogs:
 - Aspart (Novolog), lispro (Humalog), glulisine (Apidra)
 - Onset of action 5–15 minutes, peak action 60–90 minutes, and duration 2–5 hours
 - Short-acting
 - Regular insulin—used for IV delivery, can be used for SC injection
 - Onset of action when given SC—30–60 minutes, peak action—2–3 hours, duration—6–9 hours
 - Intermediate-acting
 - NPH (Humulin N, Novolin N)
 - Onset 1–2 hours, peak action 3–8 hours, duration 12–15 hours

- Use is less common when long-acting analogs available.
- Long-acting analogs
 - Detemir (Levemir), glargine (Lantus)
 - Onset—3–4 hour, no significant peak, duration 20–24 hours
 - Other long-acting analogs under investigation but are not FDA-approved in 2014 including insulin degludec, which is approved for use in the European Union

ADDITIONAL TREATMENT

General Measures

- Insulin is given as a fixed or flexible regimen.
- TDD—calculated by adding up all short- and long-acting insulin given over 24 hours—usually ~0.7–1.2 U/kg/24 h; choose higher range for ketoacidosis presentation, obesity, and puberty.
- Doses may decline during “honeymoon period.”
- Fixed insulin regimens require fewer shots but consistent schedule and eating.
- Historically, common fixed regimen is split-mixed: 2/3 of TDD in morning (1/3 as short-acting and 2/3 long-acting), and 1/3 of TDD in evening (with 1/2 as short-acting and 1/2 as long-acting), either at dinner or split between dinner and bedtime.
- Flexible insulin regimens consist of basal insulin plus a short-acting bolus for every carbohydrate meal and for high blood sugar.
- Basal dosing
 - 40–50% of TDD is given as 1 injection of a long-acting insulin such as glargine (Lantus) or detemir (Levemir).
 - Sometimes, these long-acting insulins are split into twice daily doses given ~12 hours apart.
- Boluses of short-acting insulin (lispro or aspart) are given for meals and snacks based on carbohydrate content and BGs.
 - Carbohydrate coverage (grams of carbohydrate covered by 1 unit) can be estimated by dividing the TDD to 500.
 - Hyperglycemia coverage (“corrective dose”) can be estimated by dividing the TDD to 1,800 to find how much 1 unit of insulin may lower blood sugar.
- Another flexible method uses SC insulin infusion by pump that

administers a continuous basal infusion.

- Patient gives manually administered bolus doses of rapid-acting analog insulin at mealtimes and corrective doses.
- Dosing guidelines are similar.

ONGOING CARE

PATIENT MONITORING

- Regular appointments with diabetes specialist every 3 months to assess management:
 - HgbA1c assessment at each visit (with generally recommended goal of <7.5% for children)
 - Is diabetes interfering with emotional health, family relationships, school attendance, athletic activities, or social development?
 - Is family minimizing hospitalization risks from hypoglycemia or DKA with appropriate adjustment of insulin, recognition of lows, glucagon availability, ketone testing, and telephone contact?
 - Is family reducing long-term complication risk by keeping HgbA1c lower and by avoiding or treating other risk factors?
 - Exam: growth, weight, blood pressure, thyromegaly, liver size, pubertal status, injection/infusion sites, feet, skin lesions
- Meet with nutritionist periodically/as needed to reassess meal plan.
- Meet with psychologist or social worker as needed to address psychosocial issues.
- Regular screening for long-term complications:
 - Annual urine for microalbumin after 12 years of age, 3–5 years diabetes duration
 - Periodic lipid profile, thyroid screening (T₄, TSH or TSH and thyroid antibodies), celiac screen
 - Annual eye exam to detect early retinopathy after 10 years of age, 3–5 years diabetes duration

DIET

- Dietary education for type 1 diabetes is directed toward healthy distribution and matching of carbohydrate intake with insulin action:

- Recommended distribution of calories: 55% from carbohydrates (mostly complex); 30% from fats; 15% from protein
- Fixed insulin regimens require snacks spaced between meals and before bedtime.
- Carbohydrate counting is essential for flexible insulin regimens and helpful for maintaining consistency for fixed regimens.
- Reduction of saturated and trans fats, rapidly digested carbohydrates, and salt may be beneficial in both types of diabetes.

PATIENT EDUCATION

- Home BG monitoring at least 6 times per day. Many patients will need to test more frequently: before meals, when feeling hypoglycemic or ill.
- Insulin injection and site rotation
- Oral carbohydrate for mild hypoglycemia; glucagon 0.5–1 mg IM for severe hypoglycemia (lower dose given in children <20 kg)
- Activity:
 - Frequent exercise reduces BG and insulin requirements in both types of diabetes.
 - Exercise may require extra carbohydrate intake or reduced insulin doses to prevent hypoglycemia in type 1 diabetes.
 - Detecting or preventing hypoglycemia during or after physical exercise
- Diet: carbohydrate counting
- Prevention: checking urine for ketones when blood sugar is high or child feels ill; extra insulin for ketones

COMPLICATIONS

- DKA: most common cause of hospitalization and death in type 1 diabetes in childhood. See “[Diabetic Ketoacidosis](#).”

ALERT

DKA should be treated in the emergency department or inpatient setting. The risk for morbidity and mortality due to cerebral edema or other complications of DKA is high.

- Hypoglycemia

- This most common acute complication. Limits achievable glycemic control
- If severe, may cause seizure, unconsciousness
- Long-term harm may be reduced by better glycemic control:
 - Nephropathy: Microalbuminuria and hypertension are 1st manifestations before adulthood.
 - Retinopathy: Blood vessel changes may occur in childhood but not vision loss.
 - Neuropathy: diminished nerve conduction velocity common; paresthesias are earliest symptoms.
 - Vasculopathy: Large vessel disease begins in childhood, but clinical effects occur in adults.
 - Prenatal harm to infants of diabetic mothers: Birth defects occur early, large size late.
 - Growth failure (Mauriac syndrome) and delayed sexual maturation
- Depression, family stress, higher divorce rate

CODES

ICD10

- E10.9 Type 1 diabetes mellitus without complications
- E10.8 Type 1 diabetes mellitus with unspecified complications
- E10.21 Type 1 diabetes mellitus with diabetic nephropathy

FAQ

- Q: What is the risk of diabetes in a sibling or child of a person with type 1 diabetes?
- A: It is 5–10% in 1st-degree relatives (siblings, offspring) and 40–50% in identical twins.
- Q: What are the newest management tools?
- A: Continuous glucose sensors allow patients to avoid symptomatic high and low glucoses by detecting trends, to see the outcome of management decisions, and to reduce the risk of severe nocturnal hypoglycemia. Insulin pumps using data from sensors are in development (“artificial pancreas” systems). A pump with a feature to suspend insulin delivery for low glucose detected by sensor is now available.

DIABETES MELLITUS, TYPE 2

Wendy J. Brickman

BASICS

DESCRIPTION

Hyperglycemia, fitting criteria for diabetes, in a setting of insulin resistance with insufficient insulin secretion for given insulin resistance

EPIDEMIOLOGY

- Increased prevalence over past three decades
- Type 2 diabetes mellitus (T2DM) accounts for 15–86% of newly diagnosed cases of diabetes in youth (10–19 years). Wide variation depending on population affected.
- Incidence (per 100,000 person-years, 0–19 years)
 - Pima Indians = 330
 - African American = 10
 - Non-Hispanic whites = 2.8
- Prevalence (per 100,000 youth 10–19 years)
 - Pima Indians = 5,100
 - African American = 106
 - Hispanic = 46
 - Non-Hispanic whites = 18

RISK FACTORS

- Female gender
- Ethnic minorities
- Adolescence (10–19 years)
- Pubertal
- Offspring of mothers with gestational diabetes
- Family history of type 2 diabetes
- History of the following:
 - Large for gestational age at birth
 - Intrauterine growth retardation
- Impaired fasting glucose

- Fasting glucose 100 mg/dL (5.6 mmol/L)–125 mg/dL (6.9 mmol/L)
- Impaired glucose tolerance
 - Based on 2-hour glucose from oral glucose tolerance test (OGTT; see the following) of 140 mg/dL (7.8 mmol/L)–199 mg/dL (11 mmol/L)

PATHOPHYSIOLOGY

- Characterized by insulin resistance and beta cell dysfunction
- Insulin resistance
 - Major abnormality in youth with T2DM
 - A disorder in which tissues (muscle, hepatic, adipose) have a decreased response to insulin, mediated by abnormal phosphorylation of insulin receptor
- Ideally, a compensatory hyperinsulinemia develops to maintain euglycemia.
- In the presence of beta cell dysfunction, inadequate amounts of insulin are secreted to meet demands from insulin resistance.
- This relative deficiency in beta cell function leads to hyperglycemia and diabetes.

DIAGNOSIS

- T2DM usually presents in setting of the following:
 - Family history of type 2 diabetes
 - Overweight or obesity (BMI \geq 85th percentile for age, gender)
 - Other abnormalities associated with insulin resistance (i.e., acanthosis nigricans)
 - Residual (yet abnormal) beta cell function
 - No diabetes autoimmunity

HISTORY

- Asymptomatic (most common)
- Polyuria
- Polydipsia
- Weight loss
- Blurry vision

- Increase in nocturia
- Improvement in acanthosis nigricans
- Family history of type 2 diabetes
- Maternal gestational diabetes
- Medications associated with hyperglycemia:
 - For example: glucocorticoid, growth hormone, atypical psychotics, tacrolimus

PHYSICAL EXAM

- Overweight (BMI \geq 85th percentile but $<$ 95th percentile) or obesity (BMI \geq 95th percentile)
- Hypertension
- Acanthosis nigricans
- Vaginal candidiasis

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Diagnosis of diabetes mellitus:
 - HgbA1c \geq 6.5%
 - Using NGSP-certified method
 - False negatives when increased blood cell turnover is present
 - Fasting glucose \geq 126 mg/dL (7 mmol/L)
 - 2-hour OGTT glucose \geq 200 mg/dL (11.1 mmol/L)
 - At time 0, give oral glucose 1.75 g/kg (maximum dose 75 g) over 5 minutes.
 - At time 120 minutes, measure glucose.
 - If asymptomatic, do 2nd OGTT on a subsequent day to confirm.
 - Random glucose $>$ 200 mg/dL with symptoms of hyperglycemia
- Distinguish type 1 from type 2 diabetes.
 - C-peptide or insulin in setting of hyperglycemia
 - Normal or elevated in type 2 diabetes
 - Low C-peptide or insulin does not rule out type 2 diabetes.
 - Diabetes autoimmune panel
 - Negative usually in type 2 diabetes
 - Pancreatic autoantibodies; insulin, islet cell, IA-2, GAD, ZnT8
- Evaluate for acute complications of diabetic ketoacidosis (DKA) and/or

hyperglycemic hyperosmolar state (HHS).

- Check urine for ketones.
- If urine ketones present (in setting of hyperglycemia), check for DKA.
 - Venous gas: pH <7.30
 - Metabolic panel: HCO_3^- <15 mEq/L
- If urine ketones negative or low and patient appears ill, check for HHS.
 - Serum glucose: >600 mg/dL (33 mmol/L)
 - Serum osmolality: >330 mOsm/kg
 - Metabolic panel: HCO_3^- >15 mEq/L

DIFFERENTIAL DIAGNOSIS

- Type 1 diabetes
- Atypical diabetes
- Medication-induced diabetes
- Maturity onset diabetes of youth (MODY)
 - Monogenic disorders of glucose regulation
 - Abnormalities of beta cell function common
 - However, youth can be overweight or obese.
 - Genetic testing for MODY is available.
- Renal glycosuria
- Stress-induced hyperglycemia

ALERT

Treat youth with possible type 2 diabetes with insulin, as if they have type 1 diabetes, until clinical course and laboratory findings prove otherwise.

TREATMENT

- Treatment will focus on youth presenting with type 2 diabetes who don't have DKA or HHS.
- Goal of treatment is glucose regulation in order to 1) limit hypoglycemia and hyperglycemia and 2) minimize and delay onset of microvascular and macrovascular disease.

MEDICATION

Insulin

- Initiate treatment with insulin unless clinical picture and laboratory studies support type 2 diabetes and not type 1 diabetes.
- If diagnosis is type 2 diabetes, but initial glucose is >250 mg/dL or HgbA1c $\geq 9\%$, insulin therapy is still recommended.
- Initiate basal-bolus insulin regimen (may need to individualize)
 - Total daily dose 0.5–1.0 unit/kg/day (TDD)
 - 40% in long-acting (detemir, glargine) usually given at bedtime
 - For meals and snacks, calculate number of carbohydrates to be eaten and cover with short-acting insulin (lispro, aspart, glulisine).
 - Calculate carbohydrate coverage: 1 unit of insulin for every X grams of carbohydrates, often start with $X = 500/\text{TDD}$.
 - For hyperglycemia prior to mealtimes, give correction doses of short-acting insulin by using the sensitivity factor.
 - Insulin sensitivity factor: 1 unit of insulin will drop glucose by X, often start with $X = 1800/\text{TDD}$.
 - Correct until goal blood glucose is reached: begin with goal 120–150 mg/dL.
- Insulin regimen outlined above gives increased flexibility and decreased risk of hypoglycemia with at least 4 injections a day.
- When hyperglycemia is improved and diagnostic tests supportive of type 2 diabetes, introduce metformin and attempt insulin wean.
- Insulin regimen needs to be tailored to the patient and family, and often alternative regimens with fewer injections but more rigid eating schedules and higher risk of hypoglycemia are preferred.
 - Two injections per day: premixed insulin
 - 2/3 of TDD with breakfast
 - 1/3 of TDD with dinner
 - Three injections per day: split-mixed
 - 2/3 of TDD with breakfast (2/3 NPH, 1/3 short-acting)
 - 1/9 of TDD with dinner (short-acting)
 - 2/9 of TDD at bedtime (NPH)
- Side effect of all insulin regimens is hypoglycemia, especially with increased activity, decreased oral intake, addition of oral

antihyperglycemic. Adjust dose to prevent.

Metformin

- Only FDA-approved medication for type 2 diabetes in youth
- First line of therapy for youth with type 2 diabetes with random glucose <250 mg/dL and HgbA1c <9%
- Begin at 500 mg once a day. Increase by 500 mg every 1–2 weeks as tolerated to reach goal of 2,000 mg daily.
- Side effects:
 - Short-term: anorexia, flatus, abdominal pain
 - Long-term: lactic acidosis (avoid with renal failure, hypoxia, liver disease) and vitamin B₁₂ deficiency
 - Stop 48 hours prior to elective surgery or contrast study with dye.

ADDITIONAL TREATMENT

Weight management

- Physical activity
 - 60 minutes moderate to vigorous activity a day
 - Can be split throughout the day
 - Start with shorter periods of daily activity and gradually increase to 60-minute goal.
 - Treat orthopedic, respiratory issues.
 - Individualize plan: walking to formal sports.
- Sedentary activity
 - Decrease sedentary activity.
 - Limit screen time (handheld devices, computers, television) to <2 hours a day.
 - Remove televisions/screens from bedrooms.
- Nutrition
 - Healthy eating choices
 - Guidelines from Pediatric Weight Management Evidence-based Nutrition Practice Guidelines, Academy of Nutrition and Dietetics
- Surgical intervention (i.e., gastric bypass)
 - Rarely, as part of weight loss program

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Blood glucose monitoring
 - Insulin Rx: preprandial, bedtime
 - Oral medication: Consider fasting, bedtime.
 - Increase when ill, changing dose, concern for low or high glucose.
 - Decrease when stable, in good control.
- Clinic visit with HgbA1c every 3 months
- Goal HgbA1c <7% (may need to individualize); modify treatment as needed.
- Recent study suggests adolescents fail metformin monotherapy rapidly. May need to add additional therapy to reach goals
- Address postprandial glucose excursions to possibly limit risk of macrovascular disease.
- Suggestions for modifying treatment regimen:
 - Introduce long-acting insulin at night.
 - Introduce short-acting insulin at meals.
 - Introduce additional oral antihyperglycemic (not FDA-approved, many with concerns for longer term complications; i.e., rosiglitazone).
- Prevention of DKA and HHS by increasing adherence to treatment plan
- Monitor for hypoglycemia and modify regimens to decrease episodes.
- Little is known regarding disease course in adolescents with T2DM. The SEARCH and TODAY studies have increased our knowledge of prevalence of abnormalities and raised concern for progression of microvascular and risks for macrovascular disease early in course of T2DM.
- Microvascular disease has been noted at presentation or early in course of T2DM.
- Recommendations based on adults (in addition to improving glucose control)
 - Retinopathy
 - Examination at diagnosis, then annually
 - Tx includes laser photocoagulation

- Microalbuminuria
 - Measure at diagnosis, then annually.
 - Abnormal: random: 30–200 mg/kg
 - Perform timed overnight collection. Need 2/3 abnormal samples: 20–199 mcg/min.
 - Treat with ACE inhibitor until microalbumin excretion is normalized.
- Peripheral neuropathy
 - Examination at diagnosis, then annually
 - Changes in sensation in feet, leg
- Autonomic neuropathy
 - Assess at diagnosis, then annually.
 - May present as tachycardia, orthostasis, gastroparesis
- Cardiovascular disease
 - Optimize therapy for hypertension, dyslipidemia, smoking cessation.

ISSUES FOR REFERRAL

- Other disorders are commonly associated with type 2 diabetes and may contribute to development of complications.
- If present, referral/treatment should occur:
 - Hypertension
 - Dyslipidemia
 - Depression
 - Obstructive sleep apnea

CODES

ICD10

- E11.9 Type 2 diabetes mellitus without complications
- Z83.3 Family history of diabetes mellitus
- E11.51 Type 2 diabetes w diabetic peripheral angiopath w/o gangrene

FAQ

- Q: What are some of the challenges of follow-up care in youth with type 2 diabetes?
- A: Possible challenges include the following:
 - Competing financial/time constraints
 - Adolescent age
 - Lack of symptoms from hyperglycemia and early complications of hyperglycemia
 - Lack of social support networks

- Pervasiveness of type 2 diabetes in families

DIABETIC KETOACIDOSIS

Nicole S. Glaser

BASICS

DESCRIPTION

- Severe metabolic derangement in patients with diabetes mellitus (DM) secondary to insulin deficiency and/or stress hormone excess
- Clinical features include hyperglycemia, ketosis, metabolic acidosis, dehydration, and electrolyte deficits.

EPIDEMIOLOGY

Incidence

- Diabetes ketoacidosis (DKA) occurs more commonly in type 1 DM but can also occur in type 2 DM.
- 20–40% of children with new-onset type 1 DM present in DKA.
- Risk of DKA in established type 1 DM is 1–10% per patient per year (most episodes caused by insulin omission/diabetes mismanagement).
- DKA accounts for majority of diabetes-related deaths in childhood (most secondary to cerebral edema/brain injury).

RISK FACTORS

- For type 1 DM presenting as DKA:
 - Very young children (<5 years)
 - Ethnic minority
 - Inadequate health insurance
 - A missed diagnosis of DM in preceding clinic visits is frequent in DKA patients (~35%).
- For DKA in established diabetes:
 - Adolescence
 - Lack of health insurance
 - Poor glycemic control
 - Ethnic minority
 - Low socioeconomic status (SES).

GENERAL PREVENTION

- Prompt diagnosis of new-onset diabetes (e.g., urinalysis in patients with poor weight gain, polyuria, flu-like symptoms/vomiting)
- Patient/parental education regarding ketone testing (with any symptoms of illness or unexplained high blood glucose level)
- Strict supervision of long-acting (glargine, detemir) insulin injections by parents
- Detection and avoidance of insulin pump interruptions by frequent blood glucose testing and strict protocols for changing infusion sets

PATHOPHYSIOLOGY

- Excess of counterregulatory “stress” hormone concentrations (glucagon, cortisol, and epinephrine) in relation to insulin concentrations occurs, either as a result of insulin absence (new-onset diabetes or insulin omission) or illness (raising stress hormone levels)
- Imbalance between counterregulatory hormones and insulin results in increased glycogenolysis and gluconeogenesis and decreased peripheral glucose uptake (causing hyperglycemia) as well as lipolysis and ketogenesis (causing ketosis).
- Hyperglycemia causes osmotic diuresis resulting in dehydration and electrolyte losses.
- Ketogenesis results in metabolic acidosis, causing vomiting and tachypnea.
- Dehydration causes poor tissue perfusion, raising lactate levels and is contributing to metabolic acidosis.

ETIOLOGY

- Insulin deficiency
 - New diagnosis of diabetes
 - Insulin omission (diabetes mismanagement or insulin pump malfunction)
- Acute illness (leading to rise in counterregulatory hormone levels)

COMMONLY ASSOCIATED CONDITIONS

- Acute illness as a precipitating factor
- Autoimmune disorders (especially hypothyroidism) for persons with type 1 DM

DIAGNOSIS

HISTORY

- Symptoms of new-onset diabetes (polyuria, polydipsia, weight loss)
- Nausea, vomiting, abdominal pain, weakness, lethargy

PHYSICAL EXAM

- Vital signs: tachycardia, tachypnea (deep, “Kussmaul” respirations), occasional hypothermia
- Dehydration: dry mucous membranes, sunken eyes, poor distal perfusion
- Fruity breath odor
- Abdominal tenderness and decreased bowel sounds (intestinal ileus)
- Altered mental status, lethargy, obtundation

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Glucose: >200 mg/dL (usual range 200–1,200 mg/dL)
- Urinalysis: glucosuria and ketonuria
- Electrolytes: total body depletion of sodium, chloride, potassium, phosphate, calcium, magnesium (depletion generally not reflected in serum electrolyte concentrations which may be low, normal, or high at presentation)
- Sodium: initial Na usually normal or low
 - Hyperglycemia depresses serum Na by about 1.6 mEq/L for every 100 mg/dL–elevation in glucose greater than 100 mg/dL.
 - Elevated Na at presentation implies extreme dehydration.
- Potassium: Initial serum levels typically normal or elevated, may fall rapidly with therapy.
- Serum bicarbonate (total CO₂) is low, consistent with metabolic acidosis.
 - Bicarbonate <18 mEq/L suggests pH <7.3.
 - Bicarbonate <10 mEq/L suggests pH <7.1.
- Phosphate: typically normal or slightly elevated at presentation
- Blood pH low (<7.3) due to metabolic acidosis. Low PCO₂ secondary

to respiratory compensation for metabolic acidosis

- CBC: White blood cell counts frequently elevated and may be left shifted (even in the absence of infection). Hematocrit may be elevated due to hemoconcentration.
- Serum ketones (β -hydroxybutyrate) are elevated (typically >5 mmol/L).
- Liver enzymes (ALT, AST) may be mildly elevated.
- Amylase and lipase are often mildly elevated.

DIFFERENTIAL DIAGNOSIS

- Gastroenteritis
- Acute abdomen (pancreatitis, appendicitis, bowel ischemia)
- UTI
- Pneumonia, bronchiolitis
- Stress hyperglycemia (particularly during gastroenteritis in young children—ketosis may also be present due to lack of oral intake and may be difficult to differentiate from DKA)
- Salicylate ingestion
- Rare inborn errors of ketolysis (succinyl-CoA: 3-ketoacid CoA transferase deficiency)

TREATMENT

GENERAL MEASURES

Initial emergency treatment consists of fluid resuscitation to insure hemodynamic stability. Most DKA patients require admission to a pediatric critical care unit or other unit with similar capabilities.

ISSUES FOR REFERRAL

The pediatric endocrinology service should be advised of all DKA admissions. New-onset diabetes patients will require diabetes education. Patients with recurrent DKA may require reeducation or other counseling.

INPATIENT CONSIDERATIONS

IV Fluids

- Initial isotonic IV fluid bolus (0.9% saline) of 10–20 cc/kg—may be

repeated as necessary to restore perfusion and hemodynamic stability.

- IV fluid rate after initial bolus(es)
 - Average fluid deficit is ~7% of body weight.
 - Replace deficit evenly over 24–48 hours.
 - Add maintenance fluids to deficit replacement (minus initial boluses) to calculate total rate.
 - Replacement of ongoing urinary fluid losses is generally unnecessary, but urine output should be monitored.
 - Urine output and specific gravity do not reflect state of hydration.
 - Adjust fluid infusion rate based on fluid intake and output balance, clinical measures of perfusion, and laboratory indicators of hydration.
- Composition of IV fluids:
 - After initial isotonic fluid bolus(es), IV fluids should consist of 0.45–0.9% saline.
 - Potassium replacement is essential and should be added to IV fluids as soon as renal failure or extreme hyperkalemia is ruled out.
 - Typical initial K replacement is 40 mEq/L, using 1/2 KCl and 1/2 K phosphate.
 - Dextrose should be added to IV fluids when serum glucose level is below ~250 mg/dL. The “2 bag method” (see reference) is ideal.
 - Dextrose concentrations in IV fluids should be adjusted to maintain serum glucose in the range of 100–200 mg/dL. Rates of insulin infusion generally should not be decreased until acidosis resolves.

Insulin

- Insulin treatment should begin after initial isotonic fluid bolus(es).
- Insulin should be administered via continuous IV infusion at a rate of 0.1 units/kg/h.
- An initial insulin “bolus” or “loading dose” is not necessary.

Other

Treatment with bicarbonate is generally unnecessary and has been associated with increased risk of cerebral edema.

ONGOING CARE

PATIENT MONITORING

- Recommended monitoring:
 - Frequent (at least hourly) assessment of mental status and perfusion
 - Hourly vital signs
 - Cardiac monitor and pulse oximeter
 - Hourly intake and output
 - Hourly fingerstick or serum glucose
 - Electrolytes and venous blood gas every 2–4 hours
 - Ca, Mg, phosphate every 4–6 hours

PROGNOSIS

Mortality of DKA in children is ~0.2–0.3%, (most frequently caused by cerebral edema/ cerebral injury).

COMPLICATIONS

- Cerebral injury is the most frequent DKA-related cause of death (57–87% of DKA deaths).
 - Patients at highest risk for cerebral injury are those with the most severe dehydration and acidosis (often younger children).
 - The cause of brain injury in DKA is unclear but may be related to reduced cerebral perfusion during untreated DKA, followed by injury related to reperfusion.
 - Commonly occurs 2–12 hours after starting treatment with insulin and saline
 - Symptoms may include mental status changes in association with severe headache, recurrence of vomiting, inappropriate slowing of heart rate or hypertension.
 - Loss of consciousness, seizures, apnea, or signs of increased intracranial pressure may also occur.
 - Treatment of suspected cerebral edema includes mannitol (0.5–1 g/kg by IV infusion over 15 minutes) or hypertonic saline.
 - Cerebral imaging studies should be done to evaluate edema or other signs of cerebral injury, but treatment should not be delayed to obtain imaging studies.
- Cardiovascular collapse from shock is rare and usually due to delayed or inadequate IV fluids.

- Other complications:
 - Hypokalemia is frequent and can be avoided with frequent serum K reassessments and adjustment of potassium content of IV fluids.
 - Hypoglycemia may occur but can be avoided with frequent glucose checks and adjustment of dextrose concentration of IV fluids.
 - Mild hypophosphatemia is common, but severe hypophosphatemia is rare. Severe hypophosphatemia has been associated with rhabdomyolysis and hemolytic anemia.
 - Hyperchloremic acidosis may occur, particularly with higher NaCl concentrations in IV fluids.
 - Other rare complications include the following:
 - Pulmonary edema or acute respiratory distress syndrome (ARDS)
 - Pneumomediastinum from hyperventilation
 - Arrhythmias due to electrolyte disturbances
 - Thrombosis, especially at central line site
 - Disseminated intravascular coagulation (DIC)
 - Rhinocerebral mucormycosis
 - Pancreatitis

- E13.10 Oth diabetes mellitus with ketoacidosis without coma

FAQ

- Q: Is DKA in children with known diabetes usually caused by infection or other illness?
- A: Diabetes mismanagement resulting in inappropriate insulin omission is a far more frequent cause of DKA in children than infection. It is generally unnecessary to evaluate children with DKA for infection unless fever or other symptoms of infection are present.
- Q: Does rapid infusion of intravenous fluids or excessive administration of insulin cause cerebral edema in DKA?
- A: At present, neither the IV fluid administration rate nor the rate of insulin administration has been convincingly shown to increase the risk of DKA-related cerebral edema. Recent data suggest that cerebral edema is more likely related to alterations in cerebral perfusion during DKA, and that rates of fluid and insulin administration (within a reasonable range) do not play a primary role.
- Q: How can DKA episodes in children with diabetes be prevented?
- A: Greater supervision of diabetes care by parents or guardians can decrease the likelihood of insulin omission. Parents should also be instructed to test for ketones at the first sign of any illness or with unexplained high glucose levels and to contact the diabetes care team immediately if ketones are positive.

DIAPER RASH

Jocelyn H. Schiller

BASICS

DESCRIPTION

Diaper dermatitis is a general term used to describe any inflammatory skin rash that develops in the perineal region. Also known as diaper or napkin rash, there are several causes of diaper dermatitis. Most often, diaper rash is caused by an acute irritant contact dermatitis, which is the focus of this chapter.

ALERT

- Severe cases of diaper dermatitis may be complicated by bacterial or fungal infection which may require treatment with topical or systemic antibiotics and/or antifungals.
- If severe cases fail to respond to conventional therapies, consider other diagnoses such as Langerhans cell histiocytosis, acrodermatitis enteropathica, or seborrheic dermatitis.

EPIDEMIOLOGY

Incidence

- The reported incidence varies worldwide due to differences in diaper use, toilet training, hygiene, and child-rearing practices.
- Can develop in the 1st week of life, but unlikely once the child is no longer in diapers

Prevalence

- Estimated prevalence ranges from 7 to 35%.

RISK FACTORS

- Diarrhea increases the risk of irritant diaper rash.
- The presence of oral thrush or recent antibiotic use increases the risk of secondary *Candida albicans* infection.
- Formula-fed infants may have higher risk of diaper dermatitis due to higher stool pH.

GENERAL PREVENTION

- Frequent diaper changes and proper skin care help prevent diaper rash.
- Diapers should be changed as often as every 2 hours or sooner if diaper is wet and/or soiled.
- Super absorbent diapers (disposable diapers containing gelling materials) keep moisture away from skin and may prevent diaper dermatitis compared to cloth diapers.
- Some experts recommend soft cloths and water for cleansing due to preservatives in baby wipes. As manufacturers have decreased the number of additives, contact dermatitis due to wipes has become less common.
- Petrolatum and/or zinc oxide provide effective barriers against potential perineal skin irritants and moisture. Several authors advise caregivers to refrain from rubbing barrier products off completely during diaper changes to prevent further skin damage.

ETIOLOGY

The pathophysiology is multifactorial, including moisture, friction, warmth, urine and feces.

- Friction: Rubbing of wet diapers against exposed skin can result in chafing, maceration, and irritation.
- Moisture trapped against skin causes increased permeability and susceptibility to damage from friction.
- Irritation: Urine raises the pH which activates fecal enzymes resulting in skin damage.
- As the skin barrier breaks down, microbes are more likely to cause a secondary infection.
 - Common causes of secondary infections include *C. albicans*, group A β -hemolytic *Streptococcus*, and *Staphylococcus aureus*.

DIAGNOSIS

HISTORY

- Associated symptoms: Acute or chronic diarrhea suggests a primary irritant dermatitis.

- The presence of oral thrush or recent antibiotic use increases the risk of secondary *C. albicans* infection. Presence of the rash for >3 days also increases likelihood of candidal infection.
- Treatment with topical corticosteroid, antifungal, or antibacterial products can change the appearance of the rash.
- Chemicals, dyes, and fragrances in lotions, wipes, diapers, and detergents can cause irritant or allergic contact dermatitis.
- Infrequent or poor hygiene can result in diaper rash, whereas excessive bathing may result in increased friction on the skin and worsening of a preexisting rash.
- Moderate to severe rashes and rashes infected with group A β -hemolytic *Streptococcus* or *Staphylococcus aureus* cause discomfort for the child.

PHYSICAL EXAM

- Ranges from asymptomatic, generalized erythema to skin breakdown leading to an open wound
- Irritant and allergic dermatitis occurs on skin surfaces in direct contact with the diaper, urine, and feces. Skin folds are typically spared.
 - Affected intertriginous areas suggest seborrheic dermatitis, candidal infection, or group A β -hemolytic *Streptococcus* infection.
 - Perianal rashes suggest group A β -hemolytic *Streptococcus* (more common) or *S. aureus* (less common) infection.
- The morphology of the dermatitis is important:
 - Well-demarcated, shiny, erosive, erythematous perianal patches suggest group A β -hemolytic *Streptococcus*.
 - Scattered inflammatory papules or pustules suggest *S. aureus*.
 - Erythematous patches with peripheral erythematous papules (satellite lesions) suggest candidal infection.
 - Greasy erythema and scaling suggests seborrheic dermatitis.
- A complete physical exam may reveal other features of the underlying diagnosis:
 - Scalp seborrhea (cradle cap) suggests seborrheic dermatitis.
 - Thrush (oral candidiasis) raises the possibility of a candidal infection.
 - Hepatosplenomegaly suggests Langerhans cell histiocytosis.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Rarely helpful
- Candidal infections can be verified by a potassium hydroxide preparation or fungal culture of skin scraping if diagnosis is unclear.
- Group A β -hemolytic Streptococcus and *S. aureus* infection can be confirmed by swabbing affected area for bacterial culture.

Pathologic Findings

- Skin biopsy is rarely required unless the rash is atypical and unresponsive to therapy.
- Helpful in diagnosing psoriasis, Langerhans cell histiocytosis, or granuloma gluteale infantum

DIFFERENTIAL DIAGNOSIS

- Candidal dermatitis: Irritant dermatitis may become secondarily infected with *C. albicans*, which results in beefy red plaques with satellite lesions and superficial pustules. Common during or after antibiotic use.
- Allergic contact dermatitis: can result from allergens in the diaper, wipes, or topical creams including dyes, detergents, fragrances, or elastic
- Impetigo: due to group A β -hemolytic Streptococcus (common) or *S. aureus* (less common): 1–2 mm pustules and honey-colored, crusted erosions. Bullous impetigo appears as large, fluid-filled bullae.
- Perianal group A β -hemolytic Streptococcus presents as bright red, sharply demarcated perianal rash with pain or pruritus. May also have streptococcal pharyngitis.
- Seborrheic dermatitis: associated with scalp, face, and skinfold involvement. In the diaper region, it is characterized by well-circumscribed erythematous papules and plaques.
- Atopic dermatitis: usually spares the diaper region due to the moist environment. If affected, characterized by increased skin lines and excoriations due to scratching.
- Psoriasis: may involve the diaper area either exclusively or may occur in the setting of more diffuse presentation, including other

intertriginous areas and the face and scalp. Presents with sharply demarcated erythematous and silvery scaly papules and plaques.

- Scabies: Pruritic, erythematous papules and nodules may involve the genitalia, abdomen, web spaces of extremities, and axilla; often there is a history of multiple affected family members and more widespread involvement.
- Herpes simplex virus may manifest as grouped vesicular, papular, or pustular lesions. May be transmitted through sexual contact or herpetic whitlow.
- Child abuse: An unusual history or morphology suggests the possibility of abuse, especially if the lesions appear geometric or resemble scalds, burns, or bruises or if sexually transmitted disease diagnosed.
- Langerhans cell histiocytosis: usually presents with multiple reddish-brown crusted papules and/or vesicles and petechiae in conjunction with hepatosplenomegaly and anemia
- Acrodermatitis enteropathica, which is caused by impaired zinc metabolism (either inherited or acquired), leads to an erosive acrodermatitis involving the face in a perioral and periocular distribution, the diaper area, and the hands and feet.
- Jacquet erosive diaper dermatitis is rare and likely represents severe irritant diaper dermatitis. Characterized by well-demarcated papules, nodules, and punched out ulcerations.
- Granuloma gluteale infantum is a rare, benign inflammatory dermatosis associated with use of high-potency topical corticosteroids. Characterized by reddish-purple nodules.

TREATMENT

ADDITIONAL TREATMENT

General Measures

- Similar to primary prevention, frequent diaper changes and proper skin care are the primary treatments for diaper dermatitis.
- Skin should be gently washed with a mild cleanser and/or infant wipe and patted dry or air-dried. Vigorous rubbing of the skin or use of washcloths may cause further irritation and skin breakdown.

- Frequent diaper changes are helpful in minimizing exposure to irritants.
- If feasible, remove diaper and expose skin to air to avoid friction and trapped moisture.
- Routine use of a barrier ointment and pastes such as zinc oxide with each diaper change is recommended. Barriers should be applied thickly and can be covered with petroleum jelly to prevent sticking to the diaper.
- Candidal infections should be treated with topical antifungal cream such as nystatin, miconazole, ketoconazole, or clotrimazole cream.
- If secondary bacterial infection is present, topical antibiotics such as mupirocin or oral antibiotics are necessary. Neomycin and bacitracin can incite an allergic contact dermatitis, so they should be avoided.
- Low-potency topical steroids, such as hydrocortisone and hydrocortisone acetate, may be used sparingly in moderate to severe cases.
- Topical application of sucralfate suspension can be useful in recalcitrant cases. It acts as a physical barrier and has antibacterial activity.

ALERT

- Mid- to high-potency topical corticosteroids should not be used because absorption is increased in areas of thin skin and under occlusion. Skin atrophy or systemic effects may result.
- Similarly, prolonged use of any potency topical steroids (>7 days) in the diaper area should be avoided.
- Combination topical corticosteroids and antifungal creams should not be used because these contain mid- to high-potency corticosteroids. Separate corticosteroid and antifungal creams allow the discontinuation of corticosteroid earlier (when the rash starts to improve) while continuing antifungal until rash resolves.
- Products containing boric acid, camphor, phenol, benzocaine, and salicylates should be avoided because of the potential for systemic toxicity.
- Use of powders such as talcum is controversial. Powders can reduce moisture and friction but pose the risk of accidental aspiration.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

With proper care, the rash should improve within 4–7 days. If it does not resolve with appropriate treatment, other causes must be sought.

PROGNOSIS

- Diaper dermatitis usually resolves with the institution of appropriate skin care and the treatment of any underlying cause.
- Irritant diaper dermatitis resolves once the child is potty trained.

COMPLICATIONS

- Generally no longer term complications, although secondary bacterial or fungal infections may lead to ulceration.
- Chronic topical corticosteroid use in diaper area may lead to skin atrophy or systemic effects.
- Some experience postinflammatory hypo- or hyperpigmentation that is typically self-limited.

- B37.2 Candidiasis of skin and nail

FAQ

- Q: Should I switch from cloth to disposable diapers?
- A: This is controversial, although there are some studies that indicate that the superabsorbent disposable diapers may be better for preventing diaper rashes. Cloth diapers used with plastic outer layer probably irritate the skin more because they trap moisture against the skin. Frequent changing of diapers and the use of a barrier paste are very helpful in preventing diaper rash.
- Q: Is the diaper rash due to not keeping the skin clean enough?
- A: Although stool and urine may release enzymes that help break down skin integrity, vigorous and frequent scrubbing with relatively abrasive materials on the damaged skin can be more harmful. This rough cleaning allows introduction of bacteria and yeast into the skin and results in a diaper rash. Gentle cleaning materials should be used. It is not usually necessary to clean the skin of barrier ointments every time; rather, patting the infant dry with a soft cloth or baby wipe, gently reapplying barrier products, and then replacing the diaper is all that is generally required.

DIAPHRAGMATIC HERNIA (CONGENITAL)

Ngoc P. Ly • Fiona Marion

BASICS

DESCRIPTION

- Defect in the diaphragm allowing herniation of abdominal contents into the thoracic cavity, causing varying degrees of pulmonary hypoplasia
- There are 4 types of congenital diaphragmatic hernia (CDH):
 - Bochdalek hernia (posterolateral location)
 - Morgagni hernia (lateral retrosternal location)
 - Pars sternalis (medial retrosternal)
 - Anterolateral

EPIDEMIOLOGY

- 1:2,000–5,000 live births
- Left sided in 85–90%
- Right-sided and bilateral defects less common
- Familial recurrence 2%

PATHOPHYSIOLOGY

- Diaphragm arises from 4 elements and is complete by 8 weeks' gestation.
 - Septum transversum, which becomes the central tendon of the diaphragm
 - Pleuroperitoneal membranes, which extend from the lateral body wall and fuse with the septum transversum and esophageal mesentery
 - Mesentery of the esophagus, which becomes the crura of the diaphragm
 - Lateral body wall from which myocytes migrate to muscularize the diaphragm
- Posterolateral (Bochdalek defect) in 70%, anterior (Morgagni) in 25–30%, central in 2–5%
- Main problem concerns pulmonary hypoplasia, which results in

pulmonary hypertension.

- Smaller lungs with fewer airway branches, fewer alveoli per terminal lung unit, and decreased surfactant production
- Decreased pulmonary vascular surface area and smaller muscular arterioles with abnormal vasoreactivity results in pulmonary hypertension.
- Both ipsilateral and contralateral lungs are hypoplastic, worse on ipsilateral side.
- Degree of pulmonary hypoplasia and pulmonary hypertension determines illness severity both in acute and chronic settings.

ETIOLOGY

- Unknown
- Experimental rat models suggest role of vitamin A deficiency in pathogenesis.

COMMONLY ASSOCIATED CONDITIONS

- 40–50% of cases associated with another type of congenital malformation
 - Cardiac: 10–35%
 - Genitourinary: 23%
 - Gastrointestinal malformations: 14%
 - Central nervous system abnormalities: 10%
- Estimated that 10% of patients with associated congenital anomalies have a syndrome
- Associated syndromes include Beckwith-Wiedemann and trisomies 13, 18, and 21.

DIAGNOSIS

HISTORY

- Prenatal imaging and follow-up testing:
 - CDH detected by prenatal ultrasound in >70% cases
 - Larger defects easier to detect by ultrasound. Thus, prognosis is poorer in those CDH cases detected antenatally.
 - Magnetic resonance imaging (MRI) can be used to confirm the

diagnosis and may predict degree of pulmonary hypoplasia by estimation of lung volume.

- Amniocentesis and genetic consultation to screen for chromosomal anomalies advised
- Important to evaluate for associated congenital abnormalities to guide management
- During the prenatal period, the degree of pulmonary hypoplasia and thus prognosis may be determined by the following:
 - Observed/expected lung-to-head ratio as determined by ultrasound
 - Observed/expected fetal lung volume ratio by fetal MRI
 - Presence of liver in thorax implies worse prognosis.
- Fetal surgery is a possibility for large lesions; however, results have been disappointing.
- Postnatal history
 - Large defects present at birth with respiratory distress.
 - May be easily identified on chest radiograph; however, CT scan may be required to confirm the diagnosis.
 - Smaller defects may be undetected until late childhood/adolescence or even adulthood.
 - Symptoms may include the following:
 - Recurrent cough
 - Recurrent chest infections
 - Intestinal obstruction
 - Feeding intolerance

PHYSICAL EXAM

- Scaphoid abdomen (abdominal contents in thoracic cavity) and asymmetry of chest wall
- Decreased breath sounds with dullness to percussion on the affected side
- Bowel sounds heard in the chest
- Heart sounds shifted to the contralateral chest

DIAGNOSTIC TESTS & INTERPRETATION

Imaging

- Chest radiograph (CXR)

- Opacified hemithorax with contralateral shift of mediastinum
- Decreased lung volumes
- Esophageal portion of nasogastric tube deviated toward opposite side
- May see loops of bowel in the thoracic cavity
- Bowel remaining in the abdomen usually gasless

ALERT

- CXR findings in the newborn period may be subtle. In addition, small CDH defects may present outside of newborn period.
- Echocardiogram
 - Right ventricular function is an important determinant of illness severity.
 - Can estimate degree of pulmonary hypertension
 - Determine presence of associated congenital cardiac defects

Lab

- Arterial blood gas
 - PO₂ low: reflects significant hypoxemia
 - PO₂ high: reflects inadequate ventilation
 - pH, bicarbonate, lactate: acid–base balance
- Karyotype: to assess for associated syndromes and chromosomal abnormalities

DIFFERENTIAL DIAGNOSIS

- Pulmonary
 - Pulmonary sequestration
 - Congenital pulmonary airway malformation (CCAM)
 - Pneumatocele
 - Pulmonary cyst
 - Diaphragmatic eventration
 - Hiatal hernia
 - Congenital lobar emphysema
 - Pulmonary agenesis
 - Anterior mediastinal mass
 - Pneumonia

- Atelectasis
- Pleural effusion
- Pneumothorax
- Cardiac
 - Dextrocardia
 - Congenital heart disease

TREATMENT

ACUTE

General Measures

- Aim for delivery of infant in the hospital where defect is to be repaired as this situation is associated with better outcomes.
- Insertion of a nasogastric tube to decompress herniated contents and allow venting
- Mechanical ventilation
 - Avoid bag and mask ventilation.
 - Goal is to limit barotrauma, maintain peak pressures ≤ 25 mm Hg and positive end-expiratory pressure (PEEP) of at least 5 mm Hg
 - Permissive hypercapnia: tolerate PaCO_2 up to 60 mm Hg
 - Aim for preductal oxygen saturation $>85\%$
 - Consider high-frequency oscillatory ventilation and extracorporeal membrane oxygenation (ECMO) when earlier measures are not effective (e.g., pH <7.25 , $\text{PaCO}_2 >60$ mm Hg, preductal saturation $<85\%$ on FiO_2 0.6)
- Cardiovascular support
 - In setting of pulmonary hypertension, aim for higher mean arterial blood pressure.
- Pulmonary hypertension
 - Severity predicts outcome.
 - 50% of patients are responsive to inspired nitric oxide (iNO), but the effect may be temporary. iNO has no influence on overall outcome.
 - Sildenafil: Phosphodiesterase 5 inhibitor may be used as an adjunct

to iNO to prevent rebound hypertension when weaning iNO or in management of chronic pulmonary hypertension.

- In setting of left ventricular dysfunction with a right ventricle–dependent systemic circulation, milrinone and prostaglandin may be used to decrease afterload and maintain ductal patency.

ALERT

- It is important to assess and treat pulmonary hypertension.
- Avoid aggressive ventilation. It is important to minimize barotrauma.

Surgical Correction

- Delaying surgery until infant is stabilized has been associated with better outcome.
- Primary repair versus prosthetic patch
- Minimally invasive thoracoscopic approach now possible, although is associated with an increased recurrence rate compared with the open approach
- Up to 50% will require patch repair of diaphragmatic defect.
- Recurrence of hernia occurs in up to 50% of patch closures.
- Patch closure of abdomen or creation of surgical silo may be required with very large defects.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Long-term multidisciplinary follow-up required to monitor for complications and recurrence of hernia
- Pulmonary
 - Chronic lung disease: Up to 50% require supplemental oxygen at 28 days and 16% at the time of discharge from hospital.
 - Prevalence of long-term pulmonary morbidity unclear—some series report chronic pulmonary symptoms in up to 50% of survivors.
 - Spirometry shows obstructive pattern of lung disease.
 - Scoliosis and chest wall defects may cause restrictive lung disease.
- Gastrointestinal/nutrition
 - Growth failure secondary to chronic lung disease, increased work of

- breathing, gastroesophageal reflux, and oral aversion
- Failure to thrive is common—up to 1/3 require gastrostomy tube
 - Gastroesophageal reflux (45–90%): may lead to recurrent bronchitis, worsening bronchopulmonary dysplasia, aspiration pneumonia. Persists into adulthood. Consider an H₂ blocker in all patients
 - Cardiac
 - Pulmonary hypertension may persist in up to 30%.
 - Neurodevelopmental
 - Behavioral, cognitive, and motor problems common
 - Greater risk in those with large defects or those requiring ECMO
 - Sensorineural hearing loss
 - Incidence varies: up to 40% described by some
 - Underlying cause unknown
 - Deficit is progressive, so regular long-term follow-up is recommended.
 - Surgical
 - Orthopedic: pectus deformity and scoliosis
 - Recurrence of hernia (in up to 50%): risk greater in those who required patch closure
 - May present with vomiting, bowel obstruction, pulmonary symptoms, or may be asymptomatic
 - Serial CXR recommended for screening

ALERT

- Recurrence of CDH is common and typically presents with vague gastrointestinal symptoms (in contrast to a dramatic presentation of the newborn period).
- Hearing impairment may be progressive. Therefore, serial screening through childhood is essential.

PROGNOSIS

- Depends on the degree of pulmonary hypoplasia and pulmonary hypertension
- 70% postnatal survival, with up to 90% survival described by some centers

- 50% survival in those requiring ECMO
- Prematurity associated with worse prognosis

CODES

ICD10

- Q79.0 Congenital diaphragmatic hernia
- Q33.6 Congenital hypoplasia and dysplasia of lung

FAQ

- Q: What is the recurrence rate?
- A: Reported rates of recurrence vary from 10 to 50%. Serial screening with CXR and a high index of suspicion is necessary. The typical presentation includes emesis, gastrointestinal obstruction, or respiratory symptoms.
- Q: Is pulmonary impairment lifelong?
- A: Although pulmonary function improves with growth, studies

(spirometry, plethysmography, ventilation–perfusion [V/Q] scanning) show persisting deficits. Most patients report decreased pulmonary morbidity/symptoms with increasing age.

- Q: What follow-up is necessary?
- A: Long-term multidisciplinary follow-up is essential. Complications involving multiple organ systems are common.
- Q: Why is long-term gastrointestinal follow-up necessary?
- A: Although complications such as failure to thrive and oral aversion are less common with increasing age, the risk of reflux is lifelong. Treatment into adulthood may be required to control reflux and prevent Barrett esophagus.

DIARRHEA

Roberto Gugig

BASICS

DESCRIPTION

- Diarrhea is an increase in frequency, volume, or fluidity of a patient's stool as compared to the normal bowel movement pattern.
- On the basis of its duration, diarrhea can be classified as acute (<14 days), persistent (14–29 days), or chronic (> 30 days).
- Acute diarrhea typically presents abruptly with increased fluid content of the stool >10 mL/kg/day and lasts <14 days. Usually involves the passage of >250 g/day of unformed stool
- Persistent diarrhea can also begin acutely, but last for ≥ 14 days.
- Diarrhea is caused whenever there is disruption of the normal absorptive and secretory functions of intestinal mucosa resulting in water and electrolyte imbalance.
- Malabsorption, maldigestion, cellular electrolyte pump dysfunction, and intestinal colonization or invasion by microorganisms can cause diarrhea.
- Tenesmus, perianal discomfort, and incontinence may occur with all diarrhea.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Acute diarrhea

- Dietary causes
 - Sorbitol, fructose, lactose, and intolerance to specific foods (beans, fruit, peppers, etc.)
- Infectious causes:
 - Bacterial (e.g., *Escherichia coli*, *Clostridium difficile*) and viral (e.g., rotavirus, Norwalk agent, adenovirus)
 - Parasites (*Giardia*, *Cryptosporidium*, *Entamoeba*)

- Medications
 - Antibiotics, laxatives
- Vitamin deficiency
 - Zinc, niacin

Chronic diarrhea

- Allergic/autoimmune
 - Milk/soy protein allergy, eosinophilic enteritis, Henoch-Schönlein purpura (HSP), celiac disease, or autoimmune enteropathy
- Immunodeficiency
 - HIV/AIDS, chronic granulomatous disease, hyper IgM, severe combined immunodeficiency
- Anatomic abnormalities
 - Short intestinal tract (e.g., h/o necrotizing enterocolitis, Hirschsprung, malrotation, inflammatory bowel disease)
- Bile acid malabsorption
- Congenital
 - Cystic fibrosis, microvillus inclusion disease, tufting enteropathy, or IPEX syndrome
- Encopresis
- Endocrine disorders
 - Hyperthyroidism, diabetes, congenital adrenal hyperplasia
- Bacterial overgrowth (e.g., blind loop, ostomy)
- Inflammatory bowel disease
 - Ulcerative colitis, Crohn disease
- Intestinal lymphangiectasia
 - Primary and secondary
- Irritable bowel syndrome
- Lactose intolerance
 - Primary, secondary, and congenital
- Pancreatic exocrine dysfunction
 - Shwachman-Diamond syndrome, cationic trypsinogen deficiency, Jeune syndrome, Pearson syndrome, and Johanson-Blizzard syndrome
- Postinfectious enteropathy
- Secretory tumors

- VIPoma, somatostatinoma, gastrinoma, carcinoid, glucagonoma

APPROACH TO PATIENT

- The first step in the clinical appraisal of the patient with diarrhea is to identify what the patient “means” by diarrhea; exclude the possibility of fecal incontinence; rule out drug-induced diarrhea; distinguish acute from chronic; categorize as inflammatory, fatty, or watery; and consider the possibility of factitious diarrhea.
- It is important to determine the type of diarrhea (osmotic vs. secretory), as this will alter your diagnostic and therapeutic plan.
 - Secretory diarrhea
 - Absorption of intestinal fluid and electrolytes is accomplished through multiple cellular pumps transporting sodium, glucose, and amino acids.
 - Factors that interrupt these pumps (e.g., cholera toxin, prostaglandin E, vasoactive intestinal peptide, secretin, acetylcholine) can cause a severe active isotonic secretory state manifested by profuse diarrhea, dehydration, and acidosis. Other causes include bile acid malabsorption, inflammatory bowel disease, disordered regulation (postvagotomy, diabetic neuropathy), peptide-secreting endocrine tumors, and neoplasia (colon carcinoma, lymphoma, villous adenoma).
 - Osmotic diarrhea
 - In general, the solute composition of intestinal fluid is similar to that of plasma.
 - Osmotic diarrhea occurs when poorly absorbed or nonabsorbable solute is present in the intestinal lumen (this may result in low stool pH <6).
 - This can occur with the ingestion of nonabsorbable sugars (e.g., sorbitol), cathartics (e.g., magnesium citrate), carbohydrate malabsorption secondary to mucosal damage (e.g., lactose), maldigestion (e.g., pancreatic dysfunction), rapid transit of intestinal fluid, or with a rare congenital transport defect.

HISTORY

- **Question:** Duration? (<14 days, >30 days)

Significance: A distinction should be made between acute and chronic diarrhea. The cause of acute diarrhea is almost always related to an infection, a medication, or the addition of a new food.

- **Question:** Travel history?

Significance: Questions should be asked regarding travel to areas where drinking water is contaminated (e.g., *Entamoeba* in Mexico) or food handling/preparation is prolonged or unsanitary (e.g., *Campylobacter*, *Bacillus cereus*, or *E. coli*). Exposure to freshwater streams or ponds (e.g., *Cryptosporidium*, *Giardia*) may also be important to address.

- **Question:** Recent use of antibiotics?

Significance: A variety of antibiotics can be associated with *C. difficile* colitis or antibiotic-related diarrhea.

- **Question:** Adolescents?

Significance: Questions should be asked regarding body image and weight. Laxative abuse causing an osmotic diarrhea is common among adolescents who have an eating disorder or athletes attempting to lose weight rapidly.

- **Question:** Family history?

Significance: conditions with genetic susceptibility (e.g., inflammatory bowel disease, celiac disease)

- **Question:** Systemic symptoms?

Significance: It is important to ask about concomitant fever, GI bleeding, rashes, or vomiting. Certain GI infections and inflammatory bowel disease have specific associated systemic symptoms.

- **Question:** Hematochezia?

Significance: The occurrence of acute, bloody stools and fever generally indicates a bacterial infection. However, these same symptoms coupled with fatigue, poor urine output, and history of easy bruising may suggest hemolytic uremic syndrome. Bloody stools in combination with a history of crampy abdominal pain, arthritis, and purpuric rash can indicate HSP, a completely different entity. Chronic bloody diarrhea, abdominal pain, and weight loss are characteristic of inflammatory bowel disease.

- **Question:** Steatorrhea? (greasy or bulky stools)

Significance: indicates fat malabsorption (e.g., cystic fibrosis)

- **Question:** Age? (congenital vs. acquired)

Significance: The age of the child is important because a number of diseases present between birth and 3 months of life including cystic fibrosis, milk or soy protein allergy, and congenital enteropathies.

- **Question:** Previously well infant with recent viral illness and subsequent protracted diarrhea?

Significance: Postviral enteritis should be suspected. This disorder is characterized by severe mucosal injury resulting in transient disaccharidase deficiency and potentially prolonged malabsorption.

- **Question:** Normal preschool-aged children who have 2–10 watery stools per day without other symptoms and/or cause who have increased juice intake?

Significance: Chronic nonspecific diarrhea of childhood or “toddler’s diarrhea” should be considered.

- **Question:** Lactose intolerance?

Significance: commonly occurs in many older children and adults, with >95% occurrence rate in some ethnic groups

- **Question:** Chronic diarrhea with weight loss?

Significance: Inflammatory or immunologic disorders such as ulcerative colitis, Crohn disease, and celiac disease must be ruled out. Celiac disease is an immune-mediated enteropathy caused by a permanent sensitivity to gluten and related prolamins in genetically susceptible individuals. Occurs in ~1:130 of the U.S. population with a genetic predisposition and should be considered in any child with chronic diarrhea and poor weight gain

PHYSICAL EXAM

- **Finding:** Child’s growth parameters?

Significance: Previous measurements and growth curves are necessary to make an accurate evaluation. Findings of a chronically malnourished child with years of weight loss or poor growth velocity would indicate a divergent differential diagnosis from that of a healthy-appearing child with a history of normal growth.

- **Finding:** Arthritis and rash?

Significance: Diarrhea accompanied by these signs can occur in

diseases such as inflammatory bowel disease, celiac disease, HSP, and specific bacterial infections.

- **Finding:** Oral ulcers?
Significance: occur in inflammatory bowel disease and celiac disease
- **Finding:** Hydration?
Significance: Capillary refill >3 seconds, tachycardia without pain or fever, and dry mucous membranes provide clues to dehydration.
- **Finding:** Nail bed clubbing?
Significance: This finding may direct questioning to rule out cystic fibrosis or chronic inflammatory bowel disease.
- **Finding:** Masses?
Significance: A right lower quadrant mass could suggest an abscess (e.g., terminal ileitis in Crohn disease or appendiceal abscess) or intussusception (e.g., irritable child with currant jelly-like stools).

DIAGNOSTIC TESTS & INTERPRETATION

- **Test:** stool culture
Significance: Stool examination for blood, mucus, inflammatory cells, and microorganisms is an important first step in determining the cause of the diarrhea. Stool cultures for parasites (e.g., Giardia, Cryptosporidium, Entamoeba), bacterial pathogens (e.g., Salmonella, Campylobacter, Shigella, Yersinia, Aeromonas, Plesiomonas), viral particles, and C. difficile toxin should be appropriately obtained in all children with unexplained diarrhea.
- **Test:** stool pH and reducing substances
Significance: These tests are useful in identifying carbohydrate malabsorption. A stool pH <5–6 and stool-reducing substances >0.5–1% is suggestive of malabsorption.
- **Test:** stool osmolality and electrolytes
Significance: Stool osmolality, stool Na, and stool K can be used to calculate an ion gap and differentiate between secretory and osmotic diarrhea.
 - Stool osmotic gap = measured stool osmolality – estimated stool osmolality
 - Estimated stool osmolality = $2 (\text{Na stool} + \text{K stool})$
 - An increased stool osmotic gap is >50 mOsm/kg.

- **Test:** Hemoccult
Significance: Sensitive and specific test is helpful in distinguishing truly heme-positive stools from ingested foods/drinks with artificial or natural red coloring. Stool positive for blood is suggestive of infectious (*C. difficile*) and organic etiologies (inflammatory bowel disease).
- **Test:** 72-hour quantitative fecal fat evaluation
Significance: This is a sensitive test for steatorrhea. Patients need to be placed on a high-fat diet (2–4 g/kg) for a minimum of 1 day prior to testing.
 - Over 3 days, all stool is collected, refrigerated, and tested. A diet record needs to be performed for the 3 days that correspond to the stool collection period.
 - The coefficient of fat absorption is calculated: $\frac{\text{grams of fat ingested} - \text{grams of fat excreted}}{\text{grams of fat ingested}} \times 100$.
 - Normal values are as follows:
 - Premature infants: 60–75%
 - Newborns: 80–85%
 - Children 10 months to 3 years: 85–95%
 - Children >3 years: 93%.
 - When fat malabsorption is present, disorders of pancreatic function (e.g., cystic fibrosis, Shwachman-Diamond syndrome) or severe intestinal disease should be suspected.
- **Test:** lactose breath test
Significance: This noninvasive test measures hydrogen levels and or methane. It is based on the principle that hydrogen gas is produced by colonic bacterial fermentation of malabsorbed carbohydrates. When abnormal in older healthy-appearing children, primary lactase deficiency is likely. However, in young children, a secondary lactase deficiency should be considered and small-bowel disease should be ruled out.
- **Test:** D-xylose test
Significance: This serum test is an indirect measure of functional small bowel surface area. D-xylose absorption in the blood occurs independent of bile salts, pancreatic enzymes, and intestinal disaccharidases. A specific dose of D-xylose (1 g/kg, maximum 25 g)

is given orally after an 8-hour fast, and the serum level of D-xylose is determined after 1 hour. Levels <15–20 mg/dL in children is abnormal and suggestive of disorders that alter or disrupt intestinal mucosa absorption.

- **Test:** fecal calprotectin
Significance: Calprotectin is a neutrophilic protein detected in stools in inflammatory conditions.
- **Test:** endoscopy and colonoscopy
Significance: Direct visualization of the intestinal mucosa as well as intestinal culture, disaccharidase collection, and biopsies can provide clues to diagnosis.
- **Test:** celiac panel
Significance: This includes a tissue transglutaminase, IgA level, and endomysial antibody.

TREATMENT

GENERAL MEASURES

- The key elements in treatment of diarrhea are as follows: (a) correction of hydration, (b) correction of electrolytes, and (c) specific treatment of underlying cause when indicated.
- Rehydration is the cornerstone of treatment.
- Oral rehydration therapy with glucose concentrations of 111 mmol/L and 90 mmol/L sodium is recommended.
- IV rehydration is indicated for patients who are severely dehydrated and unable to tolerate oral feedings.

ISSUES FOR REFERRAL

Children who present with growth failure, noninfectious heme-positive diarrhea, or unexplained chronic diarrhea should be considered for referral to a pediatric gastroenterologist.

INPATIENT CONSIDERATIONS

Initial Stabilization

Diarrhea can lead to significant dehydration and electrolyte imbalance. Any child suspected of clinical dehydration should be closely observed.

Only if oral rehydration is ineffective is IV therapy indicated. Culture-negative GI bleeding associated with severe abdominal pain and diarrhea should always be treated urgently.

- Antibiotics
 - *Vibrio cholerae*, *Shigella*, and *Giardia lamblia* require antimicrobial therapy (i.e., trimethoprim/sulfasoxazole, azithromycin, tetracycline, ciprofloxacin, metronidazole).
 - Prolonged courses of enteropathogenic *E. coli*, *Yersinia* in sickle cell patients, and *Salmonella* species infections in the very young febrile or bacteremic infant require antimicrobial therapy.

ONGOING CARE

DIET

- Breastfeeding should continue during episodes of gastroenteritis, as it promotes mucosal healing and recovery.
 - It was traditionally believed that bowel rest was beneficial for formula-fed infants.
 - Many studies have now shown that return feeding after 4–6 hours promotes a faster recovery.
- Micronutrient supplementation
 - Zinc supplementation at a dose of 20 mg/day for children older than 6 months and 10 mg/day in those younger than 6 months for 10–14 days during episodes of acute diarrhea has been shown to decrease severity and duration as well as preventing future episodes in malnourished children.
- Probiotics and Prebiotics
 - Have been used for both prevention and treatment of diarrhea
 - *Lactobacillus rhamnosus* GG has been shown to shorten the duration of diarrheal illness and viral shedding (e.g., rotavirus).
 - May help patients with Crohn disease, ulcerative colitis, irritable bowel syndrome, and pouchitis

- A09 Infectious gastroenteritis and colitis, unspecified

DIPHTHERIA

Michael J. Smith

BASICS

DESCRIPTION

Acute infectious disease caused by *Corynebacterium diphtheriae*; affects primarily the membranes of the upper respiratory tract with the formation of a gray-white pseudomembrane

EPIDEMIOLOGY

- The only known reservoir for *C. diphtheriae* is humans; disease is acquired by contact with either a carrier or a diseased person.
- Most cases occur during the cooler autumn and winter months in individuals <15 years of age who are unimmunized.
- Recent outbreaks have occurred, most notably in the countries of the former Soviet Union, and supply additional evidence that disease occurs among the socioeconomically disadvantaged living in crowded conditions.

Incidence

- Although the disease is distributed throughout the world, it is endemic primarily in developing regions of Africa, Asia, and South America.
- In the Western world, the incidence of diphtheria has changed dramatically in the past 50–75 years as a result of the widespread use of diphtheria toxoid after World War II.
- The incidence has declined steadily and is now a rare occurrence.

GENERAL PREVENTION

Active immunization with diphtheria toxoid is the cornerstone of population-based diphtheria prevention. Current recommendations from the Advisory Committee on Immunization Practices (ACIP) of the Centers for Disease Control and Prevention (CDC) are as follows:

- Ages 2 months–7 years: 5 doses of diphtheria vaccine (with tetanus toxoid and acellular pertussis)
 - First 3 given as DTaP vaccine 0.5 mL IM at 2-month intervals

- beginning at 2 months of age
- 4th dose of DTaP should be given at 15–18 months of age.
- 5th dose of DTaP at 4–6 years of age
- In 2005, 2 tetanus toxoid, reduced diphtheria toxoid, and acellular pertussis (Tdap) vaccines were licensed for use in adolescents 11–18 years of age.
- 1 booster dose of Tdap should be given to all adolescents at the 11–12-year-old visit, provided they have completed the childhood series. Subsequent tetanus and diphtheria (Td) boosters should be administered every 10 years.
- Tdap should replace the 1st dose of Td in children 7–10 years of age who are undergoing primary immunization.
- Isolation of patients with diphtheria is required until culture from the site of infection is negative on 2 consecutive specimens.

PATHOPHYSIOLOGY

- The initial entry site for *C. diphtheriae* is via airborne respiratory droplets, typically the nose or mouth but occasionally the ocular surface, genital mucous membranes, or preexisting skin lesions.
- Following 2–4 days of incubation at one of these sites, the bacterium elaborates toxin.
- Locally, the toxin induces formation of a necrotic coagulation of the mucous membranes (pseudomembrane) with underlying tissue edema; respiratory compromise may ensue.
- Elaborated exotoxin may also have profound effects on the heart, nerves, and kidneys in the form of myocarditis, demyelination, and tubular necrosis, respectively.

ETIOLOGY

C. diphtheriae, a gram-positive pleomorphic bacillus

DIAGNOSIS

- Respiratory tract diphtheria
 - Nasal diphtheria starts with mild rhinorrhea that gradually becomes serosanguineous, then mucopurulent, and often malodorous; it

occurs most often in infants.

- Tonsillar and pharyngeal diphtheria begin with anorexia, malaise, low-grade fever, and pharyngitis.
 - A membrane appears within 1–2 days.
 - Cervical lymphadenitis and edema of the cervical soft tissues may be severe.
 - Disease course varies with extent of toxin elaboration and membrane production.
 - Respiratory and cardiovascular collapse may occur.
- Laryngeal diphtheria most often represents extension of a pharyngeal infection.
 - Clinically presents as typical croup
 - Acute airway obstruction may occur.
 - In severe cases, the membrane may invade the entire tracheobronchial tree.
- Cutaneous diphtheria occurs in warmer tropical regions.
 - It is characterized by chronic nonhealing ulcers with gray membrane.
 - May serve as a reservoir in endemic and epidemic areas of respiratory diphtheria
- Other sites: Rarely, vulvovaginal, conjunctival, or aural forms occur.

HISTORY

- Exposure to an individual with diphtheria is not necessarily elicited because contact with an asymptomatic carrier may be the only source of infection.
- Incubation period
 - Incubation period is 1–6 days.
 - Respiratory diphtheria, depending on the site of infection, may begin with nasal discharge alone or with pharyngitis accompanied by mild systemic symptoms.
 - Progression of symptoms thereafter occurs as outlined earlier (see “[Diagnosis](#)”).
- Previous diphtheria immunization history, diphtheria exposure

PHYSICAL EXAM

- Classic findings
 - Nasal discharge
 - Nasal or pharyngeal membrane
 - Heart rate out of proportion to body temperature
 - Respiratory distress
 - Stridor
 - Cough
 - Hoarseness
 - Palatal paralysis
 - Neck swelling
 - Cervical lymphadenitis
 - Attempt to remove any membrane present results in bleeding.
- Conjunctival diphtheria: palpebral conjunctival involvement with a red, edematous, membranous appearance
- Aural diphtheria: otitis externa with a purulent, malodorous discharge
- Cutaneous diphtheria: See “[Diagnosis](#).”

DIAGNOSTIC TESTS & INTERPRETATION

Diagnosis should be on clinical grounds: Delay in treatment increases morbidity and mortality.

Lab

- Culture of material from the membrane or beneath the membrane. Because special growth media are required, the lab should be notified of suspicion of diphtheria.
- If a strain of *C. diphtheriae* is isolated, additional testing for presence or absence of toxin production should be done by a laboratory prepared to conduct an animal neutralization test or, alternatively, neutralization (with antitoxin) in tissue culture.

DIFFERENTIAL DIAGNOSIS

- Nasal diphtheria
 - Common cold
 - Nasal foreign body
 - Sinusitis
 - Adenoiditis
 - Snuffles (congenital syphilis)

- Tonsillar or pharyngeal diphtheria
 - Streptococcal pharyngitis
 - Infectious mononucleosis
 - Primary herpetic tonsillitis
 - Thrush
 - Vincent angina
 - Posttonsillectomy faucial membranes
 - Oropharyngeal involvement caused by toxoplasmosis, cytomegalovirus, tularemia, and salmonellosis
- Laryngeal diphtheria
 - Croup
 - Acute epiglottitis
 - Aspirated foreign body
 - Peripharyngeal and retropharyngeal abscess
 - Laryngeal papillomas
 - Other masses

TREATMENT

MEDICATION

Antibiotic therapy: Use in addition to, not in place of, diphtheria antitoxin (DAT).

- Respiratory diphtheria
 - Penicillin G
 - Aqueous crystalline 100,000–150,000 U/kg/24 h in 4 divided doses for 14 days or
 - Procaine 25,000–50,000 U/kg/24 h in 2 divided doses for 14 days or
 - Erythromycin 40–50 mg/kg (maximum 2 g/24 h) PO or parenterally for 14 days
- Cutaneous diphtheria: requires local care of the lesion with soap and water and administration of antimicrobials for 10 days

INPATIENT CONSIDERATIONS

Initial Stabilization

- DAT antiserum, produced in horses, must be administered as soon as possible. DAT is available from the CDC. (Note: For patients with known horse serum sensitivity, a test dose should be administered first; if positive, the patient should be desensitized.)
- Pharyngeal or laryngeal disease of <48 hours duration: 20,000–40,000 U IV
- Nasopharyngeal lesions: 40,000–60,000 U IV
- Extensive disease of ≥ 3 days' duration or diffuse neck swelling: 80,000–120,000 U IV

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Mild cases: After membrane sloughs off in 7–10 days, recovery is usually uneventful.
- More severe cases: Recovery may be slower; serious complications may occur.

PROGNOSIS

- Most strongly dependent on the immunization status of the host. Those without prior adequate immunization have significantly higher morbidity and mortality.
- Delay in onset of treatment also increases mortality.
 - When appropriate treatment has been administered on day 1 of illness, mortality may be as low as 1%.
 - When treatment has been delayed until day 4, the mortality rate is ≤ 20 -fold higher.
- Organism virulence: Toxigenic strains are associated with more severe disease and a poorer prognosis.
- Location of membrane: Laryngeal diphtheria has a higher mortality due to airway obstruction.
- A megakaryocytic thrombocytopenia and WBC count <25,000 are associated with poor outcome.

COMPLICATIONS

- Cardiac toxicity: Myocarditis may develop secondary to elaborated

toxin anytime between the 1st and 6th week of illness. Although cardiac failure may occur, most cases are transient.

- Neurologic toxicity occurs secondary to toxin elaboration and mainly reflects bilateral motor involvement.
- Paralysis of the soft palate is most common, but ocular paralysis, diaphragm paralysis, peripheral neuropathy of the extremities, and loss of deep tendon reflexes also occur.
- The frequency of all complications, including those listed above, increases with increasing time between symptom onset and antitoxin administration and also with extent of membrane formation.

CODES

ICD10

- A36.9 Diphtheria, unspecified
- A36.1 Nasopharyngeal diphtheria
- A36.3 Cutaneous diphtheria

FAQ

- Q: What is the incidence of diphtheria in the United States?
- A: No locally acquired case of respiratory diphtheria has been reported in the United States since 2003. Cutaneous diphtheria still occurs but is not a reportable disease.
- Q: Are there currently places in the world where diphtheria is a problem?
- A: Yes. An epidemic began in 1990 in Russia, spread in 1991 to Ukraine, and during 1993 and 1994 spread to the remaining countries of the former Soviet Union. Other endemic regions include the Middle East and Asia and some countries in Africa and Central and South America. Travelers to these regions should check the CDC Web site for the latest information.
- Q: What precautions should be taken by travelers to areas of the world with diphtheria outbreaks?
- A: The ACIP recommends that travelers to such areas be up-to-date with diphtheria immunization. Infants traveling to areas where diphtheria is endemic or epidemic should ideally receive 3 doses of DTaP before travel.

DISKITIS

Melissa L. Mannion • Randy Q. Cron

BASICS

DESCRIPTION

Often benign, self-limited inflammatory process of an intervertebral disk

EPIDEMIOLOGY

>50% of the cases occur in children <4 years of age.

Incidence

- Peak incidence is between 0 and 2 years of age.
- Second peak: >10 years

Prevalence

Rare

PATHOPHYSIOLOGY

- Probably of infectious etiology by an indolent organism
- Usually none identified; occasionally, *Staphylococcus aureus*, *Moraxella*, or the *Enterobacteriaceae* are cultured.

ETIOLOGY

Idiopathic, infectious, or traumatic

DIAGNOSIS

HISTORY

- Uncomfortable, irritable child
- Refusal to walk
- Fever
- Back or abdominal pain
- Symptoms of short duration prior to presentation

PHYSICAL EXAM

- Usually, rigid posture and pain elicited on movement (sits in tripod

position)

- Loss of lumbar lordosis
- Focal tenderness to palpation
- Most common locations: L4–L5 and L3–L4

DIAGNOSTIC TESTS & INTERPRETATION

Lab

Initial lab tests

- Purified protein derivative (PPD)
- WBC count
- Erythrocyte sedimentation rate (ESR)
- C-reactive protein (CRP)
- Blood cultures

Imaging

- Plain radiographic studies
 - Usually normal, although may demonstrate disk narrowing as illness progresses
- MRI
 - Useful to confirm diagnosis and location of pathology
 - Demonstrates disk edema
- Bone scan
 - Demonstrates increased uptake at affected area
 - May be used to screen for other sites of infection

DIFFERENTIAL DIAGNOSIS

- Infection
 - Vertebral osteomyelitis (e.g., Staphylococcus, Salmonella)
 - Pott disease (tuberculous spondylitis)
 - Pyelonephritis
 - Retrocecal appendicitis
 - Psoas or epidural abscess
- Trauma
 - Fracture
 - Disk herniation
- Tumors
 - Osteoid osteoma

- Langerhans cell granulomatosis of the spine
- Vascular: avascular necrosis of vertebral body
- Congenital: spondylolisthesis
- Immunologic
 - Ankylosing spondylitis
 - Nonbacterial osteitis
- Miscellaneous: Scheuermann disease (osteochondritis of the vertebral bodies)

ALERT

There is difficulty distinguishing early vertebral body osteomyelitis from diskitis.

TREATMENT

MEDICATION

- Usually quite responsive to NSAIDs
- Toddlers are usually treated with anti-staphylococcal antibiotics.

COMPLEMENTARY & ALTERNATIVE THERAPIES

- Physical therapy
 - Patient should be immobilized during acute period.
 - Casting may be required.

INPATIENT CONSIDERATIONS

Initial Stabilization

Duration

- Follow CBC, CRP, and ESR.
- Continue treatment until child is asymptomatic.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- When to expect improvement: Most patients are asymptomatic in 6–8 weeks.

- Signs to watch for:
 - Recurrence of symptoms due to reactivation of the disease
 - Progressive loss of disk height
 - Destruction of adjacent vertebral bodies

PROGNOSIS

- Usually excellent
- Scoliosis may occur.
- Radiologic disk space narrowing almost always occurs.

COMPLICATIONS

- Occasionally, scoliosis or kyphosis
- Ankylosis of adjacent vertebrae may occur.

- M46.46 Discitis, unspecified, lumbar region
- M46.42 Discitis, unspecified, cervical region

FAQ

- Q: When are a biopsy and tissue culture indicated?
- A: If there is bony destruction of adjacent vertebral bodies or if clinical course is prolonged or recurrent
- Q: When are antibiotics indicated?
- A: Obviously, in situations with positive cultures or clear infective focus, or if course is atypical or prolonged

DISSEMINATED INTRAVASCULAR COAGULATION

Char Witmer

BASICS

DESCRIPTION

- Disseminated intravascular coagulation (DIC) is an acquired syndrome that is always secondary to an underlying etiology.
- It is a systemic life-threatening process characterized by an uncontrolled activation of the coagulation and fibrinolytic systems with excessive thrombin generation and the consumption of coagulation factors and platelets.
- Widespread deposition of microthrombi can compromise perfusion and lead to organ failure.
- Ongoing activation and consumption of coagulant factors and platelets can result in diffuse and profuse bleeding.

EPIDEMIOLOGY

- Most commonly secondary to infections
- Overall incidence is difficult to determine secondary to the many conditions that cause DIC.

PATHOPHYSIOLOGY

- Not a disorder in itself; occurs as a result of various initiating events
- Characterized by microvascular thrombosis and hemorrhage
- May be acute (e.g., meningococcemia) or chronic (e.g., malignancy/leukemia)
- There is a systemic intravascular deposition of fibrin as a result of increased thrombin generation, suppression of anticoagulant pathways, impaired fibrinolysis, and activation of inflammatory pathways.
- The initiation of coagulation activation leading to thrombin formation in DIC is mediated via the tissue factor/factor VIIa pathway.
- The tissue factor/factor VIIa pathway is activated via tissue factor expression from damaged endothelial cells.

- Anticoagulant pathways are diminished because of a decrease in the plasma levels of antithrombin and the protein C system through impaired production and increased destruction.
- The increase in fibrinolytic activity is likely secondary to the release of plasminogen activators from damaged endothelial cells.

ETIOLOGY

Most common causes are sepsis (particularly gram-negative), hypotensive shock, and trauma.

- Sepsis/severe infection
 - Bacterial: gram-negative and gram-positive
 - Malaria: *Plasmodium falciparum*
 - Fungal: *Aspergillus*
 - Rickettsial: Rocky Mountain spotted fever
 - Viral
- Trauma
 - Multiple fractures with fat emboli
 - Massive soft tissue injury
 - Severe head trauma
 - Multiple gunshot wounds
- Malignancies
 - Acute promyelocytic leukemia
 - Widespread solid tumors (e.g., neuroblastoma, adenocarcinoma)
- Obstetric
 - Retained intrauterine fetal demise
 - Preeclampsia/eclampsia
 - Amniotic fluid embolism
 - Abruptio placentae
 - Posthemorrhagic shock
- Neonatal
 - Necrotizing enterocolitis
 - Perinatal asphyxia
 - Amniotic fluid aspiration
 - Obstetric complications (see above)
 - Sepsis (bacterial and viral)
 - Erythroblastosis fetalis

- Respiratory distress syndrome
- Vascular malformations
 - Kasabach-Merritt syndrome
 - Large vascular aneurysms
- Miscellaneous
 - Acute hemolytic transfusion reaction
 - Snake bite
 - Homozygous protein C/S deficiency (purpura fulminans)
 - Transplant rejection
 - Severe collagen vascular disease
 - Recreational drugs
 - Profound shock or asphyxia
 - Hypothermia or hyperthermia
 - Extensive burn injuries
 - Fulminant hepatitis/hepatic failure
 - Severe pancreatitis

DIAGNOSIS

HISTORY

- Presence of one of the underlying conditions (see “[Etiology](#)”)
- Abrupt onset of bleeding
- Prolonged bleeding from venipuncture sites
- Bleeding from multiple sites, especially venipunctures, cutdown sites, mucous membranes, skin, GI tract, and genitourinary tract
- Pulmonary or intracranial hemorrhage
- Major organ dysfunction: pulmonary, renal, hepatic

PHYSICAL EXAM

- Signs of underlying disease
- Generally, a very toxic-appearing patient
- Ecchymosis and petechiae
- Bleeding from previously intact venipuncture sites or surgical wounds
- Skin infarctions (purpura fulminans) secondary to thrombosis of dermal vessels

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- There is no single test that can reliably diagnose DIC.
- Laboratory testing for DIC should be followed closely because results can change rapidly.
- CBC: Decreased platelet count is often the earliest abnormality, but this finding is nonspecific.
- Peripheral smear: schistocytes, microspherocytes (50% of cases)
- Prothrombin time (PT) and activated partial thromboplastin time (aPTT): normal to prolonged
 - Prolonged PT in 50–75% of cases
 - Prolonged aPTT in 50–60% of cases
- Fibrinogen: in the initial phase is increased as an acute-phase reactant and then decrease with consumption
 - Sensitivity is only 28%
- Fibrin degradation products or fibrin split products: increased
 - Sensitivity 90–100% but low specificity
- Soluble fibrin monomer complexes (D-dimers): increased
 - Elevated D-dimer in 93–100% of patients with DIC but low specificity
 - A normal D-dimer rules out DIC
- Antithrombin, protein C or S levels: decreased
 - Not routinely sent to assess for DIC
- Factor VIII: in the initial phase could be increased as an acute-phase reactant and then decrease with consumption
 - Factor VIII is normal in coagulopathy associated with liver disease.
- Multiple scoring systems using common laboratory results have been developed to help determine if a patient is in DIC. These scoring systems have not been validated in pediatric patients.

DIFFERENTIAL DIAGNOSIS

- Coagulopathy of liver disease
- Vitamin K deficiency
- Pathologic fibrinolysis
- Other microangiopathic diseases, for example, thrombotic thrombocytopenic purpura or hemolytic uremic syndrome

TREATMENT

ADDITIONAL TREATMENT

General Measures

- The most important therapy for DIC is to treat the underlying disorder.
- Supportive therapy may be required to treat symptomatic coagulation abnormalities.
- Hemostatic therapy should not be used to treat isolated laboratory abnormalities.
- Correction of the coagulopathy should only occur to treat bleeding or prior to an invasive procedure.
- Replacement therapy
 - Cryoprecipitate: for fibrinogen replacement
 - Platelets
 - Fresh frozen plasma: contains all pro and anticoagulant proteins
- The role of heparin for DIC is controversial. It has been used in chronic DIC, arterial thromboses, or large vessel venous thromboses.
- Antithrombin at supraphysiologic dosing has been studied with mixed results.
 - Antithrombin is currently not recommended for the treatment of DIC in pediatric patients.
- In pediatric DIC, recombinant activated protein C has not been shown to be beneficial and was associated with an increased risk of bleeding.
- Off-label use of recombinant activated factor VII has been reported for patients with severe bleeding that is refractory to replacement therapy. There are significant concerns about the prothrombotic potential of this medication.
- Antifibrinolytic agents (aminocaproic acid or tranexamic acid) have been used for patients with intense fibrinolysis (e.g., Kasabach-Merritt, acute promyelocytic leukemia, or trauma). These medications are not routinely recommended for the treatment of DIC.
- Supportive care: Manage other organ system failure.

ONGOING CARE

PROGNOSIS

- Poor unless underlying disease is treated
- The intensity and duration of DIC depend on the degree of activation of the coagulation system, liver function, blood flow, and ability to reverse underlying etiology that has led to DIC.

COMPLICATIONS

- Hemorrhage
 - Pulmonary
 - Intracranial
- Thrombosis
- Multiorgan system failure

DOWN SYNDROME (TRISOMY 21)

Esther K. Chung • Julia Belkowitz

BASICS

DESCRIPTION

Syndrome first described by John Langdon Down in 1866 consisting of multiple abnormalities, including hypotonia, flat facies, upslanting palpebral fissures, and small ears; also called “trisomy 21”

Other abnormalities include the following:

- Congenital heart disease (40–50%; most not symptomatic as a newborn)
 - Atrioventricular (AV) canal (60% of those with congenital heart disease)
 - Ventriculoseptal defect (VSD)
 - Patent ductus arteriosus (PDA)
 - Atrioseptal defect (ASD)
 - Aberrant subclavian artery
 - Tetralogy of Fallot
- Hearing loss (66–75%): sensorineural and conductive
- Strabismus (33–45%)
- Nystagmus (15–35%)
- Fine lens opacities (by slit-lamp examination 59%), cataracts (1–15%)
- Refractive errors (50%)
- Nasolacrimal duct stenosis
- Delayed tooth eruption
- Tracheoesophageal fistula
- Gastrointestinal atresia (12%)
- Celiac disease
- Meckel diverticulum
- Hirschsprung disease (<1%)
- Imperforate anus
- Renal malformations
- Hypospadias (5%)

- Cryptorchidism (5–50%)
- Testicular microlithiasis
- Thyroid disease (15%): hypothyroidism, hyperthyroidism
- Transient myeloproliferative disorder (3–10%), neonatal (leukemoid reaction)
- Transient neonatal polycythemia, neutrophilia, thrombocytopenia
- Leukemia (<1%; 10–20 times greater risk than in general population, acute lymphoblastic and myeloid leukemias)
- Decreased T and B lymphocytes
- Testicular germ cell tumors
- Airway anomalies, including tracheo- and laryngomalacia
- Infertility, especially in males
- Obesity
- Alopecia areata (10–15%)
- Seizures (5–10%), usually myoclonic
- Alzheimer disease (nearly all older than age 40 years show neuropathologic signs)
- Mild to moderate mental retardation (IQ range 25–70)
- Dry, hyperkeratotic skin (75%)

EPIDEMIOLOGY

- Male > female (1.3:1)
- Best recognized and most frequent chromosomal syndrome of humans
- 1 of the 3 most common autosomal trisomies in humans (others are trisomies 18 and 13)
- Most common autosomal chromosomal abnormality causing mental retardation
- >50% of trisomy 21 fetuses are spontaneously aborted in early pregnancy.

Incidence

1/600–1/800 live births, although incidence varies with maternal age:

- 1/1,500 for maternal ages 15–29 years
- 1/800 for maternal ages 30–34 years
- 1/270 for maternal ages 35–39 years
- 1/100 for maternal ages 40–49 years

Genetics

- Approximately 90% of cases are the result of chromosomal nondisjunction (failure to segregate during meiosis) in the maternal DNA.
- <5% of cases are the result of paternal nondisjunction.
- 3–4% of cases are the result of translocations; mostly chromosomes 21 and 14 [t(14q21q)]; rarely between 21 and 13 or 15; 75% of translocations are sporadic de novo events; the others result from balanced translocations in one parent.
- Of live births, 1–2% are mosaic (nondisjunction occurs after conception; 2 cell lines are present); generally less severely affected

DIAGNOSIS

HISTORY

- Check for previous history of infant with Down syndrome in the family.
- Growth and developmental status
- Feeding problems
- Snoring, signs of sleep apnea (e.g., restless sleep)
- Stool habits
- Hearing concerns

PHYSICAL EXAM

The phenotype is variable from person to person.

- General
 - Short stature
 - Hypotonia (80–100%), with an open mouth and a protruding tongue
 - Midface hypoplasia
- Head
 - Brachycephaly with a flattened occiput
 - Microcephaly
 - False fontanelle (95%)
 - Late closure of fontanelles
- Eyes

- Upslanting palpebral fissures (98%)
- Inner epicanthal folds
- Brushfield spots (speckling of the iris)
- Fine lens opacities on slit-lamp examination
- Cataracts, refractive error, strabismus, and nystagmus
- Ears
 - Small, prominent, low set; overfolding of upper helix and small canals
- Nose: small (85%); flat nasal bridge
- Tongue
 - Relative but not true macroglossia (tongue mass is normal)
 - Fissuring of tongue
- Mouth: high-arched or abnormal palate
- Teeth
 - Missing (50%), small, hypoplastic
 - Irregular placement
- Neck
 - In infancy, excess skin at the nape
 - Short appearance
 - Occasionally webbed
- Heart: murmur, arrhythmia, cyanosis
- Abdomen
 - In neonate, distention may be present owing to obstruction or atresia.
 - Diastasis recti
- Genitals
 - In adolescents, straight pubic hair
 - In males, small penis, cryptorchidism
- Extremities
 - Broad hands, with short metacarpals and phalanges
 - 5th finger with hypoplasia of the midphalanx (60%) and clinodactyly (50%)
 - Simian crease (single transverse palmar crease) in ~50%. A newborn with a simian crease has a 1 in 60 chance of having Down syndrome.

- Wide gap between the 1st and 2nd toes (96%)
- Syndactyly of 2nd and 3rd toes
- Hyperflexibility of joints
- Skin
 - Cutis marmorata (43%)
 - In older children, hyperkeratotic dry skin (75%)
 - Fine, soft, sparse hair

DIAGNOSTIC TESTS & INTERPRETATION

Prenatal

- 2nd-trimester prenatal quad screen test (alpha-fetoprotein [AFP], unconjugated estriol, human chorionic gonadotropin [hCG], and inhibin A):
 - Performed at 15–18 weeks
 - These serum markers together can detect 67–76% of pregnancies affected by trisomy 21, with a false-positive rate of ~5%.
 - A positive test is an indication for karyotyping with amniocentesis.
- 1st-trimester maternal serum screening (pregnancy-associated plasma protein A and free β -hCG)
- When 1st- and 2nd-trimester tests are combined, there is a detection rate of 95%.
- New 2nd-trimester noninvasive prenatal screening (NIPS) tests are available to assess fetal DNA in the maternal circulation as a supplement to other tests.

Postnatal

- Chromosomal karyotype on cultured lymphocytes from peripheral blood: may be performed postnatally for confirmation if there is a clinical suspicion of Down syndrome
- Complete blood count (CBC)
 - In the newborn period to check for polycythemia and transient myeloproliferative disorder; repeat test in adolescence.
- Down syndrome patients may have an increased mean corpuscular volume (MCV), making the diagnosis of iron deficiency anemia difficult.
- Thyroid function tests: to rule out hypothyroidism or hyperthyroidism

Imaging

- 1st-trimester ultrasound measurement of nuchal translucency: performed in the 1st trimester along with maternal serum screening
- Fetal ultrasound
 - May show polyhydramnios if bowel obstruction is present
 - A thickened nuchal fold, an absent nasal bone in the 1st trimester, and echogenic intracardiac foci have been associated with an increased risk for Down syndrome.
- Echocardiography and chest radiography: done in the 1st month of life to rule out cardiac disease
- When symptoms suggestive of atlantoaxial instability (e.g., neck and/or radicular pain, weakness, change in tone, difficulties walking, or changes in bowel and bladder function) are present, lateral cervical spine radiographs in flexion, neutral, and extension: to rule out atlantoaxial instability, defined as >5-mm space between atlas and odontoid process of the axis. Important measures include the following:
 - Atlantodens interval (ADI; normal <4.5 mm): the distance between the posterior surface of the anterior arch of C1 and the anterior surface of the dens
 - Neural canal width (NCW; normal ≥ 14 mm): the distance between the posterior surface of the dens and the anterior surface of the posterior arch of C1
 - Distance of subluxation at the occipitoatlantal joint: normally ≥ 7 mm

Diagnostic Procedures/Other

- Prenatal karyotyping via amniocentesis (16–18 weeks' gestation) or chorionic villus sampling (9–11 weeks' gestation)
 - Performed for any woman who presents with a positive triple or quad screen
 - May be offered if prenatal ultrasound reveals a finding associated with Down syndrome
 - Because this test fails to detect 10–15% of Down syndrome in older women, amniocentesis is typically offered to all women >35 years of age.

- Tissue sample other than blood (usually skin): to check for mosaicism

Follow-up Recommendations

- Genetic counseling and evaluation is recommended.
- Referral to organizations (e.g., Down Syndrome International), parent-to-parent support groups, and other community supports available to families of children with Down syndrome

Prognosis

- Life expectancy is mildly decreased, with many living into the 6th decade; median age of death is 49 years.
- Clinical signs of Alzheimer disease occur later in life, with reports as high as 51% in the 4th decade.
- As adults, most patients with Down syndrome can work in supported positions.

Complications

- Otitis media with effusion (50–70%)
- Sinusitis
- Tonsillar and adenoidal hypertrophy
- Obstructive airway disease with associated sleep apnea (50–79%), cor pulmonale
- Obstructive bowel disease (12%, newborn period)
- Constipation (owing to low tone and decreased gross motor mobility)
- Subluxation of the hips (secondary to ligamentous laxity)
- Atlantoaxial instability (10–30%; secondary to ligamentous laxity, which is most severe prior to age 10 years)

Patient Monitoring

- Annually: growth and development:
 - Current recommendations by the American Academy of Pediatrics (AAP) are to use standard growth charts for all children including those with Down syndrome because the previously used Down syndrome growth charts are no longer felt to represent the current body proportion.
 - Average age for acquiring developmental milestones differs from normal population.
 - Early intervention program for hypotonia and developmental delay

is recommended.

- Review need for physical, occupational, and speech therapy at each health maintenance visit.
- Discuss psychosocial and behavioral progress and concerns and screen for mental health disorders (e.g., autism, ADHD).
- Assessment of nutrition and activity for obesity prevention/counseling
- Evaluation/referrals for available family support including medical, financial, and social services and school transitions
- Injury and abuse prevention
- Cardiac: Early evaluation in newborn period, with follow-up until the presence or absence of disease is evident. Subacute bacterial endocarditis prophylaxis for patients with certain types of cardiac disease.
- Ophthalmologic
 - Early evaluation for cataracts and glaucoma
 - Visit to ophthalmologist by 6 months, annually until age 5 years, then every 2–3 years
- Ear, nose, and throat (ENT)/audiologic
 - Audiologic evaluation; if newborn evaluation was normal, repeat at 6 months of age in the first 3 years of life, then every other year.
- Obstructive sleep apnea
 - Review symptoms with family in first 6 months and screen for symptoms at each well child visit.
 - Refer all children for sleep study or polysomnography by 4 years of age and at any age if symptomatic.
- Orthopedic: Routine screening by x-ray for atlantoaxial instability in asymptomatic children is no longer routinely recommended by the AAP, although it is still required for participation in the following Special Olympics activities: butterfly stroke and diving starts in swimming, diving, pentathlon, high jump, equestrian sports, artistic gymnastics, soccer, alpine skiing, and any warm-up exercise placing undue stress on the head and neck.
- Endocrine: thyroid function tests in newborn period, ages 6 months and 12 months, then yearly
- Gastrointestinal: Screen for symptoms of celiac disease (i.e., diarrhea,

poor growth, failure to thrive, etc.), and if symptomatic, obtain tissue transglutaminase immunoglobulin A (IgA) level and quantitative IgA.

- For adolescents, discuss personal hygiene and issues related to reproductive health.

ALERT

- Use caution with endotracheal intubation if absence or presence of atlantoaxial instability is unknown in order to avoid spinal cord injury, which may be seen in rare cases.
- Hearing loss may be misinterpreted as a behavioral problem.
- Use care with atropine and pilocarpine for ophthalmologic evaluation because of possible cholinergic hypersensitivity.

CODES

ICD10

- Q90.9 Down syndrome, unspecified
- Q90.2 Trisomy 21, translocation
- Q90.1 Trisomy 21, mosaicism (mitotic nondisjunction)

PATIENT TEACHING

- Participation by individuals with Down syndrome who have atlantoaxial instability. See:
http://sports.specialolympics.org/specialo.org/special_/English/coach/co
- Down syndrome. See:
http://kidshealth.org/parent/medical/genetic/down_syndrome.html

FAQ

- Q: Why was Down syndrome referred to as mongolism in the past?
- A: There was a mistaken notion about a racial cause for this syndrome because of the facial appearance, which was thought to be similar to that of those of Mongoloid origin.
- Q: Do all children with Down syndrome have mental retardation?
- A: No. Although all persons with nonmosaic Down syndrome have some degree of cognitive disability, some have IQs >70 and are not considered to have mental retardation.
- Q: Can a normal cardiac examination rule out the presence of a cardiac anomaly?
- A: No. The AAP recommends that all patients with Down syndrome have a cardiology consultation within the 1st month of life. Timely surgery may be necessary to prevent serious complications.
- Q: Are patients with atlantoaxial instability symptomatic?
- A: No. Most are asymptomatic, but symptoms of cord compression may be seen in 1–2% of patients. Patients with neck and/or radicular pain, weakness, change in tone, difficulties walking, or changes in bowel and bladder function should undergo radiologic evaluation for atlantoaxial instability.

DROWNING

Mercedes M. Blackstone

BASICS

DESCRIPTION

- Drowning is defined as respiratory impairment from submersion in a liquid medium.
- The term “drowning” does not imply outcome; drowning can be fatal or nonfatal.
- Historically “near drowning,” or submersion injury, was defined as survival, at least temporarily, after suffocation by submersion in water.
 - The World Congress on Drowning and the World Health Organization advocate abandoning confusing terms such as “near drowning,” “wet drowning,” and “dry drowning”; they suggest that the literature should only use the term “drowning.”

EPIDEMIOLOGY

- Drowning is second only to motor vehicle collisions as the most common cause of death from unintentional injury in childhood.
- For every drowning death, another 5 children present to emergency departments for nonfatal submersion events.
- Bimodal age distribution, with peak in children <5 years of age and again among adolescents 15–19 years of age
- Bathtub drowning is common in babies; child neglect or abuse should be considered.
- Adolescent submersion injuries usually involve substance abuse or risk-taking behavior.

RISK FACTORS

- Males, children <5 years of age, African Americans, and children of low socioeconomic status are at greatest risk.
- Other significant risk factors include the following:
 - Direct access to swimming pools
 - Poor swimming ability or overestimation of ability

- Use of alcohol and illicit drugs
- Inadequate adult supervision
- Children with seizure disorders or primary cardiac arrhythmias such as long QT syndrome

GENERAL PREVENTION

- Most drowning are preventable.
- Legislation to require adequate 4-sided isolation fencing and rescue equipment for public and residential pools
- Restriction of sale and consumption of alcohol in boating areas, pools, and beaches
- Life vests for children of all ages near bodies of water
- Parental education regarding adequate supervision during bathing and around swimming pools
- Cardiopulmonary resuscitation (CPR) courses for pool owners, parents, and older children

PATHOPHYSIOLOGY

- Drowning begins with a loss of the normal breathing pattern as panic ensues and subsequent apnea, laryngospasm, or aspiration occurs.
- Water aspirated into the trachea and lungs washes out surfactant and leads to atelectasis, intrapulmonary shunting, poor lung compliance, increased capillary permeability, and hypoxemia, ultimately resulting in acute respiratory distress syndrome (ARDS).
- Severe hypoxemia is the final common pathway and results in multisystem organ failure.
- Cerebral hypoxia results in cerebral edema and increased intracranial pressure and causes the majority of morbidity and mortality associated with drowning.

COMMONLY ASSOCIATED CONDITIONS

- Cervical spine injuries should be considered in older children who have experienced diving accidents but are otherwise relatively rare in drowning events.
- Signs of child abuse or neglect should be sought in young children.
- Adolescents may have associated toxic ingestions.

DIAGNOSIS

HISTORY

- Mechanism
 - History of diving or other high-impact injury
 - Intoxication
 - Seizure disorder
 - Cardiac arrhythmia
 - Child abuse
- Prognostic indicators; the following have been correlated with a poor prognosis and may be helpful to ask about:
 - Age <3 years
 - Length of submersion >5 minutes
 - Time to effective CPR >10 minutes
 - Lack of vital signs at the scene
 - Length of resuscitation >25 minutes
 - Warmer water: Submersion in cold water (<5°C [41°F]) may have a good prognosis despite submersion time >5 minutes.

PHYSICAL EXAM

- Vital signs with core temperature
- Drowning victims with unclear histories must be treated as trauma victims.
- Neurologic
 - Pupillary response, cranial nerve findings, Glasgow Coma Scale (GCS) score, gag reflex
 - Serial neurologic exams should be performed to assess neurologic outcome. Children with a GCS score <5 after resuscitation usually have a poor neurologic outcome.
- Respiratory
 - Lower airway findings (rales, tachypnea, wheezing, retractions, nasal flaring)
 - Drowning victims may have deteriorating pulmonary involvement despite an initially normal exam. Watch closely for signs of lower airway involvement.

- Circulation
 - Perfusion, strength of distal pulses, capillary refill, urine output, cardiac rhythm
- GI tract
 - Abdominal distention from swallowed water or ventilation
- Musculoskeletal
 - Neck injuries in high-impact drownings

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Arterial blood gases
 - To detect and facilitate treatment of metabolic acidosis in the child with respiratory distress or apnea
- Electrolytes
 - Not indicated in the seemingly well child; aspiration of huge amounts of water is required to generate electrolyte shifts.
- Blood glucose
 - An elevated level correlates with poor outcome for comatose submersion victims.
- Anticonvulsant levels for victims with seizure disorders
- Toxicology screening when ingestion suspected
- Children with severe submersion injuries are at risk of multiorgan system failure, and in these patients, end organ labs should be checked including coagulation studies.

Imaging

- A chest radiograph is indicated for children with signs of pulmonary involvement and after intubation.
 - Caution: Initial chest radiographs may be normal in the drowning victim.
- Cervical spine films are indicated for victims of high-impact events.
- Neuroimaging for cerebral anoxic injury

Diagnostic Procedures/Other

- ECG to document normal rhythm and evaluate for prolonged QT_C if indicated by history
- Serial pulse oximetry to detect early signs of pulmonary involvement

TREATMENT

MEDICATION

- Patients may experience bronchospasm and typically respond to conventional management with inhaled beta-agonists.
- Prophylactic antibiotics or steroids are not indicated.
- For patients who develop pneumonia, antimicrobial therapy should cover waterborne pathogens (e.g., *Pseudomonas*, *Aeromonas*).
- Seizures should be aggressively controlled with antiepileptics because they increase oxygen consumption.

ADDITIONAL TREATMENT

General Measures

- Good prehospital care and effective bystander CPR dramatically improve chances of neurologically intact survival.
- Attempts to remove water from the lungs such as abdominal thrusts or Heimlich maneuver delay care and are not recommended.
- Cervical spine immobilization can interfere with airway management and should only be performed when injury is suspected.
- Patients who are breathing spontaneously should be placed in the right lateral decubitus position to prevent aspiration.
- CPR in drowning victims should follow the traditional ABC approach rather than compression-only CPR because prompt rescue breathing increases the chance of survival.
- Even patients who respond well to bystander resuscitation need to be transported to an emergency department for further monitoring.
- Pulses may be difficult to appreciate as they can be weak and slow due to hypothermia; some common arrhythmias such as sinus bradycardia and atrial fibrillation need no immediate treatment.
- The hypothermic patient who is a warm water (>20°C [86°F]) drowning victim does not have a good prognosis or need vigorous rewarming.

INPATIENT CONSIDERATIONS

Initial Stabilization

- Airway

- Protect the cervical spine if indicated by history.
- Ensure a patent airway in the comatose victim or patient in cardiac arrest.
- Breathing
 - Supplemental oxygen via facemask with any compromise or desaturation following their submersion event
 - Intubate for apnea, airway protection, or inadequate oxygenation or ventilation
 - Treatment of bronchospasm
- Circulation
 - For the victim with cardiopulmonary arrest, the asystole protocol should be followed.
 - Because capillary leak may occur after an ischemic/anoxic episode, isotonic fluids (e.g., normal saline solution or Ringer lactate, 10-mL/kg aliquots) should be given for signs of intravascular volume depletion until normalized.
 - ECG monitoring should be provided with appropriate response to dysrhythmias, especially for the hypothermic, cold water drowning victim.
 - For severely hypothermic patients with a core temperature $<28^{\circ}\text{C}$ (82.4°F), aggressive rewarming is indicated. Electrical defibrillation and pharmacotherapy may not be successful.
- Disability
 - Maintenance of eucapnia and adequate oxygenation to prevent further hypoxemia
 - Elevate the head of the bed once cervical spine is cleared and consider mild hyperventilation for elevated intracranial pressure (ICP).
 - Other measures for reducing ICP have not proven effective, likely because the brain injury and swelling is secondary to hypoxic cell injury as opposed to a traumatic lesion.
- Exposure
 - The drowning victim should be dried and warmed.
 - Most thermometers do not register temperatures below 34°C (93.2°F) so a hypothermia thermometer may be necessary:

- For core temperatures 32°C (89.6°F) to 35°C (90.5°F), active external rewarming with heating blankets or radiant warmers
- For <32°C (89.6°F), active internal rewarming added (heated aerosolized oxygen and IV fluids, gastric and bladder lavage with warm saline)
- For severe hypothermia (<28°C [82.4°F]) and where available, peritoneal dialysis or hemodialysis, mediastinal irrigation, and cardiac bypass
- The cold water drowning victim with hypothermia must be rewarmed to a temperature >34°C (89.6°F) before CPR is terminated.
- Remember: The saying, “The patient is not dead until he or she is warm and dead” only applies to drownings in very cold water.

Admission Criteria

- Severely ill children require admission to the intensive care unit.
- Children who were apneic, cyanotic, or pulseless at the scene should be admitted for close observation even if they appear well.
- Patients who are at all symptomatic should be admitted to a monitored setting.
- A subset of asymptomatic children may be discharged from the emergency department after being monitored for 6–8 hours.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Long-term follow-up of apparently neurologically intact survivors has shown mild coordination or gross motor deficiencies.
- Potential increased risk for chronic lung disease, depending on pulmonary involvement

Patient Monitoring

- Victims who appear well and had relatively minor event:
 - Monitor with pulse oximetry for progressive respiratory distress.
 - If asymptomatic at 6–8 hours postimmersion, can be discharged
- Victims with significant neurologic injury: Key is to prevent secondary

injury.

- Maintain euvolemia and euglycemia.

PROGNOSIS

- Most children (about 75%) recover with intact neurologic survival.
- Duration and severity of initial hypoxic insult are most important determinants of brain injury and death.
- See prognostic factors in “[History](#)” section. Additional indicators of poor prognosis:
 - Coma on arrival
 - Needing CPR in the emergency department
 - Initial arterial blood pH <7.1
- Children with warm water submersion time >4 minutes who do not receive CPR at the scene and who have absent vital signs or a GCS score <5 in the emergency department usually have a poor prognosis.
- Victims who have prolonged submersions in very cold water (<5°C [41°F]) may have a good prognosis because of core cooling with a concomitant decrease in metabolic rate while the brain is still being perfused.
- A good prognostic indicator is continuing improvement in the neurologic examination over the first several hours.

COMPLICATIONS

- Pneumonia
- Pneumomediastinum or pneumothorax in the patient undergoing ventilation therapy
- Brain injury secondary to hypoxia
- Pulmonary injury with intrapulmonary shunting secondary to damage of the alveoli
- ARDS
- Metabolic acidosis secondary to hypoxemia
- Ischemic injury to organs such as liver, kidneys, and intestines
- Disseminated intravascular coagulation
- Hypothermia in cold water drowning

CODES

ICD10

T75.1XXA Unsp effects of drowning and nonfatal submersion, init

FAQ

- Q: Should the drowning victim who arrives at the hospital with cardiopulmonary arrest be resuscitated?
- A: Yes. A brief (10–15 minutes) attempt at resuscitation is indicated

until circumstances of the drowning and core temperature are known. Warm water drowning victims who require CPR in the emergency department may rarely (0–25%) have good neurologic recovery, but these patients usually respond quickly (<15 minutes) to therapy.

- Q: Is artificial surfactant useful in drowning victims?
- A: Surfactant has not been found to be beneficial for acute lung injury secondary to drowning. Further investigation is needed before it can be recommended for clinical use.

DYSFUNCTIONAL ELIMINATION SYNDROME

Kara N. Saperston • Laurence Baskin

BASICS

DESCRIPTION

- Dysfunctional elimination syndrome (DES) is seen in children with bladder and bowel dysfunction in the setting of normal neurologic findings.
- We define dysfunctional voiding as tightening the pelvic floor muscles before completely emptying the bladder, which may leave a large amount of urine in the bladder.
 - DES also encompasses the underactive (“flaccid”) bladder, which is seen in children who postpone voiding and only empty a few times a day.
 - Constipation has a major role to play in affecting the bladder’s ability to store urine and also affects the bladder’s ability to empty completely and in a timely fashion.
- Patients with DES may also experience daytime and/or nighttime incontinence.

EPIDEMIOLOGY

- 15% of 6-year-olds have abnormal voiding patterns. Children with DES often have
 - Abnormal renal ultrasounds
 - Higher rates of urinary tract infections (UTIs)
 - A decreased ability to resolve vesicoureteral reflux (VUR)
- 89% of children who are treated for their constipation completely resolve their daytime urinary incontinence, and 63% resolve their nighttime incontinence.

RISK FACTORS

- Recurrent UTIs
- Constipation

PATHOPHYSIOLOGY

- A child who is holding his or her stool and not having regular daily bowel movements has increased stool in the rectal vault.
- As stool builds up in the rectal vault (constipation), it begins to push on the bladder. This process causes decreased bladder filling.
- In addition, the rectal vault shares sensory input in the sacral spinal cord with the bladder, and the full rectal vault can be sensed as a full bladder, triggering bladder spasms and leakage and/or incomplete emptying of the bladder.
- As a child struggles to stay dry in the face of bladder spasms, he or she overcontracts the external sphincter of the bladder, has a hard time relaxing the external sphincter during voiding, and develops increased pressure during voiding. This increased pressure can be transmitted to the kidneys.

DIAGNOSIS

HISTORY

- A child will present after toilet training with symptoms of daytime and/or nighttime incontinence.
- In addition, he or she may have a history of recurrent UTIs or VUR.
- Bowel dysfunction may present as encopresis, constipation, or as fecal impaction.

PHYSICAL EXAM

- Most commonly, the exam will be normal.
- Abdomen: palpable bladder or stool in the colon
- Evaluate the spine for skin discoloration, dimples, or hair patches to rule out occult spinal dysraphism.
- Evaluate female genitalia and rule out labial adhesions that can trap urine and cause incontinence.
- Consider possible ectopic ureter if there is vaginal pooling of urine.
- Evaluate male genitalia and rule out prior hypospadias repair or severe phimosis in which urine trapping can occur.
- Rectal exam can reveal fecal impaction.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Urinalysis to rule out bacteriuria or glucosuria
- First morning urine osmolality to assess renal concentrating ability in nocturnal enuresis

Imaging

- Radiograph of kidneys, ureters, and bladder (KUB): constipation, normal spine
- Renal ultrasound: pre- and postvoid images to evaluate the bladder and kidneys

Diagnostic Procedures/Other

- Voiding/drinking
 - Diary is a tool used to define the nature of the incontinence.
- Voiding cystourethrogram (VCUG)
 - Used to evaluate for VUR and to look at the urethra and bladder neck during voiding
- Urodynamic studies
 - Tools used to define bladder function if there is a poor response to initial management
 - Uroflow is used to evaluate bladder outflow.
 - Cystometry and perineal EMG studies give information about bladder function during filling and voiding.

DIFFERENTIAL DIAGNOSIS

- Ectopic ureter to the vagina
- Spinal cord abnormalities (tethered cord)
- Brain tumors

TREATMENT

BEHAVIOR MODIFICATION

- Educate proper voiding mechanics.
- Timed voiding every 2 hours; may use a watch with a repeating alarm
- Correct sitting and standing positions during voiding
- Modify drinking and voiding habits based on diaries to attain frequent

voiding and regular stooling.

- Encourage plenty of water intake; fiber for management of constipation
- Time set aside to attempt regular morning bowel movements

MEDICATION

- Bowel management
 - Goal: full clean out
 - Clean out usually lasts 3 days.
 - Use polyethylene glycol 3350 (MiraLax)/ lactulose and enemas and/or mineral oil.
 - If severe, can use KUB to confirm clean out is complete
- Daily management
 - Goal: 1–2 soft bowel movements daily
 - Polyethylene glycol 3350 (MiraLax)/lactulose daily dosing and/or mineral oil help for daily maintenance.
- Antimuscarinics
 - Are used for overactive bladders
 - Work by reducing the frequency and intensity of the bladder contraction
 - Can be supplied in short-acting and long-acting formulas or transdermally

ALERT

Make sure the patient has truly had a good bowel clean out and is focusing first on 1–2 daily soft bowel movements before adding medications to treat the bladder symptoms.

ADDITIONAL THERAPIES

- Biofeedback
- Acupuncture
- Neuromodulation

GENERAL MEASURES

- When a provider is treating a child with bladder and bowel dysfunction, it is imperative that the focus begins with daytime management first, specifically focusing on soft daily bowel movements and timed voiding.

- The nighttime wetting will not improve until the daytime wetting and the constipation have been properly managed.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Children with recurrent febrile UTIs should be referred to pediatric urology.
- Children with abnormal renal ultrasound should be referred to pediatric urology.
- Children who don't resolve their incontinence after initial management of the bowel dysfunction should be referred to pediatric urology.

PROGNOSIS

- 80% of children are able to resolve their symptoms, with attention given to their bowel function and timed voiding.
- Because this treatment predominantly involves making behavioral changes, this process does not occur quickly. Time and patience are required by both the parents and the children.

- Loening-Bauke V. Urinary incontinence and urinary tract infection and their resolution with treatment of chronic constipation of childhood. *Pediatrics*. 1997;100(2, Pt 1):228–232.

CODES

ICD10

- R32 Unspecified urinary incontinence
- K59.00 Constipation, unspecified
- R15.9 Full incontinence of feces

FAQ

- Q: Should children with DES have urodynamic evaluation?
- A: Rarely. A patient should undergo standard therapy with timed voiding and treatment of constipation as the 1st-line therapy. If that fails, then a referral to pediatric urology is appropriate, and the need for further testing will be assessed.

DYSFUNCTIONAL UTERINE BLEEDING

Leonard J. Levine • Jonathan R. Pletcher

BASICS

DESCRIPTION

- Bleeding beyond the range of normal menses, with “normal” defined as duration of 2–8 days, occurring every 21–40 days, with blood loss of 20–80 mL/cycle
- May vary in presentation from heavy, long menses followed by long periods of amenorrhea to short, heavy menses occurring every 1–2 weeks
- In teens, dysfunctional uterine bleeding (DUB) most commonly results from anovulatory cycles, which are secondary to an immature hypothalamic–pituitary–ovarian axis.

EPIDEMIOLOGY

- DUB commonly occurs within the first 2 years of menarche when >50% of cycles are anovulatory.
- Later age at menarche associated with longer duration of anovulation
- Most females who experience anovulatory cycles do not develop DUB.

RISK FACTORS

Genetics

Patients with disorders, such as blood dyscrasias and polycystic ovary syndrome (PCOS), usually have familial histories of similar disorders.

PATHOPHYSIOLOGY

- Anovulation (failure to ovulate) results in corpus luteum absence.
- Without the secretory effect of progesterone from the corpus luteum, endometrial proliferation continues because of unopposed estrogen.
- The thickened endometrium eventually outgrows support from the basal endometrium, resulting in sloughing of the highest endometrial levels. Alternatively, cyclic estrogen withdrawal may occur, which will lead to sloughing of the endometrium in the absence of progesterone.

- As subsequent levels of endometrium are shed, bleeding increases. Profuse bleeding may result when the basal endometrium is exposed.

DIAGNOSIS

HISTORY

- Abnormal bleeding
 - Assess the amount of bleeding, and confirm if it is vaginal bleeding.
 - Important to know when bleeding began and some estimate of blood loss to know if the patient is at risk for anemia or hemodynamic instability
- The pattern of DUB in relation to the menstrual cycle can help guide the diagnostic workup.
 - Normal cyclic intervals with increased bleeding during each cycle may suggest a bleeding disorder.
 - Normal intervals with bleeding between cycles may suggest infection or foreign body.
- Abnormal intervals with no cycle regularity may suggest anovulatory cycles or endocrinopathy or be a side effect of hormonal contraception.
 - Increased time lapse between menarche and onset of DUB lessens the likelihood of anovulatory cycles.
 - Teens with chronic diseases and active health problems may have prolonged anovulatory cycles.
- Easy bruisability, epistaxis, and/or bleeding gums may be suggestive of a bleeding disorder.
- A family history of thyroid disease, bleeding disorder, PCOS, or DUB will help guide the laboratory workup.
- Personal and immediate family history of thromboembolism or known familial risk factors
- Ask about sexual activity and abuse in a safe, confidential setting.

PHYSICAL EXAM

- Often normal in patients with DUB
- Assess vital signs, including orthostatic BPs, for signs of cardiac instability resulting from severe blood loss.

- Skin or mucosal pallor, elevated heart rate, or flow murmur may be indicative of anemic state.
- Assess sexual maturity rating (SMR, or Tanner stage). Menarche usually does not occur before SMR 3, so bleeding before this stage suggests a nonmenstrual source of bleeding.
- Look for signs of androgen excess (e.g., hirsutism, acne), which may be reflective of disrupted ovulatory function.
- Bitemporal hemianopsia is suggestive of a pituitary adenoma leading to hyperprolactinemia.
 - Hyperprolactinemia can result in anovulation.
 - Only 1/3 of adolescents with hyperprolactinemia will experience galactorrhea.
- Assess for evidence of thyroid disease, hematologic disorder (e.g., bruising, petechiae), or systemic disease (e.g., poor nutritional status).
- Speculum-assisted pelvic examination may help determine source of bleeding. Bimanual examination is helpful in assessing ovarian or uterine masses, cervical motion or adnexal tenderness, and uterine sizing.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Obtain urine or serum human chorionic gonadotropin (β -hCG), regardless of sexual history. Urine hCG testing can reliably detect pregnancy as early as 2 weeks postconception; however, it may be positive for up to 2 weeks following a miscarriage or abortion.
- CBC: Degree of anemia guides treatment plan. Assess for thrombocytopenia. In the setting of acute blood loss, a normal hemoglobin may be falsely reassuring. It is wise to recheck hemoglobin after IV hydration, as decreases may be dramatic.
- For Chlamydia trachomatis and Neisseria gonorrhoeae, obtain cervical cultures or use nucleic acid amplification tests (NAATs) (e.g., PCR or LCR) on urine, vaginal, or cervical swabs. Be careful to check with laboratory or NAAT manufacturers' information regarding reliability with blood in sample and based on collection site.
- Wet mount or vaginal swab may be unreliable but should be attempted for presence of WBCs and Trichomonas. In some labs, Trichomonas

vaginalis antigen tests may be available.

- Consider prolactin level and thyroid function tests (TSH, T₄):
Hyperprolactinemia may have several causes, including pituitary microadenoma, and result in amenorrhea or DUB.
- Prothrombin and partial thromboplastin time, von Willebrand factor: to assess for hematologic causes of bleeding
- Androgen levels, including testosterone (total and free), dehydroepiandrosterone sulfate (DHEAS), androstenedione: Abnormal levels are supportive of PCOS or other hyperandrogenic state.

Imaging

- Pelvic ultrasound
 - Indicated when pregnancy is suspected (ectopic or intrauterine)
 - Consider when a pelvic mass is felt, uterine anomaly is being considered, or bimanual examination cannot be completed
- MRI of the pelvis: Indicated for patients with a suspected pelvic mass when ultrasonography does not clearly define the anatomy

ALERT

Pitfalls

- Neglecting to perform pregnancy testing in an adolescent who denies sexual activity
- Neglecting to reassess hemoglobin concentration after volume expansion

DIFFERENTIAL DIAGNOSIS

Although most cases of abnormal uterine bleeding in adolescents can be attributed to anovulatory cycles, it is important to rule out underlying and alternate causes of irregular or heavy bleeding.

- Pregnancy: should be considered and ruled out in every patient, regardless of patient's reported sexual history
 - Ectopic pregnancy
 - Threatened abortion, incomplete abortion
 - Placenta previa
 - Hydatidiform mole
- Infection
 - Vaginitis (e.g., trichomoniasis)

- Cervicitis or endometritis (e.g., gonorrhea or chlamydia)
- Pelvic inflammatory disease
- Hematologic conditions
 - Thrombocytopenia (e.g., immune thrombocytopenic purpura [ITP], leukemia)
 - Platelet dysfunction
 - Coagulation defect (e.g., von Willebrand disease)
- Endocrinologic disorders
 - Hyper- or hypothyroidism
 - Hyperprolactinemia
 - PCOS
 - Adrenal disorders
- Trauma: laceration to vagina or cervix
- Foreign body: usually associated with strong, foul odor
- Medications
 - Direct effect on hemostasis (e.g., Coumadin, chemotherapeutic agents)
 - Hormonal effects (e.g., oral contraceptives, Depo-Provera, other exogenous steroid hormones)
- Systemic disease
 - Disruption of hypothalamic–pituitary–ovarian axis
 - Other examples include systemic lupus erythematosus and chronic renal failure.
- Primary gynecologic disorders
 - Endometriosis
 - Uterine polyps, submucosal myomas
 - Hemangioma, arteriovenous malformation

TREATMENT

GENERAL MEASURES

- For mild DUB (inconvenient, unpredictable bleeding, and the patient has a normal hemoglobin in setting of hemodynamic stability)
 - Reassurance until ovulatory cycles resume. Encourage maintenance of a menstrual calendar, with follow-up in 3–6 months.

- Iron supplementation
- If anxiety is unresponsive to reassurance, hormonal therapy with a daily combined oral contraceptive pill (OCP), 1 tablet daily, should be considered to regulate menstrual cycle; if estrogen is contraindicated, may use progesterone-only pill, medroxyprogesterone acetate 5–10 mg/24 h PO for 10–14 days every month
- For mild to moderate DUB, a progestin-containing intrauterine device may be indicated.
- For moderate DUB (irregular, prolonged, heavy bleeding with a hemoglobin >10 g/dL)
 - Hormonal therapy, as described previously; may start OCP containing 35 mcg of ethinyl estradiol twice a day until bleeding stops, then taper to once a day
 - Menstrual calendar with follow-up every 1–3 months
- For severe DUB (i.e., heavy, prolonged bleeding with a hemoglobin <10 g/dL), treatment depends on the presence of active bleeding.
 - If no active bleeding, hemodynamically stable patients can be started on daily OCPs and iron supplementation, with follow-up in 1–2 months.
 - In the presence of active bleeding: Hormonal therapy using combined OCP containing higher dose of estrogen (50 mcg ethinyl estradiol)—1 pill q.i.d. until bleeding stops, followed by pill taper (q.i.d. for 4 days, t.i.d. for 3 days, b.i.d. for 2 weeks, then 1 pill daily); switch to lower dose pill (30–35 mcg) after taper is complete.
 - Hospitalization of patient during treatment if with severe anemia (hemoglobin <7 g/dL), if hemodynamically unstable, or with compliance concerns; blood transfusion as necessary
 - If patient is unstable or unable to tolerate oral pill regimen, can give IV conjugated estrogen q4h for 24 hours to stop bleeding. Add PO or IM progesterone as soon as possible.
 - Iron replacement
 - Dilation and curettage rarely necessary; may be needed if hormonal therapy fails
- Possible side effects

- Estrogen, given in high doses, will cause nausea and/or vomiting. An appropriate antiemetic should be used for prophylaxis against these symptoms.
- High-dose estrogen may have vascular side effects and should be used with caution in patients particularly at risk for vascular events (e.g., patients with a history of lupus, stroke, or thrombotic phenomena and those who smoke cigarettes). In these cases, consult a gynecologist or adolescent medicine specialist for an alternative progesterone-only therapy.

ALERT

Pitfalls

- Neglecting to provide both estrogen and progesterone in a timely fashion
- Neglecting to adequately assess or mediate risk for thromboembolic event related to estrogen therapy
- Neglecting to consider a retained foreign body (e.g., tampon)

INPATIENT CONSIDERATIONS

Initial Stabilization

If DUB is attributed to anovulatory cycles, or if a complete workup fails to yield a diagnosis, treatment is guided by the severity of DUB and the presence of active bleeding.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

When to expect improvement

- Bleeding usually tapers after the first few doses of hormone therapy.
- After 6–12 months, if patient does not wish to remain on OCPs, a trial off medication might reveal normal ovulatory cycles.
- Ongoing follow-up with an adolescent medicine or adolescent gynecologist may be warranted.

PROGNOSIS

DUB persists for 2 years in 60% of patients, 4 years in 50%, and up to 10 years in 30%.

COMPLICATIONS

Mild to severe anemia resulting from blood loss

- N92.3 Ovulation bleeding
- N93.9 Abnormal uterine and vaginal bleeding, unspecified

FAQ

- Q: If most girls have anovulatory cycles, why do only some present with DUB?
- A: Most girls do have irregular menstrual cycles during the first 2 years after menarche. However, in most, the negative-feedback system of estrogen leads to cyclic endometrial shedding in an anovulatory pattern.
- Q: If DUB from anovulatory cycles is caused by lack of progesterone, why does the initial treatment of severe DUB with active bleeding involve large doses of estrogen?
- A: Estrogen has procoagulation effects that promote hemostasis (e.g.,

effects on platelet aggregation and levels of fibrinogen and clotting factors). In addition, severe DUB may lead to an exposed endometrial base that bleeds profusely; for progesterone to exhibit its secretory effects, the endometrium in that area must be restored by estrogen.

- Q: When hormonal therapy fails, and the basal endometrium continues to bleed, how does a dilation and curettage act as the final treatment?
- A: The curettage removes any remaining bleeding vessels and stimulates local prostaglandins to create a uterine contracture that inhibits bleeding. This procedure is rarely needed in adolescent patients, as they usually respond to hormonal therapy.

DYSMENORRHEA

Zeev Harel

BASICS

DESCRIPTION

Bothersome menses, usually presenting as cramping pain in lower abdomen or back

- Primary dysmenorrhea—in absence of any pelvic abnormalities
- Secondary dysmenorrhea—due to pelvic abnormalities, most commonly endometriosis or reproductive tract anomalies

EPIDEMIOLOGY

- Primary dysmenorrhea
 - Typically begins in adolescence; prevalent in mid- to late adolescence when menstrual cycles become ovulatory
 - Less common in the first 2–3 years following menarche when cycles are anovulatory
- Secondary dysmenorrhea is more common later in adolescence and in young adults; it has been estimated that 15% of young adult women suffer from chronic pelvic pain, with up to 97% of these women having endometriosis.

Prevalence

- Very common gynecologic complaint that affects up to 90% of adolescents
- 15% of adolescents report that the pain is “severe,” limiting their daily activities.
- Many adolescents with dysmenorrhea either do not seek medical attention or are undertreated.

RISK FACTORS

- Early menarche
- Increased duration and amount of menstrual flow
- Nulliparity
- Cigarette smoking

- Low fish consumption
- Family history of dysmenorrhea

Genetics

- Dysmenorrhea is more common in patients with a positive family history.
- Particularly, there is a hereditary predisposition to endometriosis; mode of inheritance is polygenic, multifactorial, with expression related to interaction with environmental factors.

PATHOPHYSIOLOGY

- Ovulation leads to increased progesterone release in the second half of the menstrual cycle. With the drop in progesterone late in the menstrual cycle, arachidonic acid and other omega-6 fatty acids are released, triggering an inflammatory response cascade involving prostaglandins (PGs) and leukotrienes (LTs).
- Uterine PGs and LTs cause myometrial contractions and endometrial artery vasoconstriction, resulting in uterine ischemia and in ensuing pain.
 - $\text{PGF}_{2\alpha}$ is thought to stimulate the myometrium and cause vasoconstriction.
 - Severity of dysmenorrhea is directly proportional to endometrial $\text{PGF}_{2\alpha}$ concentrations.
- Vasopressin, also elevated among women with dysmenorrhea, may play a secondary role by potentiating uterine contractions and ischemic pain.
- PGs and LTs can affect other body systems/organs, leading to dysmenorrhea-associated symptoms such as nausea/vomiting, diarrhea, and headaches.
- In endometriosis lesions, there is an inappropriate local aromatase activity, leading to a local rise in estrogen, which induces transcription of cyclooxygenase (COX)-2 and synthesis of PGE_2 . Aberrant expression of cytokines also mediates inflammation/pain.
- The distinct possibility of a müllerian anomaly must also be considered as a cause for secondary dysmenorrhea.

DIAGNOSIS

- Primary dysmenorrhea
 - Painful, often spasmodic cramps of varying severity in the lower abdomen or back, starting hours to a few days prior to menses and lasting up to 2–3 days after the start of menses
 - Pain is strongest in intensity initially, waning by the end of menses. Referred pain to lower back or thighs may occur.
- Secondary dysmenorrhea
 - More likely to present with both cyclic and acyclic pain (chronic pelvic pain), metrorrhagia, and dyspareunia

HISTORY

- Given the high prevalence, screen all adolescent females for dysmenorrhea.
- Pain
 - Ask about quality and intensity of pain (use pain scales); constant or intermittent occurrence; location; onset, timing, and duration; aggravating or alleviating factors; extent to which the pain limits activities (work, school, sports, social).
- Menstrual history
 - Age at menarche: Dysmenorrhea is more common in girls with earlier menarche.
 - Menstrual flow: Dysmenorrhea is more common in women with heavy/long menstrual flow.
 - Last menstrual period (and previous one, if known)
 - Cycle regularity
- Sexual history
 - Parity, current sexual activity, contraception, and history of sexually transmitted infections (STIs) or pelvic inflammatory disease (PID). Adhesions may cause painful menses.
- Menstruation-associated symptoms: nausea, vomiting, diarrhea, headache, irritability, fatigue, breast tenderness, dizziness, bloating, and acne exacerbation
- History of sexual, physical, or emotional abuse

- Family history of gynecologic (GYN) diseases, including endometriosis, GYN or breast cancer, and complications with oral contraceptive pills (OCPs) including deep vein thrombosis (DVT), stroke, or myocardial infarction
- Medications: response to analgesic medications including name, dose, and perceived effectiveness
- Diet: Higher intake of omega-6 polyunsaturated fatty acids correlates with increased dysmenorrhea symptoms.

ALERT

- The adolescent health care provider should screen for menstrual symptoms at every encounter with the adolescent female.
- Menstrual pain that started at menarche or immediately after menarche is unlikely to be primary dysmenorrhea, as most girls are still having anovulatory cycles.
- Cigarette smoking may increase duration of dysmenorrhea.
- Consider a workup of endometriosis for hard to manage dysmenorrhea.

PHYSICAL EXAM

- Abdominal exam
 - Lower abdomen/suprapubic tenderness
 - Enlarged uterus can be palpated in vaginal outlet obstruction.
- Inspection of external genitalia: A cotton-tipped swab can be inserted into the vagina to evaluate for the presence of a transverse vaginal septum or vaginal agenesis.
- Pelvic exam
 - Defer in younger girls with mild, classic symptoms and normal external genitalia who have never been sexually active.
 - Perform in girls with history suggesting secondary dysmenorrhea, particularly if the patient failed treatment with nonsteroidal anti-inflammatory drugs (NSAIDs).

DIAGNOSTIC TESTS & INTERPRETATION

- Lab studies are generally not warranted.
- Consider testing for pregnancy, STIs, and PID as indicated by history and physical exam.

Imaging

- Consider pelvic ultrasound (US) for patients who fail a trial of NSAIDs.
 - US can rule out genital tract abnormalities and ovarian pathologies.
 - Pelvic US or pelvic magnetic resonance imaging (MRI) may be indicated, particularly to exclude obstructive anomalies.
- Although US and MRI can detect ovarian, vaginal, and bladder endometriosis and deeply infiltrative lesions, there are no good imaging modalities to detect intraperitoneal endometriosis lesions.

Diagnostic Procedures/Other

Consider a diagnostic laparoscopy with resection/ablation of lesions if indicated in patients with dysmenorrhea refractory to treatments with NSAIDs and OCPs, particularly if they have a 1st-degree relative with endometriosis.

DIFFERENTIAL DIAGNOSIS

Primary dysmenorrhea is a diagnosis of exclusion; secondary dysmenorrhea should be ruled out based on history, physical exam, response to initial treatment, and imaging if warranted.

- Causes of secondary dysmenorrhea
 - Endometriosis, congenital vaginal or uterine anomalies, adenomyosis, ectopic pregnancy, ovarian cysts or tumors, pelvic adhesions, PID, uterine adhesions, fibroids, or polyps
- Other diagnoses to rule out:
 - Gastrointestinal: constipation, diverticulitis, inflammatory bowel disease, irritable bowel syndrome
 - Urologic: interstitial cystitis, kidney stones, urinary tract infection
 - Neurologic: fibromyalgia, herniated disk, lower back pain

TREATMENT

MEDICATION

First Line

- NSAIDs
 - Conventional PG synthetase (COX) inhibitors

- If a patient fails to respond to the first choice at a therapeutic level, try a different NSAID.
- A COX-2 inhibitor should be considered in patients with prior history of peptic ulcer or gastrointestinal bleeding.
- 90% of patients have relief with proper dosing.
- Most effective when used on a regular basis for the first 2–3 days of menses
- If possible, start 1 day prior or at the onset of menses.
- Choices
 - Ibuprofen: 800 mg initially, followed by 400–800 mg PO q8h as needed
 - Naproxen sodium: 440–550 mg initially, followed by 220–550 mg PO q12h as needed
 - Mefenamic acid: 500 mg PO initially, followed by 250 mg PO q6h as needed
 - Celecoxib: 400 mg initially, followed by 200 mg q12h as needed (COX-2 inhibitor approved for girls ≥ 18 years)
- Side effects of conventional NSAIDs
 - Black box warnings: increased risk of adverse cardiovascular events, including myocardial infarction, stroke, and new-onset or worsening of preexisting hypertension; increased risk of gastrointestinal irritation, ulceration, bleeding, and perforation

Second Line

- OCPs
 - OCPs suppress ovulation and decrease uterine PG secretion following reduction in progesterone levels.
 - Good choice for patients who fail NSAIDs as monotherapy, desire pregnancy prevention, or who have acne
 - Patients may need 3 months to see improvement.
 - Extended cycling OCPs: can prescribe formulation for a 91-day cycle (e.g., Seasonale, Seasonique) or use multiple OCP packs to achieve same effect
 - Side effects: nausea, vomiting, breast tenderness, breakthrough menstrual bleeding, headaches from the estrogen; rare: DVT, stroke, myocardial infarction

- Long-acting hormonal contraceptives
 - Long-acting combined estrogen and progestin hormonal contraceptives such as the transdermal patch and the vaginal ring as well as long-acting progestin-only hormonal contraceptives such as the injectable depot-medroxyprogesterone acetate, etonorgestrel subdermal implant, and the levonorgestrel-releasing intrauterine system can also alleviate dysmenorrhea symptoms.
- Secondary dysmenorrhea is treated by addressing the underlying cause. Extended OCP regimen is the first line of treatment for endometriosis. Medical management in patients refractory to noncyclic OCP may proceed to treatment with a gonadotropin-releasing hormone (GnRH) agonist.

ISSUES FOR REFERRAL

Consider referral to adolescent gynecologist for possible laparoscopy or management of endometriosis.

COMPLEMENTARY & ALTERNATIVE THERAPIES

- Supplementation with vitamin B₁, magnesium, or omega-3 fatty acids have been shown to alleviate dysmenorrhea symptoms.
- Transcutaneous electrical nerve stimulation (TENS): Electrodes on the skin stimulate nerves at different current frequencies and intensities. Better results are reported with high frequency than with low frequency.
- Exercise may help to reduce symptoms of dysmenorrhea (due to release of endorphins).
- Acupuncture, yoga, and heat therapy may also reduce dysmenorrhea symptoms.

SURGERY/OTHER PROCEDURES

Laparoscopic techniques for interruption of the uterosacral nerves may be used as treatment for primary dysmenorrhea when other modalities have failed.

- Laparoscopic uterine nerve ablation (LUNA) is effective for long-term (≥ 12 months) pain relief in primary dysmenorrhea.
- Laparoscopic presacral neurectomy is more effective than LUNA for pain relief at ≥ 6 months follow-up but has significant side effects

especially constipation; it should only be performed by pelvic laparoscopic surgeons with special training.

ALERT

- There are a number of over-the-counter medicines that are marketed for treating cramps in women. Only those formulations that contain NSAIDs are effective in treating dysmenorrhea.
- Start an adequate dose of pain medication at first awareness of approaching menses.
- Estrogen and progestin hormones are also used for treatment of dysmenorrhea and do not lead to adolescent sexual activity.

ONGOING CARE

DIET

Encourage patients to increase consumption of fish rich in omega-3 fatty acids.

PATIENT EDUCATION

- Stress to patients the importance of keeping a pain diary indicating days of menses, days of pain, pain ratings (0–10 scale), days of limited activities (school or work) due to pain, and associated symptoms.
- Web site for patient education materials
 - American College of Obstetricians and Gynecologists.
Dysmenorrhea.
<http://www.acog.org/~/media/For%20Patients/faq046.pdf?dmc=1&ts=20121119T1244369567>

PROGNOSIS

Improvement in dysmenorrhea symptoms may occur after childbirth.

COMPLICATIONS

Missed school or work, decreased academic performance, sports participation, and peer socialization

CODES

ICD10

- N94.6 Dysmenorrhea, unspecified
- N94.4 Primary dysmenorrhea
- N94.5 Secondary dysmenorrhea

FAQ

- Q: What percentage of patients report dysmenorrhea?
- A: Although dysmenorrhea affects up to 90% of adolescents, fewer than 15% will seek medical care. It is important to screen all adolescent women for dysmenorrhea. Barriers to seeking physician advice include fears of pelvic exam and lack of knowledge of effective treatments.
- Q: When to refer a patient with dysmenorrhea to laparoscopy?
- A: Although pelvic US and MRI can detect some endometriosis lesions, there are no good imaging modalities to detect intraperitoneal endometriosis lesions. Therefore, a diagnostic laparoscopy with resection/ablation of lesions is indicated in patients with dysmenorrhea refractory to treatments with NSAIDs and hormones.

DYSPNEA

Thomas G. Saba • Amy G. Filbrun

BASICS

DESCRIPTION

A subjective experience of breathing discomfort that consists of qualitatively distinct sensations that vary in intensity

PATHOPHYSIOLOGY

Abnormality in one of the following elements:

- Respiratory controller (breathing rate, depth)
- Ventilatory pump (chest wall, pleura, airways)
- Gas exchanger (alveoli, capillaries)
- Cardiovascular derangements (cardiac output)

ETIOLOGY

- Respiratory
 - Upper airway
 - Infection (croup, tracheitis, peritonsillar abscess, epiglottitis)
 - Foreign body
 - Anaphylaxis
 - Anatomic abnormalities
 - Vocal cord dysfunction (VCD)
 - Lower airway
 - Asthma
 - Aspiration
 - Airway malacia
 - Hemorrhage
 - Internal/external fixed compression (tumor, cyst, vascular)
 - Parenchymal lung disease
 - Infection (viral, bacterial, fungal)
 - Interstitial lung disease (ILD)
 - Atelectasis
 - Chronic lung disease (chronic obstructive pulmonary disease)

- [COPD], cystic fibrosis)
- Chest wall disorder
 - ▣ Neuromuscular weakness (Duchenne muscular dystrophy [DMD], spinal muscular atrophy [SMA])
 - ▣ Scoliosis
 - ▣ Pectus excavatum
- Pleural
 - ▣ Pleural effusion
 - ▣ Pneumothorax
- Cardiovascular
 - Cardiac
 - ▣ Elevated pulmonary venous pressure
 - ▣ Congestive heart failure (CHF)
 - Vascular
 - ▣ Pulmonary hypertension (PHTN)
 - ▣ Pulmonary embolism (PE)
- Toxic/metabolic
 - Metabolic acidosis (diabetic ketoacidosis, salicylate intoxication, renal tubular acidosis [RTA])
 - Renal failure causing fluid overload
- Other
 - Anemia
 - Deconditioning
 - Obesity
 - Panic attack
 - Pregnancy
 - Trauma
 - Gastroesophageal reflux disease (GERD)

DIAGNOSIS

APPROACH TO PATIENT

- Secure the airway and address life-threatening emergencies.
- Identify those who will need intensive/emergency care and those who can be worked up in the office.

- Distinguish new-onset dyspnea from deterioration of chronic disease.
- Detailed history is key to diagnosis.

HISTORY

- Onset
 - Recurrent, discrete episodes associated with anxiety
 - Panic attacks
 - Sudden
 - Foreign body, pneumothorax
- Associated signs and symptoms
 - “Tightness”
 - Bronchoconstriction (asthma)
 - Stridor
 - Upper airway obstruction
 - Wheezing
 - Lower airway obstruction
 - Chest pain
 - Pneumothorax, PE, pleural effusion
 - Hemoptysis
 - Hemorrhage
 - Worse when supine
 - Pulmonary edema
- Temporal association
 - Exercise-induced
 - VCD, asthma, deconditioning, GERD
 - Nocturnal
 - Asthma, GERD
 - Persistent and progressive
 - Neuromuscular disease, ILD
- Infectious signs and symptoms
 - Fever, cough, rhinorrhea
 - Pneumonia, bronchiolitis
 - Stridor, cough, rapid onset
 - Croup, tracheitis, abscess, epiglottitis
- Gastrointestinal signs and symptoms
 - Choking, gagging with feeds

- Aspiration
- Epigastric pain, discomfort
 - GERD
- Exposures
 - Salicylates, allergens
- PE risk factors include immobilization, surgery, smoking, pregnancy, central catheter, history of deep vein thrombosis
- History of cardiac disease
 - PHTN, CHF
- Diabetes history
 - Polyuria, polydipsia, polyphagia

PHYSICAL EXAM

- Vital signs, oxygen saturation, temperature
 - Fever
 - Infection
 - Hypoxia suggestive of pulmonary and cardiac causes
- Weight, BMI
 - Chronic disease, obesity
- Breath sounds
 - Generalized decreased air entry
 - Bronchoconstriction, atelectasis
 - Localized decreased intensity
 - Pneumothorax, pleural effusion, local obstruction, elevated hemidiaphragm, foreign body, pneumonia
 - Egophony, bronchial breath sounds
 - Consolidation/pneumonia
 - Wheezing
 - Bronchoconstriction, foreign body, bronchiolitis
 - Crackles
 - Infection, ILD (especially if crackles don't clear with coughing)
 - Barking quality of cough
 - Croup
 - Stridor
 - Upper airway obstruction
- Cardiac exam

- Crackles, peripheral edema, hepatomegaly, gallop
 - CHF
- Loud P₂
 - PHTN
- Extremities
 - Clubbing
 - Chronic pulmonary/cardiac disease
 - Cyanosis
 - Shunting
 - Calf tenderness
 - DVT
- Musculoskeletal
 - Generalized muscle weakness
 - DMD, SMA, other neuromuscular diseases
- Head and neck
 - Pharyngeal cobblestoning
 - GERD, allergic rhinitis
 - Allergic shiners, nasal crease, swollen nasal turbinates
 - Allergic rhinitis
 - Rhinorrhea
 - Allergic rhinitis, infection
 - Pharyngeal erythema, uvular deviation
 - Peritonsillar abscess

DIAGNOSTIC TESTS & INTERPRETATION

Lab

First line

- Arterial blood gas
 - Hypercarbia suggests impending respiratory failure; distinguishes metabolic from respiratory acidosis
- Complete blood count with differential
 - Anemia; leukocytosis with left shift is a sign of infection.
- Glucose
 - Hyperglycemia can lead to diabetic ketoacidosis (DKA).
- Viral testing (polymerase chain reaction [PCR], direct fluorescent antibody [DFA], culture)

- Diagnose viral infection; consider influenza in winter months.

Special considerations

- B-type natriuretic peptide (BNP)
 - Diagnostic marker to help recognize heart disease when access to echocardiography not readily available

Imaging

First line

- Chest radiograph
 - Identify pleural effusion, pneumothorax, consolidation, cardiomegaly, hyperinflation

Special considerations

- CT
 - High-resolution CT to diagnose ILD; spiral CT angiography to diagnose PE
- Echocardiography
 - Signs of PHTN; heart failure; structural abnormalities

Diagnostic Procedures/Other

- Pulmonary function tests
 - Spirometry
 - Obstructive lung disease (asthma); distinguish upper from lower airways obstruction
 - Lung volumes
 - Restrictive lung disease (ILD, neuromuscular and chest wall diseases)
 - Diffusion capacity
 - ILD
 - Mean inspiratory and expiratory pressure
 - Neuromuscular disease/weakness
- Bronchoscopy with bronchoalveolar lavage (BAL)
 - Dynamic visualization of airways to diagnose fixed (vascular) or dynamic (bronchomalacia) airway compression; bacterial, viral, and fungal cultures; lipid-laden macrophages (aspiration); hemosiderin-laden macrophages (hemorrhage)
- Electrocardiogram
 - Readily available test to rapidly diagnose heart disease

- Cardiopulmonary exercise testing
 - Indicated when initial evaluation fails to yield diagnosis; distinguish cardiac and respiratory causes and deconditioning

TREATMENT

- Secure airway and stabilize the patient.
- Treatment should be directed at the underlying cause of dyspnea.
- Consider palliative/symptomatic treatment once underlying or reversible cause has been addressed.

MEDICATIONS

- Opioids (parenteral/oral/inhaled)
- Anxiolytics

ADDITIONAL TREATMENT

General Measures

- Oxygen
- Pulmonary rehabilitation
- Movement of cool air (face fan)

ALERT

In patients with hypercapnic chronic respiratory failure, hypoxemia might be the primary drive to breathe; supplemental oxygen will remove the hypoxic respiratory drive and cause apnea.

ISSUES FOR REFERRAL

- Unstable vital signs, unsecure airway, inability to oxygenate, and need for critical care services
- Surgical consultation for foreign body removal with rigid bronchoscopy
- Pulmonary referral for severe asthma, hemorrhage, ILD, CF, DMD, SMA, flexible bronchoscopy, chronic mechanical ventilation
- Cardiac referral for cardiac disease, PHTN
- Endocrinology referral for diabetes
- Nephrology referral for RTA and renal failure

SURGERY/OTHER PROCEDURES

- Evacuation of tension pneumothorax with chest tube
- Pleural drainage/video-assisted thoracic surgery for loculated empyema
- Rigid bronchoscopy for foreign body retrieval
- Flexible bronchoscopy and laryngoscopy for visual diagnosis and BAL

CODES

ICD10

- R06.00 Dyspnea, unspecified
- R06.1 Stridor
- R06.2 Wheezing

FAQ

- Q: In most pediatric cases, is dyspnea pulmonary in nature?
- A: In most cases, yes. Nonetheless, a systematic approach looking at all organ systems should be employed when addressing a patient with dyspnea.
- Q: How does the etiology of dyspnea differ in adults?
- A: In adults, the most common causes of dyspnea are asthma, COPD, ILD, myocardial dysfunction, and obesity/deconditioning. Whereas asthma and obesity are common in children, COPD, ILD, and myocardial disease are much more common in adults.

DYSURIA

Stephanie Clark • Rebecca Ruebner

BASICS

DESCRIPTION

Painful urination

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Infectious
 - Cystitis
 - Viral infection
 - Gonorrhea
 - Chlamydia
 - Herpes simplex
 - Varicella
 - Tuberculosis
 - Candidiasis
 - Urethritis
 - Pinworms
 - Prostatitis
 - Balanitis
- Congenital/anatomic
 - Meatal stenosis
 - Urethral stricture
 - Posterior urethral diverticula
 - Urethral stones
 - Vesicovaginal fistula
 - Labial adhesions
- Toxic/environmental/drugs
 - Bubble bath urethritis
 - Spermicides, douches

- Cytosan
- Trauma
 - Diaper dermatitis
 - Foreign body
 - Bicycle injury
 - Masturbation
 - Sexual abuse
 - Irritation (e.g., from sand, tight pants)
- Tumor
 - Sarcoma botryoides
- Genetic/metabolic
 - Cystinuria
- Allergic/inflammatory
 - Food allergy
 - Stevens-Johnson syndrome
 - Contact dermatitis (e.g., poison ivy)
- Functional
 - Attention mechanism
 - Dysfunctional voiding
- Miscellaneous
 - Appendicitis
 - Hypercalciuria

APPROACH TO PATIENT

- General goal: Determine the cause and begin treatment.
 - Phase 1: Rule out common causes such as trauma, infection, chemical irritant, constipation, and masturbation.
 - Phase 2: Continue investigation—look for congenital or acquired problems that cause infection, strictures, or calculi.
 - Phase 3: Begin treatment.
- Hints for screening problems:
 - Ask about medications and food allergies.
 - Ask about special situations (e.g., travel, sand in bathing suit causing irritation).

HISTORY

- **Question:** Do the symptoms occur any special time of day?
- **Significance:** May indicate an attention mechanism if occurs before school
- **Question:** What kinds of medication do you take?
- **Significance:** Some medications (e.g., Cytosan) may cause irritation of the urethra.
- **Question:** Have there been any new foods or known food allergens?
- **Significance:** Milk is a possible food allergen that may cause dysuria. Citrus fruits may increase the acidity of the urine and cause dysuria in some patients. Best to determine whether symptoms regress on elimination of possible offending food.
- **Question:** Do you use bubble bath?
- **Significance:** Bubble bath may deplete the protective lipids in the urethra.
- **Question:** Any signs of bleeding?
- **Significance:** May indicate trauma, infection, or congenital anomalies. Calcium excretion may cause dysuria as well as hematuria.
- **Question:** Fever?
- **Significance:** Fever is a common sign of urinary tract infection (UTI).
- **Question:** Frequency?
- **Significance:** Both frequency and dysuria are common findings in UTIs.
- **Question:** Past history of urologic operations?
- **Significance:** Antireflux surgery may have a side effect of dysuria.
- **Question:** What have you taken for discomfort?
- **Significance:** Although cranberry juice is used for many urinary problems, the volume needed is usually more than what can be easily ingested.
- **Question:** Quality and strength of the urinary stream?
- **Significance:** Patients with posterior urethral valves may have urinary dribbling, poor urinary stream, difficulty potty training, or diurnal enuresis.
- **Question:** Sexual activity?
- **Significance:** Urethritis from gonorrhea or chlamydia
- **Question:** Frequency?

- Significance: It can sometimes be difficult to differentiate dysuria from frequency, which may cause an uncomfortable feeling or pressure that is described by the child as pain with urination.
- **Question:** Vaginal discharge?
- Significance: Vaginal discharge with dysuria suggests gonococcal or chlamydial infection.

PHYSICAL EXAM

- **Finding:** Any signs of redness or ecchymoses?
- Significance: May indicate trauma from masturbation or abuse
- **Finding:** Any bleeding?
- Significance: Seen in trauma, tumors, and infection
- **Finding:** Any change in behavior?
- Significance: May be an attention-seeking device
- **Finding:** Abnormal swelling?
- Significance: May occur in trauma or rare tumors
- **Finding:** Abnormal urethra?
- Significance: Prolapsed urethra or diverticula
- **Finding:** Grapelike structures in vagina?
- Significance: Sarcoma botryoides
- **Finding:** Abdominal pain?
- Significance: Intra-abdominal abscess or low-lying inflamed appendix may cause dysuria. A low-lying inflamed appendix may also cause bladder irritation and dysuria.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Test: Urinalysis
- Significance: In most UTIs, there are WBCs in the urine.
- Test: Urine culture
- Significance: Check for infection.
- Test: Metabolic screens
- Significance: If sediment shows crystals or if familial history of metabolic disease
- Test: Urinary screen for gonorrhea and chlamydia
- Significance: DNA amplification by polymerase or ligase chain

reaction on freshly voided urine has 95% sensitivity and 100% specificity.

Imaging

Ultrasound: not routinely requested unless a congenital anomaly is suspected

TREATMENT

ADDITIONAL TREATMENT

General Measures

- See treatment of [UTI](#), [vaginitis](#), urethritis
- Phenazopyridine (Pyridium) may be used for symptomatic relief while documenting cause of dysuria.
- Warm water sitz baths may be helpful for symptomatic treatment.

ISSUES FOR REFERRAL

- Evidence of congenital anomaly
- Increasing severity of symptoms
- Failure to respond to symptomatic or specific treatment

ADDITIONAL READING

CODES

ICD10

- R30.0 Dysuria
- N39.0 Urinary tract infection, site not specified
- N34.2 Other urethritis

FAQ

- Q: How does bubble bath cause dysuria?
- A: The bubble bath depletes lipids that protect the urethra, causing the tissue to swell and become inflamed.
- Q: Can allergies cause dysuria?
- A: It is difficult to directly prove allergies as a cause of dysuria; however, in some cases, elimination of certain foods such as spices, citrus fruits, or known skin allergens has improved symptoms.
- Q: How do children get infected with gonorrhea?
- A: This is a red flag for sexual abuse, which must be investigated.
- Q: Which viruses cause dysuria?
- A: Adenovirus has been associated with dysuria.

EARACHE

Vanessa S. Carlo

BASICS

DESCRIPTION

- Otolgia, classified as primary or secondary, means ear pain or an earache.
- Primary (or otogenic) otalgia is ear pain that originates inside the ear, either from the external auditory canal or from the middle ear structures.
- Secondary (or referred) otalgia is ear pain that originates from outside of the ear. Any anatomic area that shares innervation with the ear can be the primary source of perceived ear pain.

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

Primary otalgia

- Infectious
 - Acute otitis media (AOM)—most common cause of otalgia in children
 - Otitis externa—inflammation of external auditory canal, usually associated with swimming and/or localized trauma; second most common cause of otalgia in children
 - Cellulitis of the auricle—usually caused by *Streptococcus pyogenes*; typically involves the earlobe
 - Perichondritis—inflammation of the auricle without earlobe involvement
 - Furunculosis—infection of the cartilaginous portion of the external auditory canal. Most commonly caused by *Staphylococcus aureus*. Pain is usually made worse by chewing.
 - Mastoiditis—now a rare complication of AOM, characterized by the auricle being pushed out and forward, away from the head

- Myringitis (bullous myringitis)—inflammation of the tympanic membrane, usually with painful blisters on the eardrum
- Varicella and herpes zoster infection within the ear
- Herpes simplex virus infection within the ear
- Trauma
 - Blunt trauma
 - Laceration or abrasion—if inside the ear canal, usually due to cleaning with cotton swabs
 - Thermal injury—frostbite of the ear or burn from a heat source
 - Barotrauma—associated with pressure changes on airplanes and scuba diving
 - Traumatic perforation of the tympanic membrane—frequently presents with tinnitus
- Tumors—rare; usually associated with weight loss, voice changes, dysphagia, and persistent cervical lymphadenopathy
- Allergic/inflammatory
 - Otitis media with effusion
 - Eczema
 - Psoriasis
 - Allergic reaction to topical antibiotics and cerumenolytic agents
- Functional
 - Eustachian tube dysfunction—symptoms are due to pressure differences between the middle ear and the Eustachian tube.
- Miscellaneous
 - Foreign body—can lead to pain, fullness, and minor hearing loss
 - Impacted cerumen—may cause pain if the cerumen presses against the tympanic membrane

Note: Serous otitis media or otitis media with effusion (OME) is common in pediatrics but is usually painless. Children usually complain of fullness or hearing loss.

Secondary otalgia

- Infectious
 - Dental infections—cavities, abscesses, gingivitis
 - Pharyngitis
 - Parotitis

- Tonsillitis
- Peritonsillar abscess
- Retropharyngeal abscess
- Sinusitis
- Cervical lymphadenitis
- Neck abscess
- Stomatitis
- Sialadenitis
- Ramsay Hunt syndrome—viral neuritis of the facial nerve secondary to herpes zoster infection
- Trauma
 - Dental trauma
 - Postsurgical—tonsillectomy, adenoidectomy
 - Oropharyngeal trauma—penetrating injuries, burns
 - Neck and cervical spine injuries
- Allergic/inflammatory
 - Allergic rhinitis
 - Cervical spine arthritis
 - Subacute thyroiditis
 - Esophagitis—secondary to gastroesophageal reflux
 - Bell palsy
- Functional
 - Temporomandibular joint (TMJ) dysfunction—less common in children. Pain is usually unilateral and aggravated by chewing and biting.
- Miscellaneous
 - Foreign body—in oropharynx or esophagus
 - Aphthous ulcers
 - Esophagitis
 - TMJ disease
 - Migraine
 - Aural neuralgia
 - Pillow otalgia (otalgia from sleep position)
 - Psychogenic pain

APPROACH TO THE PATIENT

The first decision that must be made is whether the patient's symptoms require emergent, urgent, or nonurgent intervention. Emergency treatment is rarely required for pediatric patients with otalgia.

- **Phase 1:** Thorough history—must include a full assessment of ear symptoms, followed by questions to determine possible involvement of other head and neck structures
- **Phase 2:** Physical exam—thorough examination of external and internal ear, followed by inspection of the head, neck, and inside of the mouth
- **Phase 3:** Treatment of identifiable conditions
- **Phase 4:** Referral to otolaryngologist (ENT physician), dentist, or other specialist as needed

HISTORY

- **Question:** Duration of symptoms?
- Significance: acute (more likely infection or trauma) versus chronic
- **Question:** Quality of the pain?
- Significance:
 - Constant (more likely otogenic) versus intermittent (more likely referred)
 - Dull (more likely due to inflammation) versus sharp (more likely due to trauma or neuralgia)
- **Question:** Severity of pain?
- Significance:
 - Severe—usually otogenic
 - Mild to moderate—more likely to be referred

Worsening factors

- **Question:** Movement of auricle or pressure on tragus?
- Significance: Characteristic of otitis externa; can also be associated with furunculosis.
- **Question:** Movement of the jaw (biting, chewing)?
- Significance: TMJ dysfunction; furunculosis

Associated symptoms

- **Question:** Fever?
- Significance: Infection
- **Question:** Upper respiratory infection (URI) symptoms?

- Significance: AOM or OME
- **Question:** Sore throat?
- Significance: Referred otalgia
- **Question:** Ear discharge, tinnitus, or vertigo?
- Significance: Otogenic causes
- **Question:** Mouth pain?
- Significance: Dental issues or stomatitis
- **Question:** Hoarseness?
- Significance: Gastroesophageal reflux
- **Question:** Multiple somatic complaints?
- Significance: Psychogenic
- **Question:** Recent swimming?
- Significance: Otitis externa
- **Question:** Recent travel? Hobbies?
- Significance:
 - Barotrauma from scuba diving or air travel
 - Wrestling—auricular trauma
- **Question:** History of recurrent AOM or OME?
- Significance: Cholesteatoma

PHYSICAL EXAM

- **Finding:** Erythematous, dull, bulging tympanic membrane, with decreased mobility?
- Significance: Suggestive of AOM
- **Finding:** Retracted, immobile tympanic membrane?
- Significance: Suggestive of OME or eustachian tube dysfunction
- **Finding:** Pain with pressure on the tragus or traction on the pinna?
- Significance: Suggestive of otitis externa or furunculosis
- **Finding:** Erythema and edema of the external auditory canal?
- Significance: Suggestive of otitis externa
- **Finding:** Purulent discharge in external auditory canal?
- Significance: Suggestive of otitis externa or AOM with a ruptured tympanic membrane
- **Finding:** Redness, swelling, and/or tenderness of the auricle?
- Significance:
 - With earlobe involvement—cellulitis

- Without earlobe involvement—perichondritis
- **Finding:** Swelling behind the pinna with its lateral displacement?
- Significance: Suggestive of mastoiditis
- **Finding:** Normal ear exam?
- Significance: Suggestive of secondary otalgia, thus other possible sources must be carefully examined
- **Finding:** Multiple dental caries?
- Significance: May be the source of pain; can indicate the presence of a dental abscess
- **Finding:** Foreign body within the ear or in the oropharynx?
- Significance: May be the source of pain from direct pressure or secondary to inflammation
- **Finding:** Enlarged, asymmetric tonsils or uvular deviation from midline?
- Significance: Suggestive of tonsillitis or peritonsillar abscess

Look for signs of trauma inside or outside of the ear.

DIAGNOSTIC TESTS & INTERPRETATION

Labs, imaging studies, and other diagnostic tests are usually unnecessary as a thorough history and physical exam can lead to a diagnosis in the majority of cases.

- **Test:** Culture of ear discharge
- Significance: Indicated when otitis externa or AOM with perforation of the tympanic membrane does not resolve as expected with routine antibiotic treatment
- **Test:** Audiometry
- Significance: Evaluate for hearing loss, which would suggest primary otalgia
- **Test:** Tympanometry
- Significance: Evaluate for OME, eustachian tube dysfunction, or tympanostomy tube obstruction

Imaging

- CT scan: rarely needed
 - CT of neck—evaluate for retropharyngeal abscess, mass, or hematoma

- CT of sinuses—evaluate for sinusitis
- CT of temporal bone—evaluate for AOM, mastoiditis, and other bony pathology
- MRI: rarely needed unless intracranial lesion is suspected

TREATMENT

ADDITIONAL TREATMENT

General Measures

- Therapy is directed at the identified underlying cause.
- Pain medications such as acetaminophen, ibuprofen, or topical benzocaine are important because many of the infectious causes are exquisitely painful.
- Observation without antibiotic therapy (“watchful waiting”) is indicated in certain groups of children with AOM.

EMERGENCY CARE

- Rarely needed with most causes of otalgia but may be required if
 - Potential airway compromise from foreign body, mass, or abscess
 - Significant trauma—possible basilar skull fracture
 - Infection with a toxic-appearing child
- For all of the above situations, first establish “ABCs” as needed, hospitalize, and consult ENT promptly.

ISSUES FOR REFERRAL

Referral to ENT when otalgia is primary in origin and any of the following:

- Pain with unexplained hearing loss, vertigo, or tinnitus
- Unexplained or persistent otorrhea
- Suspected neoplasm
- History suggestive of severe barotrauma
- AOM with complications
- Foreign bodies that cannot be removed easily from the ear
- Potential for auricle destruction (e.g., perichondritis may lead to permanent deformation, cauliflower ear)
- Persistent ear pain without an identifiable source should prompt a

referral.

CODES

ICD10

- H92.09 Otolgia, unspecified ear
- H66.90 Otitis media, unspecified, unspecified ear
- H60.90 Unspecified otitis externa, unspecified ear

FAQ

- Q: What are the most common organisms that cause AOM?
- A:
 - *Streptococcus pneumoniae*
 - *Haemophilus influenzae*
 - *Moraxella catarrhalis*
 - Viruses
- Q: What are the most common organisms that cause otitis externa?
- A:
 - *Pseudomonas aeruginosa*
 - *Staphylococcus aureus*

- Staphylococcus epidermidis
- Gram-negative rods
- Fungal (Aspergillus) or yeast (Candida)—rare
- Q: What is the most common cause of referred ear pain?
- A: Dental disease

EDEMA

Stephanie Clark • Rebecca Ruebner

BASICS

DESCRIPTION

Presence of abnormal amount of fluid in the interstitial spaces of the body; usually secondary to low albumin, obstruction of venous or lymphatic channels, or trauma

DIAGNOSIS

DIFFERENTIAL DIAGNOSIS

- Localized
 - Trauma: pressure or sun damage
 - Infection
 - Allergy
 - Lymphatic obstruction (less common)
 - Filariasis
 - Radiation therapy
 - Bee stings or insect bites
 - Sickle cell dactylitis
- Generalized
 - Congenital: lymphatic obstruction of legs or thoracic duct
 - Infection: hepatitis and liver failure; pericarditis
 - Toxic, environmental, drugs
 - Sodium poisoning
 - Toxic effect on liver and/or heart (chemotherapy)
 - Cirrhosis
 - Drug reaction
 - Tumor
 - Obstruction of venous return from enlarged abdominal lymph nodes or tumor
 - Allergic/inflammatory: protein-losing enteropathy

- Renal
 - Nephrotic syndrome
 - Renal failure
 - Acute glomerulonephritis
- Cardiac
 - Congestive heart failure (CHF)
 - Pericarditis
- GI
 - Intestinal protein loss
 - Postpericardiotomy or congenital heart surgery
 - Hepatobiliary disease
- Endocrine: hypothyroidism

ETIOLOGY

- Excessive losses of protein
 - Renal losses
 - GI losses
- Inadequate production of protein
 - Liver disease
 - Malnutrition
- Local trauma
- Increased hydrostatic pressure
 - CHF
 - Cirrhosis
 - Pericardial effusion
 - Post–cardiac surgery
 - Venous obstruction
 - Superior vena cava syndrome
 - Deep vein thrombosis
- Lymphatic obstruction

APPROACH TO THE PATIENT

Determine the cause of swelling: Is it localized? Are there any sources of protein loss? Is there underproduction of protein?

- **Phase 1:** Is the swelling localized as seen in trauma, lymphatic, or venous obstruction?

- **Phase 2:** Are there urinary or GI losses?
 - Associated with decreased serum albumin
 - Most likely source of loss is renal disease, less frequently GI losses
- **Phase 3:** Search for other causes of edema, such as CHF, cirrhosis, lymphatic obstruction

HISTORY

- **Question:** Is the edema localized or generalized?
- Significance: See “[Differential Diagnosis](#)”
- **Question:** Is the patient asymptomatic or in some distress specifically because of the edema?
- Significance: Determine treatment urgency
- **Question:** Evidence of cardiac, renal, or GI disease?
- Significance: Major causes of edema
- **Question:** Waist size has become larger, difficulty putting shoes on, clothes too tight?
- Significance: Evidence of edema in body
- **Question:** Excess salt intake in diet?
- Significance: In some patients, contributes to edema
- **Question:** Shortness of breath?
- Significance: There may be ascites, which compresses the diaphragm, or pleural effusions.
- **Question:** Chronic diarrhea?
- Significance: Seen in protein-losing enteropathy or lymphatic obstruction
- **Question:** Has a urinalysis been performed in the past?
- Significance: May help date the onset of the problem
- **Question:** Swelling around the eyes or face?
- Significance: May suggest allergies but should also consider other causes of edema such as nephrotic syndrome
- **Question:** Anemia?
- Significance: Seen in protein-losing enteropathy

PHYSICAL EXAM

- **Finding:** Lumbosacral area, pretibial, scrotum/labia?
- Significance: Dependent edema

- **Finding:** Percussion of chest?
- Significance: Pleural effusion
- **Finding:** Shifting dullness?
- Significance: Early sign of ascites
- **Finding:** Soft ear cartilage?
- Significance: Common finding in nephrotic syndrome
- **Finding:** Pitting edema?
- Significance: Seen in cases of protein loss
- **Finding:** Nonpitting edema?
- Significance: May be caused by venous/lymphatic obstruction or salt poisoning.

DIAGNOSTIC TESTS & INTERPRETATION

- **Test:** Dipstick urinalysis
- Significance: If there is generalized edema with heavy proteinuria, this is suggestive of nephrotic syndrome.
- **Test:** Serum albumin
- Significance:
 - Hypoalbuminemia in the setting of edema and proteinuria supports diagnosis of nephrotic syndrome.
 - If there is generalized edema with no proteinuria but hypoalbuminemia, consider cardiac, GI, or hepatobiliary disease and direct additional studies to evaluate these 3 organ systems specifically.
 - If there is either localized edema or generalized edema but a normal urinalysis and a normal serum albumin, consider other unusual causes for edema, such as mechanical or lymphatic obstruction, certain endocrine disorders, or the effects of drugs or toxins.
- **Test:** Alpha-1-antitrypsin in stool
 - Significance: Seen in protein-losing enteropathy
- **Test:** Cholesterol
 - Significance: Only high in hypoalbuminemia associated with nephrotic syndrome

TREATMENT

ADDITIONAL TREATMENT

General Measures

- Moisturize skin.
- Avoid pressure sores.
- Decrease sodium intake.
- Active or passive leg exercise to avoid venous thromboses.
- If edema is massive, the patient may awaken with swollen eyelids. Place blocks under the head of the bed to keep the patient's head elevated.
- If there is scrotal edema, jockey shorts will help support the scrotum and protect the skin from breaking down.
- For severe edema with respiratory distress, severe abdominal discomfort, or severe scrotal edema, consider treatment with albumin and/or furosemide infusion.

ISSUES FOR REFERRAL

- Nephrotic syndrome—pediatric nephrologist
- Protein-losing enteropathy or hepatobiliary disease—pediatric gastroenterologist
- CHF—pediatric cardiologist
- Endocrine-mediated edema—pediatric endocrinologist
- Lymphatic or other mechanical obstructions—vascular surgeon or pediatric surgeon

INITIAL STABILIZATION

Any child or adolescent with an edema-forming state that compromises either cardiorespiratory function or the vascular integrity of a peripheral organ or limb should be referred immediately to an appropriate specialist for emergency care.

CODES

ICD10

- R60.9 Edema, unspecified
- R60.0 Localized edema
- R60.1 Generalized edema

FAQ

- Q: At what level of serum albumin does edema occur?
- A: Edema is generally associated with serum albumin <2.5 g/dL.
- Q: Why does pericardial effusion cause edema?
- A: Pericardial effusion is associated with decreased lymphatic flow and increased venous pressure.

EHRLICHIOSIS AND ANAPLASMOSIS

Gordon E. Schutze

BASICS

DESCRIPTION

Two common clinically described infections are human monocytic ehrlichiosis (HME), caused by *Ehrlichia chaffeensis*, and human granulocytic anaplasmosis (HGA), caused by *Anaplasma phagocytophilum*. Human ehrlichiosis can be caused by 2 other *Ehrlichia* species in the United States: *ewingii* and *muris-like* agent.

EPIDEMIOLOGY

- HME typically occurs in the midwest, south central, and southeastern United States, mirroring the pattern of Rocky Mountain spotted fever (RMSF). In addition, it has been found in Europe, South America, Asia, and Africa.
- HGA typically occurs in the north central, northeastern United States, and northern California, similar to Lyme disease. Most patients are infected during April through September, the months of greatest tick and human outdoor activity.
- A second peak of HGA occurs from late October to December.

GENERAL PREVENTION

- Avoid tick-infested areas.
- Clothes should cover arms and legs.
- Use tick repellents, but with caution in young children.
- A thorough body search should always be done after returning from a tick-infested area:
 - If a tick is found, the area should be cleaned with a disinfectant, and the tick should be removed immediately.
 - To remove the tick, grasp the tick at the point of origin with forceps, staying as close to the skin as possible.
 - Applying steady, even pressure, slowly pull the tick off the skin. After the tick has been removed, clean the skin with a disinfectant.

- Instruct parents to seek medical attention only if symptoms develop.
- No vaccine is available.

PATHOPHYSIOLOGY

- Obligate intracellular, pleomorphic, gram-negative bacteria.
- Transmission to humans by a tick vector
- Incubation period from 2 to 21 days
- HME infects monocytes and macrophages, whereas HGA infects neutrophils.
- The bacteria reside and divide within cytoplasmic vacuoles of circulating leukocytes, called morulae.
- There is overinduction of the inflammatory and immune response, resulting in clinical manifestations of disease, including multiorgan system involvement.

ETIOLOGY

- HME is transmitted by *Amblyomma americanum*, the Lone Star tick. The white-tailed deer is the major reservoir.
- HGA is transmitted by *Ixodes scapularis*, the black-legged or deer tick, or the Western black-legged tick (*Ixodes pacificus*). Small mammals such as the white-footed mouse are the major reservoirs.
- Congenital infection is very rare but has been described in case reports.

DIAGNOSIS

Classic presentation: fever, headache, and myalgias, followed by the development of a progressive leukopenia, thrombocytopenia, and anemia

HISTORY

- History of tick bite or exposure to wooded areas that are endemic for tick-borne diseases is helpful but is not always present.
- Fever, severe headache, chills, and myalgias
- Complaints of abdominal pain, vomiting, anorexia, and diarrhea may be present.
- Cough and sore throat are often described.

PHYSICAL EXAM

- Fever is described in all children.
- A pleomorphic rash occurs in ~66% of pediatric patients with HME:
 - Rash is described as macular, maculopapular, petechial, erythematous, vesicular, or a combination of these.
 - Usually distributed on the trunk and extremities; spares palms, soles, and face
- Mental status change due to meningoencephalitis
- Cardiac murmur (II/VI systolic ejection murmur at the left lower sternal border)
- Hepatosplenomegaly
- Conjunctival or throat injection

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- CBC with differential (with smear)
 - Thrombocytopenia, $<150,000/\text{mm}^3$ (77–92% incidence)
 - Lymphopenia, $<1,500/\text{mm}^3$ (75%) with HME
 - Neutropenia, $<4,000/\text{mm}^3$ (58–68%) with HGA
 - Anemia, hematocrit $<30\%$ (38–42%)
 - Intracytoplasmic morulae within leukocytes (20–60%), more common with HGA
- Electrolytes with BUN and creatinine: hyponatremia (33–65%)
- Liver function tests: elevated alanine aminotransferase, $>55 \text{ U/L}$ (90%)
- Coagulation labs, type and cross, as indicated
- CSF
 - Leukocytosis, with an average cell count of $100/\text{mm}^3$
 - Lymphocytic predominance
 - Elevated protein and borderline low glucose (less common in children, more common in adults)
 - Microbiology cultures are negative.
 - Intraleukocyttoplasmic Ehrlichia microorganisms (morulae) have been described on CSF smears.
- Serum studies
 - Acute and convalescent antibody titers of Ehrlichia (a 4-fold rise or fall is considered positive) obtained 2–4 weeks apart
 - An acute antibody titer of $\geq 1:128$ is considered diagnostic.

- Polymerase chain reaction is also available for both HME and HGA.
- The detection of intraleukocytoplasmic Ehrlichia microcolonies (morulae) on blood or bone marrow monocytes or granulocytes is diagnostic but is not present in all patients.

Diagnostic Procedures/Other

- Bone marrow biopsy is not necessary to diagnose the ehrlichiosis but may be carried out amid concern for other hematologic diseases.
- Bone marrow is usually hypercellular, but normocellularity and hypocellularity have also been found.

ALERT

- Failing to consider the diagnosis of ehrlichiosis or a delay in treatment pending confirmatory serum titers increases morbidity and mortality.
- Thus, treatment should be started if infection is suspected based on history, physical, and initial laboratory data.
- Alternative diagnoses should be considered in children who do not rapidly improve with doxycycline.
- Simultaneous infections have been documented with HGA and Lyme disease.

DIFFERENTIAL DIAGNOSIS

- Tick-borne infection
 - RMSF
 - Tularemia
 - Relapsing fever
 - Lyme disease
 - Colorado tick fever
 - Babesiosis
- Other infections
 - Toxic shock syndrome
 - Kawasaki disease
 - Meningococcemia
 - Pyelonephritis
 - Gastroenteritis
 - Hepatitis

- Leptospirosis
- Epstein-Barr virus
- Influenza
- Cytomegalovirus
- Enterovirus
- Streptococcus pharyngitis
- Miscellaneous
 - Leukemia
 - Idiopathic thrombocytopenia purpura
 - Hemolytic uremic syndrome

TREATMENT

MEDICATION

First Line

- Doxycycline, either PO or IV
- Drug of choice regardless of age of child who is severely ill
- Dose: 4.4 mg/kg/day divided q12h (max dose 200 mg q12h)
- Treatment duration: minimum 5–10 days. Continue for 3–5 days after defervescence, longer if there is CNS involvement.

Second Line

- Rifampin has been reported to be an effective antibiotic for children <8 years of age who are less toxic and are experiencing an HGA infection.
- Dose: 20 mg/kg/day divided q12h for 5–10 days
- This is also the drug of choice for pregnant mothers.
- Unlike Lyme disease, neither amoxicillin nor ceftriaxone has been shown to be effective for the treatment of ehrlichiosis.

ADDITIONAL TREATMENT

General Measures

- Volume and BP medications as needed
- Intubation for respiratory failure
- Dialysis for renal failure
- Platelets for thrombocytopenia
- Packed red blood cells for anemia

- Fresh frozen plasma, cryoprecipitate, and vitamin K for DIC
- Antifungal or antibiotics for secondary infections

ONGOING CARE

PROGNOSIS

- >60% of patients are hospitalized.
- Case fatality rate for HME is 2–5%; for HGA, 7–10%.
- Elevated BUN and creatinine have been associated with a more severe course.
- Children appear to have an excellent outcome: Blood, renal, and liver abnormalities resolve in 1–2 weeks after initiating antibiotics.
- Cognitive and behavioral problems have been reported.
- Neuropathy has been described.

COMPLICATIONS

- Neurologic
 - Headache, described as severe
 - Mental status changes
 - Seizures
 - Coma
 - Focal neurologic findings
 - Cognitive learning deficits
- Hematologic
 - Disseminated intravascular coagulation (DIC)
 - Thrombocytopenia
 - Leukopenia
 - Lymphopenia
 - Anemia
- GI
 - Hemorrhage
 - Elevated liver enzymes
 - Hepatosplenomegaly
- Respiratory
 - Pulmonary hemorrhage

- Interstitial pneumonia
- Pleural effusions
- Noncardiogenic pulmonary edema
- Infectious
 - Fungal superinfection
 - Nosocomial infections
 - Opportunistic infections
- Renal
 - Renal failure
 - Proteinuria
 - Hematuria
- Cardiac
 - Cardiomegaly
 - Murmurs

CODES

ICD10

- A77.40 Ehrlichiosis, unspecified
- A77.41 Ehrlichiosis chafeensis [E. chafeensis]
- A77.49 Other ehrlichiosis

FAQ

- Q: If a tick is removed from my child, should antibiotics be started?
- A: No. Antibiotics should be started if a child becomes symptomatic because prophylactic use of antimicrobial agents will not prevent the development of disease.
- Q: What is the most common chief complaint in children with ehrlichiosis?
- A: Intense, unremitting headache and fever are the most common features.

ENCEPHALITIS

Lily C. Wong-Kisiel • Elaine C. Wirrell

BASICS

DESCRIPTION

Encephalitis is inflammation of the brain parenchyma, which results in alterations in mental status, motor or sensory symptoms, speech problems, or seizures. This inflammation may be due to direct brain invasion by an infectious pathogen or immune-mediated from an inflammatory processes due to acute or chronic illnesses.

EPIDEMIOLOGY

- Exact incidence is unknown, but infants and children are predominantly affected.
- Encephalitis due to enterovirus or arbovirus has a peak incidence between summer and early autumn. Many cases of viral encephalitis occur in epidemics.

GENERAL PREVENTION

- Routine immunization for measles, mumps, rubella, and influenza and, if travelling to endemic area (e.g., Southeast Asia), consideration of immunization for Japanese encephalitis
- Careful hand washing, avoid tick and mosquito exposure (DEET [N,N-diethyl-meta-toluamide] repellent, mosquito netting, appropriate dress), and insect control (drainage of stagnant water, insecticides)

PATHOPHYSIOLOGY

- Transmission of infectious pathogens can be by the blood-borne route, by retrograde spread through peripheral nerves (such as HSV or rabies), or rarely by direct inoculation of the brain.
- Encephalitis may also result indirectly, by immune-mediated injury due to parainfectious (i.e., acute disseminated encephalomyelitis or mycoplasma) or inflammatory/paraneoplastic causes (i.e., anti-NMDA receptor encephalitis). Such immune-mediated mechanisms involve

cytokine effects and cytotoxic antibodies on neurons.

ETIOLOGY

- In most cases, the underlying cause remains unknown. Of those with known etiology, the majority are due to viral agents, followed by bacterial, autoimmune, parasitic, and fungal causes.
- The most common viral causes include HSV 1 and 2, enteroviruses, arboviruses (West Nile virus [WNV]), and other herpesviruses (CMV, EBV, HHV-6, VZV). HSV-1 typically presents with focal seizures, often of temporal lobe origin and encephalopathy. HSV-2 is the predominant cause of neonatal HSV infection. Enteroviruses and arboviruses typically cause disease in the summer and fall. WNV presents as an acute flaccid paralysis, extrapyramidal symptoms, and cranial nerve palsies. Other viruses may be considered given specific historical features (rabies with animal bite or bat exposure or with prominent hydrophobia) or history of travel (Japanese encephalitis virus).
- Bacterial causes include *Listeria*, *Francisella tularensis*, *Bartonella*, *Mycobacterium*, *Rickettsia*, *Mycoplasma*, *Borrelia*, and *Chlamydia*.
- Fungal and parasitic causes include *Cryptococcus*, *Blastomyces*, *Histoplasma*, *Paracoccidioides*, *Naegleria*, *Toxoplasma*, *Plasmodium*, and *Toxocara*.
- Parainfectious etiologies include acute disseminated encephalomyelitis (ADEM), acute hemorrhagic leukoencephalitis, postinfectious cerebellitis, and *Mycoplasma* encephalopathy. ADEM typically presents with encephalopathy and focal neurologic symptoms, with an MRI showing multifocal white matter lesions.
- Other inflammatory or paraneoplastic etiologies include anti-NMDA receptor encephalitis, voltage-gated potassium channel complex antibody, aquaporin-4 autoimmunity, SREAT (steroid-responsive encephalopathy associated with thyroid disease), systemic lupus erythematosus, and other vasculitis. Anti-NMDA receptor encephalitis typically presents subacutely with encephalopathy, sleep disturbance, seizures, perioral dyskinesias, and autonomic disturbances.

DIAGNOSIS

HISTORY

- Symptoms include fever, headache, photophobia, altered mental status, irritability, gait disturbance, and seizures.
- Ask for focal neurologic symptoms. A recent viral illness, recent travel, animal exposures, tick or mosquito bites, immunizations, and immune status may provide clues to etiology.
- A history of maternal herpes infection or prolonged rupture of membranes should be queried in neonates.

PHYSICAL EXAM

- Hypertension, bradycardia, or apnea may suggest impending herniation due to brain swelling.
- Altered mental status is the hallmark of encephalitis and ranges from mild confusion to stupor and coma. Distinguishing infectious from postinfectious encephalitis usually cannot be done reliably on clinical grounds.
- Specific neurologic findings suggestive of a specific etiology include focal seizures and focal neurologic findings (HSV); hydrophobia, pharyngeal spasms, and mood disturbance (rabies); facial nerve palsy (Lyme disease); flaccid paralysis or polio-like syndrome (WNV); and ataxia (VZV).
- Nonneurologic findings suggesting a specific etiology include respiratory symptoms (Mycoplasma), adenopathy and splenomegaly (EBV), petechial skin rash (Rickettsia), morbilliform rash (measles), erythematous maculopapular rash (enterovirus), and parotitis (mumps).

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Routine labs such as electrolytes, glucose, renal and liver function, and CBC are usually nonspecific.
- Selected serologic testing depending on the suspected agent (e.g., WNV and Mycoplasma) can provide confirmatory diagnosis of underlying etiology.
- Toxicology screen should be done to rule out overdose or toxin

exposure as the cause for altered mental status.

- Lumbar puncture is performed urgently, once the patient is stabilized and signs and symptoms of intracranial pressure are excluded (broad-spectrum treatment should commence if these conditions are not met).
- In addition to measuring opening pressure (frequently elevated), other studies should include CSF cell count and differential (lymphocytic predominance suggests a viral process, whereas neutrophilic predominance suggests bacterial or early viral processes), red blood cells (in the absence of a traumatic tap, red blood cells are suggestive of necrotizing encephalitis associated with HSV), protein (often elevated), glucose (usually normal), Gram stain and bacterial culture (20% of patients with suspected encephalitis are diagnosed with bacterial meningitis), and HSV polymerase chain reaction (PCR). Initial studies may be normal, which does not rule out the diagnosis of encephalitis if clinical suspicion is high.
- Other PCR-based tests on CSF including enterovirus, *Borrelia burgdorferi*, and WNV may be considered depending on the situation.
- In immunocompromised hosts, CSF should be sent for fungal stains and culture (and serum for cryptococcal serum antigen).
- In those patients suspected of paraneoplastic etiology, an extended panel of autoimmune antibodies should be investigated in the serum and CSF.

Imaging

Imaging is performed urgently to rule out surgically remediable conditions (e.g., abscess or hematoma). MRI (or if not available, CT) of the brain with and without contrast medium is preferred. Neuroimaging can be normal or demonstrate focal or diffuse parenchymal enhancement (HSV-2 has a preference for the medial temporal lobe).

Diagnostic Procedures/Other

- An EEG usually shows diffuse generalized slowing. Findings of periodic lateralized discharges are suggestive but not diagnostic of HSV.
- Brain biopsy: rarely performed

DIFFERENTIAL DIAGNOSIS

Several conditions can resemble encephalitis including metabolic (acute electrolyte disturbance, inborn errors of metabolism), toxic (ingestions), structural (acute obstructive hydrocephalus or shunt obstruction), vascular (cerebral vasculitis, ischemic or hemorrhagic stroke, septic embolization, sinus thrombosis), endocrine (hypothyroid crisis, pituitary infarction), infectious (bacterial meningitis, brain abscess, subdural empyema, viral meningitis), or epileptic disorders (status epilepticus).

TREATMENT

MEDICATION

Initial treatment should target bacterial and viral agents until culture results are confirmed or negative.

- Bacterial meningitis: vancomycin (15–20 mg/kg IV q6–8h, monitor levels) plus either cefotaxime (225–300 mg/kg/24 h IV q6–8h) or ceftriaxone (100 mg/kg/24 h IV divided q12–24h; use for ≥ 1 month old). Treat until cultures are negative at 48 hours.
- HSV encephalitis: acyclovir (>28 days— <12 years: 20 mg/kg/dose IV q8h; ≥ 12 years: 10 mg/kg/dose IV q8h). Acyclovir is continued for a minimum of 21 days if HSV is confirmed. PCR may be falsely negative in 5–10% of cases—contact an infectious diseases consultant if there is a high clinical suspicion. Monitor renal function while on acyclovir.
- Rickettsial infection (characteristic rash with exposure to ticks in an endemic region) or ehrlichiosis (headache, rash, leukopenia, thrombocytopenia, typical blood smear, transaminase elevation, with exposure to ticks in an endemic region): Consider empiric doxycycline.
- There is no evidence from controlled clinical trials that corticosteroids, IVIG, and therapeutic hypothermia are useful in cases of infectious encephalitis.
- Mycoplasma encephalopathy: erythromycin (benefit sustained from this medication is controversial given probable parainfectious mechanism)
- ADEM: high-dose IV corticosteroids 20–30 mg/kg/day \times 3 days followed by prednisolone taper. In refractory cases, either IVIG or

plasmapheresis can be considered.

- Anti-NMDA receptor encephalitis: high-dose IV corticosteroids, IVIG, or plasmapheresis. Rituximab has been used in combination with 1st-line agents.
- Immunotherapy is also recommended for other inflammatory or paraneoplastic causes of encephalitis.

INPATIENT CONSIDERATIONS

Initial Stabilization

- Careful attention to cardiorespiratory status is essential as is ruling out potential cerebral herniation. Children with severe encephalitis require intensive care with careful cardiorespiratory monitoring. Isolation precautions are based on type of suspected organism.
- Seizures: IV benzodiazepines (lorazepam, midazolam, or diazepam) are used acutely. Status epilepticus should be aggressively managed with a loading dose of fosphenytoin or levetiracetam. Barbiturate coma or midazolam infusion may be needed in refractory cases. In children with reduced level of consciousness, or those treated for refractory status epilepticus, EEG monitoring should be considered.
- Cerebral edema: Cerebral perfusion pressure should be kept at 70 mm Hg or higher for children older than 2 years of age. Conservative measures including fluid restriction, elevation of the head of the bed, and hyperventilation are most commonly used. With impending herniation, mannitol should be considered. Rarely, in malignant cases of cerebral edema, craniectomy can be considered for decompression.
- Investigation for occult tumors should be done with anti-NMDA receptor or other autoantibody-mediated encephalitis. Among girls with anti-NMDA receptor encephalitis, 9% younger than age 14 years and 30% younger than age 18 years were found to have an ovarian teratoma. Tumor resection is required to improve symptoms. Testicular teratoma has been rarely reported

IV Fluids

Closely monitor electrolytes, anticipating possible syndrome of inappropriate antidiuretic hormone or diabetes insipidus.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Physical and occupational therapists should be consulted early in the course and will be helpful during the convalescence.
- Neuropsychologic testing is helpful to identify cognitive deficits and direct appropriate services.
- Follow-up with speech pathologists and developmental pediatricians may be indicated.

PROGNOSIS

- Outcome varies greatly and depends on age, etiologic agent, and disease severity at the time of presentation (e.g., patients presenting in coma do worse).
- Outcomes range from complete recovery to focal neurologic deficits, persistent vegetative state, and death.
- Potential complications include aphasia, ataxia, developmental delay, learning disabilities, quadriparesis/hemiparesis, and epilepsy.

- G04.90 Encephalitis and encephalomyelitis, unspecified
- A85.8 Other specified viral encephalitis
- B00.4 Herpesviral encephalitis

FAQ

- Q: Will the child suffer permanent brain injury from encephalitis?
- A: The complications following encephalitis vary greatly from severe mental retardation and cerebral palsy to full recovery. There is a correlation between degree of brain destruction and outcome; however, children frequently recover better than adults with a similar degree of illness.
- A: Outcomes depend on the neurologic status of the patient at presentation and the causative organism. Although many children will make a full recovery, some have persisting neurologic problems including cognitive or motor difficulties, vision or hearing deficits, epilepsy, or personality change. Children with focal deficits or markedly impaired level of consciousness in the acute stage or those with HSV encephalitis are at highest risk of sequelae.
- Q: Is encephalitis highly contagious?
- A: Most cases of encephalitis are not highly contagious, although precautions should be followed with blood or body fluid exposure.

ENCOPRESIS

Jay Fong

BASICS

DESCRIPTION

- Repeated unintentional soiling of underwear
- Most commonly associated with functional constipation with severe stool retention and subsequent overflow incontinence:
 - 90% of cases of encopresis fall into this category.
- Another less common type of encopresis refers to the entity of repeated passage of feces into inappropriate places (usually clothing or floor) after the age of 4 years in the absence of constipation and structural or inflammatory diseases, also known as functional nonretentive fecal incontinence (FNRFI).

EPIDEMIOLOGY

- The reported ratio of boys to girls with encopresis ranges from 2:1 to 6:1.
- Boys are more likely to experience nonretentive fecal incontinence than girls at a ratio of 9:1.
- There is no association with family size, ordinal position in the family, age of parents, or socioeconomic status.
- Encopresis is reported in 1.5–2.8% of children >4 years of age.
- Between 10 and 30% of children with encopresis have nonretentive fecal incontinence.

RISK FACTORS

Genetics

Monozygotic twins have a 4-fold higher incidence than do dizygotic twins.

ALERT

- Constipation with a rectal fecal mass is most common risk for encopresis.
- Children with FNRFI have more behavioral problems, poor self-esteem, and higher prevalence of attention deficit disorder.

PATHOPHYSIOLOGY

Chronic constipation with fecal impaction results in overflow incontinence and reduced sensation secondary to rectal distention. The pattern of holding fecal matter, leading to chronic constipation and overflow incontinence, may result from a variety of causes, such as a painful experience from a fissure, difficult toilet training, or refusal to use school bathrooms. However, eliciting a medical history often does not reveal a triggering event.

ETIOLOGY

- Chronic constipation leads to a dilated rectum, decreased rectal sensation, shortening of the anal canal, and decreased anal sphincter tone in some patients.
- Findings on anorectal manometry include increased rectal sensory threshold and paradoxical contraction of the external anal sphincter during attempts at defecation (known as anismus).
- FNRFI occurs in children without constipation. The soiling may be a manifestation of an emotional disturbance, and it may be associated with specific triggers (person or place) or may represent an impulsive action triggered by unconscious anger. All studies in these patients are normal, including normal anorectal manometry and normal colonic transit times.

COMMONLY ASSOCIATED CONDITIONS

Enuresis is more frequently seen in patients with FNRFI (45% have daytime and 40% have nighttime enuresis) compared to constipated children.

DIAGNOSIS

HISTORY

- Toileting habits:
 - Constipation: frequency and size of bowel movements (large-diameter bowel movements are common in children with encopresis associated with functional constipation)

- Bowel movements that obstruct the toilet and/or chronic abdominal pain relieved by enemas or laxatives
- Retentive posturing: avoiding defecation by contraction of pelvic floor, squeezing the buttocks together (leg scissoring, crossing the legs, standing on tiptoes)
- Irritability, abdominal cramps, decreased appetite (symptoms improve after passage of large stool)
- Onset: Elicit history of triggering events (perianal infection, diet changes, toilet training, avoidance of school bathrooms, sexual abuse, or other stressful events).
- Enuresis (secondary daytime enuresis may occur in patients with megarectum compressing the bladder)
- Timing in the neonatal period of meconium passage, as well as past surgeries, medical history, and medications, are relevant.
- Unsteady or clumsy gait may suggest a neuromuscular disorder.
- Children with FNRFI do not have any history of constipation and have daily bowel movements. The incontinence is diurnal, usually in the afternoon.

PHYSICAL EXAM

- Encopresis with functional constipation
 - Fecal mass palpable in 40% of patients; fecal soiling in the perianal region
 - Dilated rectum with a normally positioned anus
- Digital rectal exam is not recommended to routinely diagnose fecal impaction or FNRFI.
 - Anal sphincter tone may be normal or slightly decreased; the anal canal is usually shorter than normal.
 - Hard stool or a large amount of “mushy” stool present in rectal vault
- FNRFI
 - No palpable fecal mass
 - Normal-size rectum
 - Normal sphincter length
- Examine deep tendon reflexes, anal wink, rectal exam, lumbosacral spine exam to look for sacral dimpling, and documentation of normal growth.

- In patients with extreme fear of anal exam, attempt a perianal inspection and obtain a plain radiograph of the abdomen to establish a fecal impaction.

DIAGNOSTIC TESTS & INTERPRETATION

Referral to a pediatric gastroenterologist for further evaluation, including anorectal manometry, may be useful for patients who are not responding to standard management.

Lab

No tests are needed if both the history and physical exam are consistent with functional constipation and associated encopresis. If the patient's history or physical exam is atypical and a systemic disorder is suspected, appropriate diagnostic tests should be done.

Imaging

- Abdominal radiography is often necessary for patients who refuse a rectal exam, or when a rectal impaction is not palpable on abdominal exam (e.g., in obese patients).
- Enema with water-soluble contrast material can be both helpful diagnostically to look for areas of narrowing and therapeutically as a clean out procedure.
- MRI of the spine can be done for children with suspected spinal abnormalities. This is rarely necessary if the neurologic exam is normal.
- Colonic transit study with radio-opaque markers to confirm the patients' complaints or assess for slow transit constipation

Diagnostic Procedures/Other

- Rectal suction biopsy can be performed to evaluate for ganglion cells within the colonic mucosa and definitively evaluate for Hirschsprung disease.
- Anorectal manometry can be done in selected cases to evaluate anorectal function. The main indication is to demonstrate the rectoanal inhibitory reflex to exclude Hirschsprung disease and ultra-short-segment Hirschsprung disease. It may also show an increased threshold to rectal sensation, providing important information to the patient and the parents.

DIFFERENTIAL DIAGNOSIS

Determine whether stool leakage is caused by functional constipation or an underlying anatomic, metabolic, or neurologic abnormality. Fecal incontinence may be secondary to diarrheal diseases or defective neuromuscular control, such as in children with spinal defects.

- Neuromuscular
 - Spinal cord tumor
 - Tethered spinal cord
 - Meningomyelocele
- Anal abnormalities:
 - Anteriorly displaced anus
 - Ectopic anus
- Inflammatory
 - Proctitis (infectious or ulcerative)
 - Fistula secondary to Crohn disease
 - Celiac disease
- Stricture (after necrotizing enterocolitis or inflammatory bowel disease)
- Abdominal pelvic mass (sacral teratoma, meningomyelocele)
- Hypotonia (cerebral palsy, amyotonia congenita, familial visceral myopathy)
- Hirschsprung disease (constipation common, fecal incontinence rarely seen) or ultra-short-segment Hirschsprung disease
- Postsurgical repair of imperforate anus or Hirschsprung disease
- Endocrine
 - Hypothyroidism
 - Panhypopituitarism
 - Diabetes mellitus
- Constipating drugs:
 - Opiates
 - Calcium supplements
 - Psychotropics

TREATMENT

MEDICATION

- Evidence suggests fecal disimpaction can be equally achieved with either oral PEG (with or without electrolytes at 1–1.5 g/kg/24 h) for 3–6 days of enemas or enema therapies. Sedated manual disimpaction is rarely required.
 - Severe cases may require PEG ingestion by NG tube after disimpaction in a hospital setting.
- Stimulant laxatives:
 - Magnesium citrate
 - Bisacodyl
 - Senna
- Oral stool softeners:
 - PEG-3350 (0.75 mg/kg/24 h) is the preferred agent because of its palatability and ease of administration.
 - Lactulose (2.5–10 mL/24 h for infants and 40–90 mL/day in older children) is recommended as the 1st-line treatment if PEG-3350 is not available.
 - Milk of magnesia (0.5–1 mL/kg/24 h) is a good option.
 - Mineral oil (5–20 mL in divided doses) may also be used in older children who have no risk of aspiration.

ISSUES FOR REFERRAL

Patients with nonretentive fecal incontinence usually require referral to a mental health professional for more intensive behavioral intervention.

COMPLEMENTARY & ALTERNATIVE THERAPIES

- Behavior modification therapy: decrease family stress. Have the child sit on toilet for defined amount of time (1 min/year of age to a maximum of 10 minutes) 1–2 times per day (ideally after a meal, tailored to the age of the child) and try to perform a Valsalva maneuver. Have young children blow into a pinwheel or a balloon to try to make them bear down.
- Use a sticker incentive chart if age-appropriate.
- Delay toilet training if the child is in diapers (to reduce stress).
- Motivate using positive reinforcement strategies. Biofeedback can be successful in some cases.

INPATIENT CONSIDERATIONS

Initial Stabilization

Management combines pharmacology, behavioral modification, and dietary alterations.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- First follow-up visit is at 2 weeks to ensure compliance and success with the initial management.
- If the fecal impaction has been successfully removed, a reward system is started.
- The patient is followed at monthly intervals to ensure motivation and to be supportive.
- Treatment with stool softeners is needed until behavior and diet have improved and until rectal dilation has resolved.
- Medication is often needed for 6 months or longer.

ALERT

- Parents may misconstrue stool-withholding behavior as an attempt to defecate.
- Parents may think that the soiling represents diarrheal illness, causing a delay in diagnosis and treatment.
- Parents may think their child's soiling is deliberate. They may not understand that the child can neither feel the passage of stool nor prevent it. The usual urge to defecate, which comes from stretching of the ampulla and internal anal sphincter, is not felt because the rectal ampulla is massively distended.
- Patients or their parents often stop stool softeners as soon as a normal stool pattern starts. If therapy has been ended prematurely, the patient's constipation and encopresis returns immediately because rectal tone is still poor and no other behavior or dietary modifications have been made.

DIET

- Normal fiber intake
- Adequate fluid intake

COMPLICATIONS

- Social problems
- UTIs, especially in girls
- Abdominal discomfort
- Decreased appetite and weight loss

CODES

ICD10

- R15.9 Full incontinence of feces
- F98.1 Encopresis not due to a substance or known physiol condition

FAQ

- Q: Is it possible to become “addicted” to laxative medicines?

- A: Stool softeners, rather than cathartic laxatives or per rectal therapies are chosen for long-term therapy because the colon does not become dependent.
- Q: Will my child become sick if this problem is not resolved?
- A: Most children with chronic constipation and encopresis grow well and do not develop other health problems. The major problems are social and should be taken seriously. Social continence is crucial for the school-aged child.

ENDOCARDITIS

Jenifer A. Glatz

BASICS

DESCRIPTION

Infective endocarditis (IE) is a microbial infection of the endocardium of the heart.

EPIDEMIOLOGY

Incidence

- IE is relatively uncommon. The estimated incidence is 0.3 per 100,000 children per year.
